In this article, we construct a categorification of some Fourier matrices associated to complex reflections groups by Malle [Ma95]. To any special imprimitive complex reflection group $W$, he attached a set of unipotent characters, which is in bijection with the set of unipotent characters of the corresponding finite reductive group when $W$ is a Weyl group. He also defined a partition of these characters into families, the analogue of Lusztig’s non abelian Fourier transform and eigenvalues of the Frobenius. In [Cun07], Cuntz showed that for each family, this defines a so-called $\mathbb{Z}$-modular datum. Therefore, one can associate a $\mathbb{Z}$-algebra, free of finite rank over $\mathbb{Z}$. If the structure constants of such an algebra $R$ are positive, it is a classical problem to find a tensor category, with some extra structure, whose Grothendieck ring is precisely $R$. However, these structure constants belong in general to $\mathbb{Z}$ and the categorification is more involved.

In the case of cyclic groups, Bonnafé and Rouquier [BR17] constructed a tensor triangulated category which categorifies the modular datum attached to the non-trivial family of the cyclic spets. In the present article, we construct fusion categories with symmetric center equivalent to $\text{Rep}(G, z)$ for $G$ a cyclic group and $z \in G$ satisfying $z^2 = 1$. If the order of $G$ is even, we can therefore construct a new category, which is enriched over superspaces, so that its Grothendieck group have negative structure constants in general. As shown in [Lac18], this defines a $\mathbb{Z}$-modular datum.

Our construction is as follows: we consider the representation theory of a quantum double associated to the complex simple Lie algebra $\mathfrak{sl}_{n+1}$ at an even root of unity. Similarly to the usual construction for $U_q(\mathfrak{g})$ at a root of unity, we consider the semisimplification of the full subcategory of tilting modules. A partial modularization of an integral subcategory gives then the category with symmetric center $\text{Rep}(G, z)$.

We investigate this construction in full generality considering any simple complex Lie algebra $\mathfrak{g}$ and any root of unity. Indeed, some fusion datum constructed by Broué, Malle and Michel for special exceptional complex reflection groups can be categorified by considering similar categories in type $B$.

Acknowledgements. — I warmly thank my advisor C. Bonnafé for many fruitful discussions and his constant support. I also thank R. Rouquier for suggesting me to consider supercategories in this work.
1. Quantum double of Borel algebras

In this section, we recall the construction of the quantum enveloping algebra \( U_q(g) \) associated to a simple complex Lie algebra \( g \). Our main object of study will be the quantum double of a Borel algebra \( b \) of \( g \), which will be denoted by \( \mathcal{D}_q(g) \).

1.1. Notations. — Let \( g \) be a simple complex Lie algebra of rank \( n \). We fix a Cartan subalgebra \( h \) of \( g \). Let \( \Phi \subseteq h^\ast \) be the set of roots of \( g \) relative to \( h \), \( \Pi = \{\alpha_1, \ldots, \alpha_n\} \) be a basis of \( \Phi \), \( \Phi^+ \) be the positive roots relative to \( \Pi \). Let \( b^+ \) (resp. \( b^- \)) be the Borel subalgebra of \( g \) relative to \( \Pi \) (resp. \( -\Pi \)). We denote by \( h \) the Coxeter number of \( g \) and by \( h^\vee \) the dual Coxeter number of \( g \).

Fix a symmetric bilinear form \( \langle \cdot, \cdot \rangle \) on \( h^\ast \) normalized such that \( \langle a, a \rangle = 2 \) for short roots. Let \( D = \max_{\alpha, \beta \in \Phi} \langle \alpha, \beta \rangle \). We have \( D = 1 \) in type \( A \), \( D = 2 \) in type \( B, C \) or \( F_4 \) and \( D = 3 \) in type \( G_2 \). For \( a \in \Phi \), we define \( a^\vee \in h^\ast \) by

\[
a^\vee = \frac{2a}{\langle a, a \rangle}.
\]

Let \( Q \) be the root lattice, \( P \) the weight lattice, \( P^+ \) the cone of dominant weights, \( Q^\vee \) the coroot lattice and \( P^\vee \) the coweight lattice

\[
P = \{\lambda \in h^\ast | \langle \lambda, a^\vee \rangle \in \mathbb{Z}, \forall a \in \Pi\}
\]

\[
P^\vee = \{\lambda \in h^\ast | \langle \lambda, a \rangle \in \mathbb{Z}, \forall a \in \Pi\}
\]

\[
P^+ = \{\lambda \in h^\ast | \langle \lambda, a^\vee \rangle \in \mathbb{N}, \forall a \in \Pi\}
\]

\[
P^- = \{\lambda \in h^\ast | \langle \lambda, a \rangle \in \mathbb{N}, \forall a \in \Pi\}
\]

Let \( (\sigma_i)_{1 \leq i \leq n} \) be the dual basis of \( (a_i^\vee)_{1 \leq i \leq n} \) with respect to the form \( \langle \cdot, \cdot \rangle \) and \( \rho \) be the half sum of positive roots. We call the \( \sigma_i \)'s the fundamental weights. The element \( \rho \) is in \( P \) and is equal to the sum of fundamental weights [Bou68, VI.1.10 Proposition 29].

We denote by \( Q^+ \) the monoid spanned by \( \Pi \). We denote by \( \leq \) the usual partial order on \( P \): \( \lambda \leq \mu \) if and only if \( \mu - \lambda \in Q^+ \).

For any \( a \in \Phi \), denote by \( s_a \) the reflection in the hyperplane orthogonal to \( a \)

\[
s_a(v) = v - \langle v, a^\vee \rangle a = v - \langle v, a \rangle a^\vee, \quad \forall v \in h^\ast.
\]

For \( 1 \leq i \leq n \) denote by \( s_i \) the reflection \( s_{\alpha_i} \). All these reflections generate the Weyl group \( W \) of \( g \) and for any \( w \in W \), \( w(\Phi) = \Phi \). The form \( \langle \cdot, \cdot \rangle \) is then invariant with respect to \( W \).

We denote by \( l(w) \) the length of \( w \in W \) relative to the generating set \( (s_i)_{1 \leq i \leq n} \).

For \( q \) an indeterminate, define the following elements of \( \mathbb{Z}[q, q^{-1}] \)

\[
[n]_q = \frac{q^n - q^{-n}}{q - q^{-1}}, n \in \mathbb{Z}, \quad [n]_q! = \prod_{k=1}^{n} [k]_q, n \in \mathbb{N} \quad \text{and} \quad \left[ \begin{array}{c} n \\ k \end{array} \right]_q = \prod_{i=1}^{k} \frac{[n+1-i]_q}{[i]_q}, n \in \mathbb{Z}, k \in \mathbb{N}.
\]

We denote by \( [n]_\xi \) (resp. \( [n]_\xi! \), resp. \( \left[ \begin{array}{c} n \\ k \end{array} \right]_\xi \)) the evaluation of \( [n]_q \) (resp. \( [n]_q! \), resp. \( \left[ \begin{array}{c} n \\ k \end{array} \right]_q \)) at an invertible element \( \xi \) of a ring. Let \( L \) be the smallest integer such that \( L(\lambda, \mu) \in \mathbb{Z} \) for any \( \lambda, \mu \in P \). Let \( s \) be an indeterminate and let \( q = s^L \). We will work over the field \( \mathbb{Q}(s) \) and the ring \( \mathcal{O} = \mathbb{Z}[s, s^{-1}] \). We define \( q_i = q^{\langle a_i, a_i \rangle} \).

1.2. Positive and negative parts of the usual quantum enveloping algebra. — We start by defining the usual positive and negative part of the quantum group \( \mathcal{U}_q(g) \).
Proposition 1.3. — \( \forall x \) for all \( i \leq j \leq n \), \( K_i K_j = K_j K_i \), \( K_i K_j^{-1} = K_j^{-1} K_i \), \( \forall 1 \leq i, j \leq n \),
\[ K_i E_j = q^{(a_i, a_j)} E_j K_i, \quad \forall 1 \leq i, j \leq n, \]
\[ \sum_{r=0}^{1-(a_i, a_j)} (-1)^r \left[ 1 - \frac{(a_i, a_j)}{r} \right] E_i E_j^{(a_i, a_j)-r} = 0, \quad \forall 1 \leq i \neq j \leq n. \]

There exist several Hopf algebra structures on \( \mathcal{U}_q(b^+) \), and we choose the following comultiplication \( \Delta \), counit \( \varepsilon \) and antipode \( S \):
\[ \Delta(K_i) = K_i \otimes K_i \quad \varepsilon(K_i) = 1 \quad S(K_i) = K_i^{-1}, \]
\[ \Delta(E_i) = 1 \otimes E_i + E_i \otimes K_i \quad \varepsilon(E_i) = 0 \quad S(E_i) = -E_i K_i^{-1}. \]

Definition 1.2. — Let \( \mathcal{U}_q(b^-) \) be the associative unital \( \mathbb{Q}(s) \)-algebra with generators \( L_i^{\pm 1}, F_i, \alpha \in \Phi \), and defining relations
\[ L_i L_j = L_j L_i, \quad L_i L_i^{-1} = 1 = L_i^{-1} L_i, \quad \forall 1 \leq i, j \leq n, \]
\[ L_i F_j = q^{-a_i a_j} F_j L_i, \quad \forall 1 \leq i, j \leq n, \]
\[ \sum_{r=0}^{1-(a_i, a_j)} (-1)^r \left[ 1 - \frac{(a_i, a_j)}{r} \right] F_i^{(a_i, a_j)-r} F_j F_i^{(a_i, a_j)-r} = 0, \quad \forall 1 \leq i \neq j \leq n. \]

There exist several Hopf algebra structures on \( \mathcal{U}_q(b^-) \), and we choose the following comultiplication \( \Delta \), counit \( \varepsilon \) and antipode \( S \):
\[ \Delta(L_i) = L_i \otimes L_i \quad \varepsilon(L_i) = 1 \quad S(L_i) = L_i^{-1}, \]
\[ \Delta(F_i) = L_i^{-1} \otimes F_i + F_i \otimes 1 \quad \varepsilon(F_i) = 0 \quad S(F_i) = -L_i F_i. \]

For \( \lambda = \sum_{i=1}^{n} \lambda_i a_i \), we denote by \( K_\lambda \) (resp. \( L_\lambda \)) the element \( \prod_{i=1}^{n} K_i^{\lambda_i} \) (resp. \( \prod_{i=1}^{n} L_i^{\lambda_i} \)).

1.3. A Hopf pairing between \( \mathcal{U}_q(b^+) \) and \( \mathcal{U}_q(b^-) \). — The following is due to Drinfeld [Dri87 Section 13] and has been studied by Tanisaki [Tan92].

Proposition 1.3. — There exists a unique bilinear form \( (\cdot, \cdot) : \mathcal{U}_q(b^+) \times \mathcal{U}_q(b^-) \to \mathbb{Q}(s) \) satisfying for all \( x, x' \in \mathcal{U}_q(b^+) \), \( y, y' \in \mathcal{U}_q(b^-) \) and \( 1 \leq i \leq n \):
1. \( (x, y y') = (\Delta(x), y \otimes y') \),
2. \( (x x', y) = (x' \otimes x, \Delta(y)) \),
3. \( (x, 1) = \varepsilon(x), (1, y) = \varepsilon(y) \),
4. \( (K_i, L_j) = q^{a_i a_j} \),
5. \( (K_i, F_j) = 0 = (E_i, L_j) \),
6. \( (E_i, F_j) = \delta_{i,j} q^{-a_i a_j} \).

This bilinear form endows the tensor product \( \mathcal{U}_q(b^-) \otimes \mathcal{U}_q(b^+) \) with a Hopf algebra structure, which we denote by \( \mathcal{U}_q(g) \), see [KS97 Section 8.2]. Using Sweedler notation for the coproduct, the product of \( y_1 \otimes x_1 \) and \( y_2 \otimes x_2 \) in \( \mathcal{U}_q(b^-) \otimes \mathcal{U}_q(b^+) \) is given by
\[ (y_1 \otimes x_1)(y_2 \otimes x_2) = \sum_{(x_1)j_2} (x_1', y_2') (x_1'', S(y_2'')) y_1 y_2'' \otimes x_1' x_2. \]
Proposition 1.4. — The algebra $\mathcal{D}_q(g)$ is the associative unital $\mathbb{Q}(s)$-algebra with generators $K_i^\pm 1, L_i^\pm 1, E_i$ and $F_i, 1 \leq i \leq n$ and defining relations

\[
K_i K_j = K_j K_i, \quad K_i K_i^{-1} = 1 = K_i^{-1} K_i, \quad L_i L_j = L_j L_i, \quad L_i L_i^{-1} = 1 = L_i^{-1} L_i, \quad K_i L_j = L_j K_i, \quad K_i F_j = q^{(a_i, a_j)} F_j K_i, \quad L_i F_j = q^{(a_i, a_j)} F_j L_i, \quad [E_i, F_j] = \delta_{i,j} K_i^{-1} L_i^{-1}, \]

\[
\sum_{r=0}^{1-(a_i, a_j)^\vee} (-1)^r \left[ 1 - \binom{a_i, a_j}{r} \right] E_i^{-1(a_i, a_j)^\vee - r} E_i E_i^r = 0, \quad 1 \leq i \neq j \leq n, \]

\[
\sum_{r=0}^{1-(a_i, a_j)^\vee} (-1)^r \left[ 1 - \binom{a_i, a_j}{r} \right] F_i^{-1(a_i, a_j)^\vee - r} F_i F_i^r = 0, \quad 1 \leq i \neq j \leq n. \]

The elements $z_i = K_i L_i^{-1}$ are central and $\mathcal{U}_{q}(g)$ is the quotient of $\mathcal{D}_q(g)$ by the Hopf ideal generated by $(z_i - 1)_{1 \leq i \leq n}$.

Denote by $\mathcal{D}_q(g)^{>0}$ (resp. $\mathcal{D}_q(g)^0$, resp. $\mathcal{D}_q(g)^{<0}$) the subalgebra of $\mathcal{D}_q(g)$ generated by $(E_i)_{1 \leq i \leq n}$ (resp. $(F_i)_{1 \leq i \leq n}$, resp. $(K_i, L_i)_{1 \leq i \leq n}$). Multiplication yields an isomorphism $\mathcal{D}_q(g)^{>0} \otimes \mathcal{D}_q(g)^0 \otimes \mathcal{D}_q(g)^{<0} \simeq \mathcal{D}_q(g)$. It is worth mentioning that the coproduct and antipode of $\mathcal{D}_q(g)$ do not restrict to $\mathcal{D}_q(g)^{>0}$ or $\mathcal{D}_q(g)^{<0}$.

The square of the antipode is given by the conjugation by any element of the form $L_{\lambda} K_{2p-\lambda}, \lambda \in Q$ as it is easily checked on the generators.

1.4. Graduation. — There exists a $Q$-graduation on $\mathcal{D}_q(g)$ given by $\deg(K_i) = 0 = \deg(L_i)$, $\deg(E_i) = a_i$ and $\deg(F_i) = -a_i$. For $\lambda \in Q$, we denote by $\mathcal{D}_q(g)_\lambda$ the homogeneous elements of degree $\lambda$. We have

\[
\mathcal{D}_q(g)_\lambda = \{ v \in \mathcal{D}_q(g) \mid K_i v = q^{(\lambda, a_i)} v K_i, \ \forall 1 \leq i \leq n \}.
\]

The coproduct, the counit and the antipode respect the grading. Moreover, the same lemma as [Jan96] lemma 4.12 shows that for $\mu \in Q, \mu \geq 0$

\[
\Delta\left(\mathcal{D}_q(g)^{>0}_\mu\right) \subseteq \bigoplus_{0 \leq r \leq \mu} \mathcal{D}_q(g)^{>0}_\nu \otimes K_r \mathcal{D}_q(g)^{>0}_{\mu - \nu}
\]

and

\[
\Delta\left(\mathcal{D}_q(g)^{<0}_\mu\right) \subseteq \bigoplus_{0 \leq r \leq \mu} L_r^{-1} \mathcal{D}_q(g)^{<0}_{\mu - \nu} \otimes \mathcal{D}_q(g)^{<0}_{\nu - r}.
\]

Therefore, for $x \in \mathcal{D}_q(g)^{>0}_\mu$, there are elements $r_i(x)$ and $r_i'(x)$ in $\mathcal{D}_q(g)^{>0}_{\mu - a_i}$ such that
(1) \[ \Delta(x) = 1 \otimes x + \sum_{i=1}^{n} E_i \otimes K_i r_i(x) + \sum_{0 \leq y \leq \mu \atop \nu \notin U} D_q(g)_{y}^{-} \otimes K_y D_q(g)_{\mu - \nu}^{-} \]

and

(2) \[ \Delta(x) = x \otimes K_\mu + \sum_{i=1}^{n} r_i'(x) \otimes K_\mu - \alpha_i E_i + \sum_{0 \leq y \leq \mu \atop \nu \notin U} D_q(g)_{y}^{-} \otimes K_y D_q(g)_{\mu - \nu}^{-}. \]

Similarly, we can define \( \rho_i(y) \) and \( \rho_i'(y) \) for \( y \in D_q(g)_{\mu}^{-} \) by the following

\[ \Delta(y) = y \otimes 1 + \sum_{i=1}^{n} L^{-1}_{\mu - \alpha_i} F_i \otimes \rho_i(y) + \sum_{0 \leq y \leq \mu \atop \nu \notin U} L^{-1}_{\nu} D_q(g)_{y}^{-} \otimes D_q(g)_{\mu - y}^{-}, \]

and

\[ \Delta(y) = L^{-1}_{\mu} \otimes y + \sum_{i=1}^{n} L^{-1}_{\mu - \alpha_i} \rho_i'(y) \otimes F_i + \sum_{0 \leq y \leq \mu \atop \nu \notin U} L^{-1}_{\nu} D_q(g)_{y}^{-} \otimes D_q(g)_{\mu - y}^{-}. \]

The values of \( r_i, r_i', \rho_i \) and \( \rho_i' \) can be computed by induction. Compare with [Jan96 6.14,6.15].

**Lemma 1.5.** — Let \( \mu, \mu' \in Q, \mu \geq 0 \) and \( \mu' \geq 0. \)

1. For all \( x \in D_q(g)_{\mu}^{0} \) and \( x' \in D_q(g)_{\mu'}^{0}, \)
   \[ r_i(x x') = q^{-(\alpha_i, \mu)} x r_i(x') + r_i(x) x' \]
   \[ r_i'(x x') = x r_i'(x') + q^{-(\alpha_i, \mu')} r_i'(x) x'. \]

2. For all \( y \in D_q(g)_{\mu}^{<0} \) and \( y' \in D_q(g)_{\mu'}^{<0}, \)
   \[ \rho_i(y y') = y \rho_i(y') + q^{-(\alpha_i, \mu')} \rho_i(y) y' \]
   \[ \rho_i'(y y') = q^{-(\alpha_i, \mu)} y \rho_i'(y') + \rho_i'(y) y'. \]

These elements can also be used to compute some commutators.

**Lemma 1.6.** — Let \( \mu \in Q, \mu \geq 0. \) Let \( x \in D_q(g)_{\mu}^{0} \) and \( y \in D_q(g)_{\mu}^{<0}. \) Then

\[ x F_i - F_i x = \frac{K_i r_i(x) - r_i'(x) L^{-1}_i}{q_i - q_i^{-1}} \]

and

\[ E_i y - y E_i = \frac{\rho_i(y) K_i - L^{-1}_i \rho_i'(y)}{q_i - q_i^{-1}}. \]

**Proof.** — We only show the first formula, the second one is proven similarly. If \( x = 1 \) or \( x = E_i, \) the formula is satisfied. Now, supposing that it is true for \( x \) and \( x', \) we show it for \( x x': \)

\[ x x' F_i - F_i x x' = (x x' F_i - F_i x') + (x F_i - F_i x) x' \]
\[ = (q_i - q_i^{-1})^{-1} (x (K_i r_i(x') - r_i'(x') L^{-1}_i) + (K_i r_i(x) - r_i'(x) L^{-1}_i) x') \]
\[ = (q_i - q_i^{-1})^{-1} (K_i (q^{-(\alpha_i, \mu)} x r_i(x') + r_i(x) x') - (x r_i'(x') + q^{-(\alpha_i, \mu')} r_i'(x) x')) \]
\[ = (q_i - q_i^{-1})^{-1} (K_i r_i(x x') - r_i'(x x') L^{-1}_i), \]

where we used Lemma 1.5 in the last equality. \( \square \)
1.5. Some properties of the pairing. — We gather here some well known properties of the pairing.

**Proposition 1.7.** Let \( x \in \mathcal{D}_q(\mathfrak{g})^{>0}, \) \( y \in \mathcal{D}_q(\mathfrak{g})^{<0} \) and \( \lambda, \mu \in Q. \) Then

1. \( (K_\lambda x, L_\mu y) = (K_\lambda, L_\mu)(x, y). \)
2. Suppose \( \lambda, \mu \geq 0. \) If \( x \) is of weight \( \lambda \) and \( y \) of weight \( -\mu \) then \( (x, y) = 0 \) if \( \lambda \neq \mu. \)

**Proof.** For the first equality, it suffices to show it for \( x \) and \( y \) homogeneous. It then follows easily from (1), (2) and the fact that \( (K_\lambda, y') = 0 = (x', L_\mu) \) for any \( x' \in \mathcal{D}_q(\mathfrak{g})^{>0} \) and \( y' \in \mathcal{D}_q(\mathfrak{g})^{<0}. \)

For the second assertion, we proceed by induction on \( \text{ht}(\lambda) = \sum_{i=1}^n \lambda_i \), where \( \lambda = \sum_{i=1}^n \lambda_i a_i. \) We can suppose that \( x \) is a product of the generators \( E_i. \) The case \( \text{ht}(\lambda) = 1, \) i.e. \( \lambda \in \Pi \) is easily proved by induction on \( \text{ht}(\mu). \) Then, writing \( x = E_i x' \) and \( y = E_i y' \), one has

\[
\Delta(y) = \sum_{0 \leq i \leq \rho} L_y^{1} y'_{-(y_{1-\rho})} \otimes y''_{y}, \quad y', y'' \in \mathcal{D}_q(\mathfrak{g})^{<0},
\]

As \( \lambda \neq \mu, \) the two terms can not be simultaneously non-zero.

Using these two facts and an easy induction, one can show that, for \( 1 \leq i \leq n, \) and \( r \in \mathbb{N}, \)

\[
(E_i^r, F_i^r) = \frac{q_i^{r+1}}{(q_i - q_i^{1})^r}.
\]

We now turn to the compatibility between the pairing and the \( r_i, r_i', \rho_i \) and \( \rho_i' \) defined in section [1.4]

**Lemma 1.8.** Let \( x \in \mathcal{D}_q(\mathfrak{g})^{>0} \) and \( y \in \mathcal{D}_q(\mathfrak{g})^{<0}. \) One has

\[
(x, F_i y) = (E_i, F_i)(r_i(x), y), \quad (x, y F_i) = (E_i, F_i)(r_i'(x), y),
\]

\[
(E_i x, y) = (E_i, F_i)(x, \rho_i'(y)), \quad (x E_i, y) = (E_i, F_i)(x, \rho_i(y)).
\]

**Proof.** It follows easily from (1), (2) and Proposition 1.7.

We end this section with [Tan92, Proposition 2.1.4]

**Proposition 1.9.** The restriction of the pairing to \( \mathcal{D}_q(\mathfrak{g})^{>0} \times \mathcal{D}_q(\mathfrak{g})^{<0} \) is non-degenerate.

1.6. Basis for \( \mathcal{D}_q(\mathfrak{g}). \) — We introduce the divided power \( E_i^{(r)} \) and \( F_i^{(r)} \) for \( 1 \leq i \leq n: \)

\[
E_i^{(r)} = \frac{E_i^r}{[r]_{q_i}} \quad \text{and} \quad F_i^{(r)} = \frac{F_i^r}{[r]_{q_i}}.
\]

The following is the analogue of [Lus90, Theorem 3.1] for \( \mathcal{D}_q(\mathfrak{g}). \)

**Proposition 1.10.** For all \( 1 \leq i \leq n, \) there exists a unique \( Q(\mathfrak{s}) \)-algebra isomorphism \( T_i \) such that:

\[
T_i(K_\lambda) = K_{s(\lambda)} \quad T_i(L_\lambda) = L_{s(\lambda)}, \quad \forall \lambda \in Q,
\]
and, for $1 \leq j \leq n$, setting $r = -\langle \alpha_j, \alpha_i^\vee \rangle$,

$$T_i(E_j) = \begin{cases} -F_i E_j & \text{if } i = j, \\ \sum_{k=0}^{r} (-1)^k q_i^{-k} E_i^{(r-k)} E_j F_i^{(k)} & \text{otherwise,} \end{cases}$$

$$T_i(F_j) = \begin{cases} -K_i^{-1} E_i & \text{if } i = j, \\ \sum_{k=0}^{r} (-1)^k q_i^{-k} F_i^{(r-k)} F_j F_i^{(k)} & \text{otherwise,} \end{cases}$$

We also have the analogue of [Lus90] Theorem 3.2] for $\mathcal{D}_q(g)$.

**Proposition 1.11.** — The $(T_i)_{1 \leq i \leq n}$ satisfy the braid relations and therefore define a morphism from the braid group of $W$ to the algebra automorphisms of $\mathcal{D}_q(g)$.

Choose now a reduced decomposition $w_0 = s_{i_1} s_{i_2} \cdots s_{i_r}$ of the longest element $w_0$ of $W$. The positive roots are then

$$\Phi^+ = \{ s_{i_1} s_{i_2} \cdots s_{i_k} (\alpha_{i_{k+1}}) | 0 \leq k \leq r - 1 \}.$$

For any $\alpha = s_{i_1} s_{i_2} \cdots s_{i_k} (\alpha_{i_{k+1}}) \in \Phi^+$ define

$$E_\alpha = T_{i_1} T_{i_2} \cdots T_{i_k} (E_{i_{k+1}}) \quad \text{and} \quad F_\alpha = T_{i_1} T_{i_2} \cdots T_{i_k} (F_{i_{k+1}})$$

Note that $E_\alpha$ (resp $F_\alpha$) is homogeneous of degree $\alpha$ (resp $-\alpha$). The choice of a reduced decomposition of $w_0$ gives an order on $\Phi^+$, namely $s_{i_1} s_{i_2} \cdots s_{i_k} (\alpha_{i_{k+1}}) \leq s_{i_1} s_{i_2} \cdots s_{i_{k+1}} (\alpha_{i_{k+2}})$ for every $k$. All products will be ordered with this order.

**Proposition 1.12 ([Lus90] Theorem 6.7).** — The elements

$$\prod_{\alpha \in \Phi^+} E_{\alpha}^{(n_{\alpha})}, \ n_{\alpha} \in \mathbb{N}$$

form a $\mathbb{Q}(s)$-basis of $\mathcal{D}_q(g)^{>0}$. The elements

$$\prod_{\alpha \in \Phi^+} F_{\alpha}^{(n_{\alpha})}, \ n_{\alpha} \in \mathbb{N}$$

form a $\mathbb{Q}(s)$-basis of $\mathcal{D}_q(g)^{<0}$.

We compute now the dual basis of $\mathcal{D}_q(g)^{>0}$ with respect to $\langle \cdot, \cdot \rangle$. The following can be found in [Jan96] 8.29.

**Proposition 1.13.** — For any $\alpha \in \Phi^+$, let $a_\alpha, b_\alpha \in \mathbb{N}$. We have

$$\left( \prod_{\alpha \in \Phi^+} E_{\alpha}^{a_{\alpha}}, \prod_{\alpha \in \Phi^+} F_{\alpha}^{b_{\alpha}} \right) = \prod_{\alpha \in \Phi^+} \delta_{a_{\alpha}, b_{\alpha}} \frac{q_{\alpha}^{a_{\alpha}(a_{\alpha} - 1)/2}}{(q_{\alpha} - q_{\alpha}^{-1})^{a_{\alpha}}}. $$

Therefore, the dual basis of $(\prod_{\alpha \in \Phi^+} E_{\alpha}^{(n_{\alpha})})_{(n_{\alpha}) \in \mathbb{N}^{\Phi^+}}$ is

$$\left( \prod_{\alpha \in \Phi^+} q_{\alpha}^{a_{\alpha}(a_{\alpha} - 1)/2} (q_{\alpha} - q_{\alpha}^{-1})^{a_{\alpha}} E_{\alpha}^{(n_{\alpha})} \right)_{(n_{\alpha}) \in \mathbb{N}^{\Phi^+}}.$$
1.7. Quasi-R-matrix. — The algebra $\mathcal{D}_q(g)$ is not quasi-triangular. Nevertheless, we construct a quasi-R-matrix which will endow the usual category of modules with a braiding (see section 2.3). We adapt the exposition of Jantzen [Jan96, Chapter 7] to the case of $\mathcal{D}_q(g)$.

For any $\mu \in Q$, $\mu \geq 0$, fix a basis $(u^{\mu}_i)_{i \in I}$ of $\mathcal{D}_q(g)_{\mu}$ and let $(v^{\mu}_i)_{i \in I}$ the dual basis in $\mathcal{D}_q(g)_{-\mu}$ with respect to the pairing $D$. Set

$$\Theta_\mu = \sum_{i \in I} u^{\mu}_i \otimes v^{\mu}_i \in \mathcal{D}_q(g) \otimes \mathcal{D}_q(g).$$

Note that this does not depend on the choice of the basis of $\mathcal{D}_q(g)_{\mu}$. A homogeneous basis of $\mathcal{D}_q(g)^{\geq 0}$ and its dual with respect to $D$ have already been computed above. Following [Ros90, A.1], we define an algebra automorphism $\Psi$ of $\mathcal{D}_q(g) \otimes \mathcal{D}_q(g)$ by

$$\Psi(K_i \otimes 1) = K_i \otimes 1, \quad \Psi(1 \otimes K_i) = 1 \otimes K_i,$$
$$\Psi(L_i \otimes 1) = L_i \otimes 1, \quad \Psi(1 \otimes L_i) = 1 \otimes L_i,$$
$$\Psi(E_i \otimes 1) = E_i \otimes L_i^{-1}, \quad \Psi(1 \otimes E_i) = K_i^{-1} \otimes E_i,$$
$$\Psi(F_i \otimes 1) = F_i \otimes L_i, \quad \Psi(1 \otimes F_i) = K_i \otimes F_i.$$  

**Proposition 1.14.** — Let $\mu \in Q$, $\mu \geq 0$. We have

$$\Theta_\mu(K_i \otimes K_i) = \Psi(K_i \otimes K_i) \Theta_\mu,$$
$$\Theta_\mu(L_i \otimes L_i) = \Psi(L_i \otimes L_i) \Theta_\mu,$$
$$\Theta_\mu(1 \otimes E_i) + \Theta_{\mu-a_i}(E_i \otimes K_i) = \Psi(E_i \otimes 1) \Theta_{\mu-a_i} + \Psi(K_i \otimes E_i) \Theta_\mu,$$
$$\Theta_\mu(F_i \otimes 1) + \Theta_{\mu-a_i}(L_i^{-1} \otimes F_i) = \Psi(1 \otimes F_i) \Theta_{\mu-a_i} + \Psi(F_i \otimes L_i^{-1}) \Theta_\mu.$$

**Proof.** — We follow closely the proof of [Jan96, Lemma 7.1]. The first two equations are trivial. We will use the following fact: for any $\mu \in Q$, $\mu \geq 0$, and any $x \in \mathcal{D}_q(g)_{\mu}^0$ and $y \in \mathcal{D}_q(g)_{-\mu}$ we have

$$x = \sum_i (x, u^{\mu}_i) u^{\mu}_i \quad \text{and} \quad y = \sum_j (u^{\mu}_j, y) v^{\mu}_j.$$

We set $c_i = (q_i - q_i^{-1})^{-1}$, and we have

$$(1 \otimes E_i) \Theta_\mu - \Theta_\mu (1 \otimes E_i) = \sum_j u^{\mu}_j \otimes (E_i v^{\mu}_j - v^{\mu}_j E_i)$$

$$= c_i \sum_j u^{\mu}_j \otimes \left( \rho_j \left( v^{\mu}_j \right) K_i - L_i^{-1} \rho_j \left( v^{\mu}_j \right) \right) \quad \text{by Lemma 1.6}$$
$$= c_i \sum_{j,k} u^{\mu}_j \otimes \left[ \left( u^{\mu-a_i}_k \otimes v^{\mu-a_i}_j \right) v^{\mu-a_i}_j K_i - \left( u^{\mu-a_i}_k \otimes v^{\mu}_j \right) L_i^{-1} u^{\mu-a_i}_k \right]$$
$$= c_i \sum_{j,k} u^{\mu}_j \otimes \left[ \left( u^{\mu-a_i}_k \otimes E_i \otimes v^{\mu-a_i}_j \right) v^{\mu-a_i}_j K_i - \left( E_i u^{\mu-a_i}_k \otimes v^{\mu}_j \right) L_i^{-1} u^{\mu-a_i}_k \right] \quad \text{by Lemma 1.8}$$
$$= \sum_k \left( u^{\mu-a_i}_k \otimes E_i \otimes v^{\mu-a_i}_j \otimes K_i - E_i u^{\mu-a_i}_k \otimes L_i^{-1} v^{\mu-a_i}_j \right)$$
$$= \Theta_{\mu-a_i}(E_i \otimes K_i) - (E_i \otimes L_i^{-1}) \Theta_{\mu-a_i},$$

as expected because $\Psi(E_i \otimes 1) = E_i \otimes L_i^{-1}$ and $\Psi(K_i \otimes E_i) = 1 \otimes E_i$. A similar calculation show the fourth formula.

$\square$
Define, as in [Lus10, Chapter 4], the completion \( \mathcal{D}_q(g) \otimes \mathcal{D}_q(g) \) of \( \mathcal{D}_q(g) \otimes \mathcal{D}_q(g) \) with respect to the descending sequence of spaces

\[
(\mathcal{D}_q(g) \otimes \mathcal{D}_q(g))_N = \mathcal{D}_q(g) \otimes \sum_{ht(\mu) \geq N} \mathcal{D}_q(\mathcal{D}_q(g))_{q^0} \mathcal{D}_q(\mathcal{D}_q(g))_{q^0} + \sum_{ht(\mu) \geq N} \mathcal{D}_q(\mathcal{D}_q(g))_{q^0} \mathcal{D}_q(\mathcal{D}_q(g))_{q^0} \otimes \mathcal{D}_q(g).
\]

The morphism \( \Psi \) extends by continuity to \( \mathcal{D}_q(g) \otimes \mathcal{D}_q(g) \) and we consider the following element of \( \mathcal{D}_q(g) \otimes \mathcal{D}_q(g) \)

\[
\Theta = \sum_{\mu \in Q} \Theta_{\mu}.
\]

Then we can rewrite Proposition 1.14 as

\[
\Theta \Delta(u) = (\Psi \circ \Delta^o)(u) \Theta
\]

for any \( u \in \mathcal{D}_q(g) \).

We also have the analogue of [Jan96, Lemma 7.4].

**Lemma 1.15.** — For \( \mu \in Q, \mu \geq 0 \), we have

\[
(\Delta \otimes \text{id})(\Theta_{\mu}) = \sum_{0 \leq \nu \leq \mu} \left( \Theta_{\nu} \right)_{13}(1 \otimes K_{\nu} \otimes 1)(\Theta_{\mu - \nu})_{23},
\]

and

\[
(\text{id} \otimes \Delta)(\Theta_{\mu}) = \sum_{0 \leq \nu \leq \mu} \left( \Theta_{\nu} \right)_{13}(1 \otimes L_{-1 \nu} \otimes 1)(\Theta_{\mu - \nu})_{12}.
\]

**Proof.** — First, note that for any \( x \in \mathcal{D}_q(g)_{q^0}^{>0} \)

\[
\Delta(x) = \sum_{0 \leq \nu \leq \mu, i,j} \left( x, v^\nu_j v^\mu_j \right) u^\nu_i \otimes K_{\nu} u^\mu_j,
\]

and for any \( y \in \mathcal{D}_q(g)_{q^0}^{<0} \)

\[
\Delta(y) = \sum_{0 \leq \nu \leq \mu, i,j} \left( u^\nu_i u^\mu_j, y \right) L^{-1}_{-\nu} v^\mu_j \otimes v^\nu_i.
\]

Therefore

\[
(\Delta \otimes \text{id})(\Theta_{\mu}) = \sum_k \Delta(u^\mu_k) \otimes v^\mu_k
\]

\[
= \sum_{0 \leq \nu \leq \mu, i,j,k} \left( u^\nu_i v^\mu_j, u^\nu_i \otimes K_{\nu} u^\mu_j \otimes v^\mu_k \right)
\]

\[
= \sum_{0 \leq \nu \leq \mu, i,j} u^\nu_i \otimes K_{\nu} u^\mu_j \otimes v^\nu_j v^\mu_j
\]

\[
= \sum_{0 \leq \nu \leq \mu} \left( \Theta_{\nu} \right)_{13}(1 \otimes K_{\nu} \otimes 1)(\Theta_{\mu - \nu})_{23}.
\]

The proof of the other formula is similar. \( \square \)
We can translate this last lemma as equalities in $\mathcal{D}_q(\mathfrak{g}) \otimes \mathcal{D}_q(\mathfrak{g})$. Note that for any $x \in \mathcal{D}_q(\mathfrak{g})_\mu^0$ and $y \in \mathcal{D}_q(\mathfrak{g})_{-\mu}^0$, we have

\[
\begin{align*}
\Psi(x \otimes 1) &= x \otimes L^{-1}_\mu, & \Psi(1 \otimes x) &= K^{-1}_\mu \otimes x, \\
\Psi(y \otimes 1) &= y \otimes L_\mu, & \Psi(1 \otimes y) &= K_\mu \otimes y.
\end{align*}
\]

Therefore, we have

\[
(\Delta \otimes \text{id})(\Theta) = \sum_{\mu \geq 0} \sum_{\nu + \eta = \mu} (\Theta_{\eta})_{13} (1 \otimes K_\eta \otimes 1)(\Theta_{\nu})_{23}
\]

\[
= \sum_{\mu \geq 0} \sum_{\nu + \eta = \mu} \Psi_{23} (\Theta_{\eta})_{13} (\Theta_{\nu})_{23}
\]

\[
= \Psi_{23} (\Theta_{13}) \Theta_{23}.
\]

Similarly, we have

\[
(\text{id} \otimes \Delta)(\Theta) = \Psi_{12} (\Theta_{13}) \Theta_{12}.
\]

We now show that the element $\Theta$ is invertible. Set $\Gamma_{\mu} = (S \otimes \text{id})(\Theta_{\mu})(K_\mu \otimes 1)$ and $\Gamma = \sum_{\mu \geq 0} \Gamma_{\mu}$.

**Lemma 1.16.** — We have $\Gamma \Theta = 1 = \Theta \Gamma$ in $\mathcal{D}_q(\mathfrak{g}) \otimes \mathcal{D}_q(\mathfrak{g})$.

**Proof.** — We show that for all $\mu \geq 0$,

\[
\sum_{\lambda + \nu = \mu} \Gamma_{\lambda} \Theta_{\nu} = \delta_{\mu,0},
\]

and

\[
\sum_{\lambda + \nu = \mu} \Theta_{\lambda} \Gamma_{\nu} = \delta_{\mu,0}.
\]

We start with the first formula. We may and will suppose that $\mu > 0$. As

\[
\sum_{\lambda + \nu = \mu} \Gamma_{\lambda} \Theta_{\nu} = \sum_{\lambda + \nu = \mu} S(u^\lambda_i) K_\lambda u^\nu_j \otimes v^\lambda_i v^\nu_j
\]

is in $\mathcal{D}_q(\mathfrak{g}) \otimes \mathcal{D}_q(\mathfrak{g})_{-\mu}^0$, it suffices to show that applying $\text{id} \otimes (x, \cdot)$ gives zero, for all $x \in \mathcal{D}_q(\mathfrak{g})_{\mu}^0$. But

\[
\Delta(x) = \sum_{\lambda + \nu = \mu} D \left( x, u^\lambda_i v^\nu_j \right) u^\lambda_i \otimes K_\lambda u^\nu_j,
\]

so the antipode axiom gives

\[
0 = \varepsilon(x) = \sum_{\lambda + \nu = \mu} D \left( x, u^\lambda_i v^\nu_j \right) S(u^\lambda_i) K_\lambda u^\nu_j
\]

as desired.

For the second equality, we again apply $\text{id} \otimes (x, \cdot)$ to show that

\[
\sum_{\lambda + \nu = \mu} \Theta_{\lambda} \Gamma_{\nu} = \sum_{\lambda + \nu = \mu} u^\lambda_i S(u^\nu_j) K_\nu v^\lambda_i v^\nu_j = 0.
\]
The antipode axiom also gives
\[ 0 = \varepsilon(x) = \sum_{i,j} D\left(x, u_i^\lambda v_j^\mu\right) u_i^\lambda S(u_j^\mu) K_\lambda \]
which is, after multiplication by \( K_\mu \), the result expected. \( \square \)

We therefore have proven:

**Proposition 1.17.** — The element \( \Theta \in \mathcal{O}_q(\mathfrak{g}) \) is invertible and

- for all \( u \in \mathcal{O}_q(\mathfrak{g}) \) we have \( \Theta \Delta(u) = (\psi \circ \Delta^0)(u) \Theta \),
- \((\Delta \otimes \text{id}) (\Theta) = \Psi_{23}(\Theta_{13}) \Theta_{23} \),
- \((\text{id} \otimes \Delta)(\Theta) = \Psi_{12}(\Theta_{13}) \Theta_{12} \).

Finally, we give an explicit form of \( \Theta \) (compare with [CP94, 10.1.D])
\[
\Theta = \prod_{\alpha \in \Phi^+} \left( \sum_{n=0}^{+\infty} q_a^{\frac{\alpha}{\lambda} - \frac{1}{n}} [n]_{q_a} \left( q_a - q_{a_l}^{-1}\right)^n F_a(n) \otimes F_a(n) \right).
\]

2. Representation theory at \( q \) generic

We now turn to the representation theory of the quantum group \( \mathcal{O}_q(\mathfrak{g}) \), which is quite similar to the one of \( \mathcal{U}_q(\mathfrak{g}) \). We work over the field \( \mathbb{Q}(s) \).

2.1. Representations of \( \mathcal{O}_q(\mathfrak{g}) \). — We will consider the category \( \mathcal{C}_q \) of finite dimensional \( \mathcal{O}_q(\mathfrak{g}) \)-modules \( M \) such that
\[
M = \bigoplus_{(\lambda, \mu) \in P \times P} M_{(\lambda, \mu)},
\]
where \( M_{(\lambda, \mu)} \) denote the weight space of \( M \) associated to \((\lambda, \mu) \in P \times P\):
\[
M_{(\lambda, \mu)} = \{ n \in M \mid K_i \cdot m = q_i^{\lambda, \mu} m, \ L_i \cdot m = q_i^{\mu, \mu} m, \ \forall 1 \leq i \leq n \}.
\]

As \( \mathcal{O}_q(\mathfrak{g}) \) is a Hopf algebra, \( \mathcal{C}_q \) is a monoidal rigid abelian category. For \((\lambda, \mu) \in P \times P \) and \((\lambda', \mu') \in P \times P \), we write \((\lambda, \mu) \leq (\lambda', \mu')\) if \((\lambda' - \lambda, \mu' - \mu) = \sum_{a \in \Lambda} n_a (a, a)\) with \( n_a \in \mathbb{N} \).

**Proposition 2.1.** — A simple module \( M \) in \( \mathcal{C}_q \) is a highest weight module.

**Proof.** — Let \( M \) be a simple module in \( \mathcal{C}_q \). Then, there exists a weight \((\lambda, \mu)\) of \( M \) such that for all other weight \((\lambda', \mu')\) of \( M \), we have \((\lambda, \mu) \neq (\lambda', \mu')\). Such a weight exists because \( M \) is finite dimensional. Pick a non-zero \( v \in M_{(\lambda, \mu)} \). As, by choice of \((\lambda, \mu)\), \((\lambda + a_i, \mu + a_i)\) is not a weight of \( M \) for any \( i \), we have \( E_i m = 0 \) for all \( i \). Hence \( v \) is a highest weight vector.

Consider now the \( \mathcal{O}_q(\mathfrak{g}) \)-module of \( M \) generated by \( v \). As \( M \) is simple and \( v \neq 0 \), it is the entire module \( M \): \( M \) is a highest weight module. \( \square \)

**Proposition 2.2.** — Any highest weight \((\lambda, \mu)\) of a module in \( \mathcal{C}_q \) satisfy \( \lambda + \mu \in 2P^+ \).

**Proof.** — Let \( M \) be a module in \( \mathcal{C}_q \) and \( m \in M \) a highest weight vector of weight \((\lambda, \mu)\). Let \( 1 \leq i \leq n \) and consider the family \( (F_i^{(k)} m)_{k \in \mathbb{N}} \) of vectors in \( M \). The vector \( F_i^{(k)} m \) being of weight \((\lambda, \mu) - k(a, a_i)\) and \( M \) being finite dimensional, there exists \( k \in \mathbb{N} \) such that \( F_i^{(k)} m \neq 0 \) and \( F_i^{(k+1)} m = 0 \). Let \( k \) be the smallest of these integers. As
\[
[E, F_i^{(k+1)}] = F_i^{(k)} q_i^{-k} K_i - q_i^{k} L_i^{-1},
\]

we have \( 0 = [E, F^{(k+1)}] m = \frac{q^{-k+\langle \lambda, \alpha_i^\vee \rangle}}{q - q_i} F^{(k)} m \). Therefore \( \langle \lambda + \mu, \alpha_i^\vee \rangle = 2k \).

For any \( \lambda \in P \), there exists a one-dimensional \( \mathcal{O}_q(g) \)-module with unique (hence highest) weight \( (\lambda, -\lambda) \), which we denote by \( L(\lambda; -\lambda) \). The elements \( E \) and \( F \) necessarily acts by 0 and the action of \( K_i \) (resp. \( L_i \)) is multiplication by \( q^{\langle \lambda, a_i \rangle} \) (resp. \( q^{-\langle \lambda, a_i \rangle} \)).

We denote by \( \tilde{P} \) the subset of \( P \times P \) such that the sum of the two components is in \( 2P \). These are precisely the weights which appear as weights of objects of the category \( \mathcal{C}_q \).

**Proposition 2.3.** — For any \( (\lambda, \mu) \in \tilde{P} \), there exists a simple module of highest weight \( (\lambda, \mu) \).

**Proof.** — Using the classification of \( \mathcal{U}_q(g) \)-modules (see [CP94 Proposition 10.1.1]), there exists a simple \( \mathcal{O}_q(g) \)-module of highest weight \( (\frac{\lambda + \mu}{2}, \frac{\lambda + \mu}{2}) \). Tensoring this module with \( L(\frac{\lambda - \mu}{2}, -\frac{\lambda - \mu}{2}) \), we obtain a simple module in \( \mathcal{C}_q \) of highest weight \( (\lambda, \mu) \).

Therefore, simple objects in \( \mathcal{C}_q \) are classified by \( (\lambda, \mu) \in \tilde{P} \) such that \( \lambda + \mu \in 2P^+ \). We denote \( \tilde{P}^+ \) this set of weights and by \( L(\lambda, \mu) \) the simple module of highest weight \( (\lambda, \mu) \). Note that we also have a construction of simple modules “à la Verma”.

**Proposition 2.4.** — The category \( \mathcal{C}_q \) is semisimple.

**Proof.** — It suffices to show that there are no extension \( 0 \rightarrow L \rightarrow M \rightarrow N \rightarrow 0 \) of objects in \( \mathcal{C}_q \) with \( M \) indecomposable and \( L, N \) non-trivial. If such an extension exists, for \( 1 \leq i \leq n \) the action of \( z_i \) on \( M \) has a unique eigenvalue. Therefore, for any weight \( (\lambda, \mu) \) of \( M \), the value \( \lambda - \mu \) does not depend on the weight and is in \( 2P \). We tensorize the exact sequence by the invertible object \( X = L(\frac{\mu - \lambda}{2}, -\frac{\mu - \lambda}{2}) \) in order to obtain an exact sequence of \( \mathcal{U}_q(g) \)-modules. As the category of finite dimensional \( \mathcal{U}_q(g) \)-modules is split, \( M \otimes X \simeq (L \otimes X) \oplus (N \otimes X) \). Therefore \( M \cong L \oplus M \), contrary to our assumption.

There exists a faithful \( P \)-grading on the category \( \mathcal{C}_q \) given by the action of the central elements \( (z_i)_{1 \leq i \leq n} \)

\[
\mathcal{C}_q = \bigoplus_{v \in P} \mathcal{C}_{q,v}
\]

where \( \mathcal{C}_{q,v} \) is additively generated by simple objects \( L(\lambda, \mu) \) with \( \lambda - \mu = 2v \), i.e. the simple objects on which the action of the central elements \( (z_i)_{1 \leq i \leq n} \) acts by \( 2v \). Each component \( \mathcal{C}_{q,v} \) is equivalent to the category of finite dimensional \( \mathcal{U}_q(g) \)-modules: it is clear for the trivial component \( \mathcal{C}_{q,0} \) and tensoring by \( L(v, -v) \) gives an equivalence between \( \mathcal{C}_{q,0} \) and \( \mathcal{C}_{q,v} \).

**2.2. Character formula.** — We now write a character formula, which we obtain easily using Weyl character formula (see [Hum78 24.3]). We define an action of the Weyl group \( W \) on \( \tilde{P} \) as follows

\[
s_i(\lambda, \mu) = (\lambda, \mu) - \frac{1}{2}(\lambda + \mu, \alpha_i^\vee)(a_i, a_i),
\]

for any \( 1 \leq i \leq n \). It is easily shown, by induction on the length of \( w \in W \) that

\[
w(\lambda, \mu) = \left( w \left( \frac{\lambda + \mu}{2} \right) + \frac{\lambda - \mu}{2}, w \left( \frac{\lambda + \mu}{2} \right) - \frac{\lambda - \mu}{2} \right).
\]
We denote by $e^{(\lambda, \mu)} \in \mathbb{Z}[P \times P]$ the element of the group ring of $P \times P$ over $\mathbb{Z}$ corresponding to $(\lambda, \mu)$. The character of a module $M$ in $\mathcal{C}_q$ is
\[ \chi_M = \sum_{(\lambda, \mu) \in P \times P} \dim(M_{(\lambda, \mu)}) e^{(\lambda, \mu)}. \]
Almost every term of the sum are zero and the support of $\chi_M$ is included in $\hat{P}$.

The usual Weyl character formula gives the character of all simple modules in $\mathcal{C}_q$ of the form $L(\lambda, \lambda)$ with $\lambda \in P^+$:
\[ \chi(\lambda, \lambda) = \sum_{w \in W} (-1)^{(l(w) - l(w')/2)} e^{(w(\lambda + \mu), w(\lambda + \mu))} e^{(\lambda, \mu)}, \]
As, for $(\lambda, \mu) \in \hat{P}$, we have an isomorphism in $\mathcal{C}_q$
\[ L(\lambda, \mu) \simeq L \left( \frac{\lambda + \mu}{2}, \frac{\lambda + \mu}{2} \right) \otimes L \left( \frac{\lambda - \mu}{2}, -\frac{\lambda - \mu}{2} \right), \]
the character of $L(\lambda, \mu)$ is
\[ \chi(\lambda, \mu) = \frac{\sum_{w \in W} (-1)^{(l(w) - l(w'))/2} e^{(w(\lambda + \mu + \rho), w(\lambda + \mu + \rho))}}}{\sum_{w \in W} (-1)^{(l(w) - l(w'))/2} e^{(w(\rho), w(\rho))}} \]
which is therefore equal to
\[ \chi(\lambda, \mu) = \frac{\sum_{w \in W} (-1)^{(l(w) - l(w'))/2} e^{(w(\lambda + \rho, \mu + \rho))}}}{\sum_{w \in W} (-1)^{(l(w) - l(w'))/2} e^{(w(\rho, \rho))}}. \]

We rewrite this formula by introducing the dot action $w \cdot (\lambda, \mu) = w(\lambda + \rho, \mu + \rho) - (\rho, \rho)$ which stabilizes $P \times P$:
\[ \chi(\lambda, \mu) = \frac{\sum_{w \in W} (-1)^{(l(w) - l(w'))/2} e^{(w(\lambda + \rho, \mu + \rho))}}}{\sum_{w \in W} (-1)^{(l(w) - l(w'))/2} e^{(w(\rho, \rho))}}. \]

2.3. Braiding. — Using the quasi-$R$-matrix of section 1.7 we endow the tensor category $\mathcal{C}_q$ with a braiding.

First, as any element of $\mathcal{C}_q$ has a finite number of weights, we see that for $N$ sufficiently large and any $\mu \in Q$, $\mu \geq 0$ and $\text{ht}(\mu) \geq N$, the element $\Theta_\mu$ of section 1.7 acts by 0 on any tensor product of two elements of $\mathcal{C}_q$. Therefore, for any $M$ and $M'$ in $\mathcal{C}_q$, the action of $\Theta$ defines a linear map
\[ \Theta_{M, M'} : M \otimes M' \to M \otimes M'. \]
Note that this map is not $\mathcal{O}(\mathfrak{g})$-linear but satisfies for any $u \in \mathcal{O}(\mathfrak{g})$
\[ \Theta_{M, M'} \circ \Delta(u) = (\Psi \circ \Delta^\mathfrak{g})(u) \circ \Theta_{M, M'}, \]
as linear endomorphisms of $M \otimes M'$. This follows immediately from Proposition 1.14.

To construct the braiding, we need one more ingredient. For $M$ and $M'$ two objects of $\mathcal{C}_q$, we introduce a linear map $f_{M, M'} : M \otimes M' \to M \otimes M'$ defined on weight vectors $m \in M_{\lambda, \mu}$ and $m' \in M'_{\lambda', \mu'}$ by
\[ f_{M, M'}(m \otimes m') = q^{(\lambda, \mu)} m \otimes m', \]
where we write $q^r = s^{r/s}$ for any $r \in \mathbb{Z}$ (recall that $s$ is a $L$-th root of $q$, see Section 1.1).

Lemma 2.5. — For any $u \in \mathcal{O}(\mathfrak{g}) \otimes \mathcal{O}(\mathfrak{g})$, we have the following equality as linear endomorphisms of $M \otimes M'$
\[ u \circ f_{M, M'} = f_{M, M'} \circ \Psi(u). \]
Proof. — It suffices to show it on the generators of \( \mathcal{O}_q(\mathfrak{g}) \otimes \mathcal{O}_q(\mathfrak{g}) \). It is trivial for \( K_i \otimes 1 \), \( L_i \otimes 1 \), \( 1 \otimes K_i \) and \( 1 \otimes L_i \). We now verify it for \( E_i \otimes 1 \). On the one hand,

\[
(f_{M,M'} \circ (E_i \otimes L_i^{-1}))|_{M_{i,a} \otimes M'_{i,a'}} = \delta^{(\lambda_i, \mu_i) - (\lambda_{i'}, \mu_{i'})}(E_i \otimes 1)|_{M_{i,a} \otimes M'_{i,a'}}.
\]

On the other hand,

\[
[(E_i \otimes 1) \circ f_{M,M'}]|_{M_{i,a} \otimes M'_{i,a'}} = \delta^{(\lambda, \mu)}(E_i \otimes 1)|_{M_{i,a} \otimes M'_{i,a'}},
\]

which concludes the proof for \( E_i \otimes 1 \). The other cases are similar.

Denote by \( \tau \) the twist of vector spaces and define

\[
c_{M,M'} = \tau \circ f_{M,M'} \circ \Theta_{M,M'}.
\]

It is then a morphism in \( \mathcal{C}_q \) between \( M \otimes M' \) and \( M' \otimes M \). Indeed, for any \( u \in \mathcal{O}_q(\mathfrak{g}) \) we have

\[
c_{M,M'} \circ u|_{M \otimes M'} = \tau \circ f_{M,M'} \circ \Theta_{M,M'} \circ \Delta(u)|_{M \otimes M'} = \tau \circ f_{M,M'} \circ \Delta^\text{op}(u)|_{M \otimes M'} = \Delta^\text{op}(u)|_{M' \otimes M} \circ f_{M,M'} \circ \Theta_{M,M'} = \Delta(u)|_{M' \otimes M} \circ c_{M,M'} = u|_{M' \otimes M} \circ c_{M,M'}.
\]

Proposition 2.6. — The morphisms \( c \) defined above endow \( \mathcal{C}_q \) with a braiding: the hexagon axioms are satisfied.

Proof. — We check that \( c_{M,M' \otimes M''} = (\text{id}_{M' \otimes M''} \circ c_{M,M'}) \circ (c_{M,M' \otimes M''} \otimes \text{id}_{M''}) \). It follows from the following calculations, where we denote by \( \tau_{1,23} : M \otimes (M' \otimes M'') \to (M' \otimes M'') \otimes M \) the twist, which is equal to \( \tau_{23} \circ \tau_{12} \):

\[
c_{M,M' \otimes M''} = \tau_{1,23} \circ f_{M,M' \otimes M''} \circ \Theta_{M,M' \otimes M''} = \tau_{23} \circ \tau_{12} \circ (f_{M,M''})_{13} \circ \Theta(\Psi_{12})|_{M \otimes M' \otimes M''} = \tau_{23} \circ \tau_{12} \circ (f_{M,M''})_{13} \circ \Theta_{12}|_{M \otimes M' \otimes M''} = \tau_{23} \circ \tau_{12} \circ (f_{M,M''})_{13} \circ \Theta_{12}|_{M \otimes M' \otimes M''} = \tau_{23} \circ \tau_{12} \circ (f_{M,M''})_{13} \circ \Theta_{12}|_{M \otimes M' \otimes M''} = \tau_{23} \circ \tau_{12} \circ (f_{M,M''})_{13} \circ \Theta_{12}|_{M \otimes M' \otimes M''} = \text{id}_{M' \otimes M''} \circ c_{M,M''} \circ \text{id}_{M''} = c_{M,M''} \circ \text{id}_{M' \otimes M''}.
\]

The other hexagon axiom is shown similarly.

2.4. Duality and pivotal structure. — The algebra \( \mathcal{O}_q(\mathfrak{g}) \) being a Hopf algebra, for any \( \mathcal{O}_q(\mathfrak{g}) \)-module \( M \) in \( \mathcal{C}_q \), the space of linear forms has naturally a structure of left (resp. right) dual denoted by \( M^* \) (resp. \( M^* \)), where the action of \( u \in \mathcal{O}_q(\mathfrak{g}) \) on \( \varphi \in M^* \) (resp. \( \varphi \in M^* \)) is given by

\[
(u \cdot \varphi)(m) = \varphi(S(u) \cdot m) \quad \text{(resp. } (u \cdot \varphi)(m) = \varphi(S^{-1}(u) \cdot m)\text{)}.
\]

Let \( (\lambda, \mu) \in \tilde{P}^+ \). The simple module \( L(\lambda, \mu) \) is isomorphic to \( L(\lambda + \mu, \lambda + \mu) \otimes L(\lambda - \mu, \lambda - \mu) \) and

\[
L(\lambda, \mu)^* \simeq L\left(\frac{\lambda - \mu}{2}, \frac{\lambda - \mu}{2}\right)^* \otimes L\left(\frac{\lambda + \mu}{2}, \frac{\lambda + \mu}{2}\right)^*.
\]
But the left dual of a simple \( \mathcal{U}_q(g) \)-module \( L(\kappa, \kappa) \) is isomorphic to \( L(-w_0(\kappa), -w_0(\kappa)) \) and the left dual of the invertible module \( L(\kappa, -\kappa) \) is clearly isomorphic to \( L(-\kappa, \kappa) \). Consequently,

\[
L(\lambda, \mu)^* \cong L\left(\frac{\mu - \lambda}{2}, -\frac{\mu - \lambda}{2}\right) \otimes L\left(-w_0\left(\frac{\lambda + \mu}{2}\right), -w_0\left(\frac{\lambda + \mu}{2}\right)\right) \cong L(-w_0(\lambda, \mu)).
\]

Similarly \( *L(\lambda, \mu) \cong L(-w_0(\lambda, \mu)) \), which also follows from the pivotal structure given below.

As for any \( u \in \mathcal{D}_q(g) \) we have \( S^2(u) = K_{2\rho} u K_{2\rho}^{-1} \), we have for any \( \lambda \in Q \) a pivotal structure given by

\[
a_{\lambda, M} : \begin{cases} 
M & \mapsto M^{**} \\
m & \mapsto \varphi((L, K_{2\rho - \lambda}) \cdot m)
\end{cases}
\]

We will consider only the pivotal structure given by \( \lambda = 2\rho \), i.e. we choose \( L_{2\rho} \) as pivotal element. This pivotal structure allows us to compute left and right quantum dimensions of modules. It follows from the Weyl character formula that

\[
dim^+(L(\lambda, \mu)) = \frac{\sum_{\mu \in W(-1)^l(\mu)^{-2}(\mu \cdot \lambda, \mu)} q^{(2 \rho, w(\mu, \lambda))_2}}{\sum_{\mu \in W(-1)^l(\mu)^{-2}(\mu \cdot 0, \mu))_2}}
\]

and

\[
dim^-(L(\lambda, \mu)) = \frac{\sum_{\mu \in W(-1)^l(\mu)^{-2}(\mu \cdot (2 \rho, w(\mu, 0))_2}}{\sum_{\mu \in W(-1)^l(\mu)^{-2}(\mu \cdot (2 \rho, w(0))_2}}.
\]

As the actions of \( L_{2\rho} \) and \( K_{2\rho} \) coincide on any \( \mathcal{U}_q(g) \)-module, the quantum dimensions of \( L_q(\kappa, \kappa) \) viewed as a \( \mathcal{D}_q(g) \)-module coincide with the quantum dimensions of \( L_q(\kappa, \kappa) \) viewed as a \( \mathcal{U}_q(g) \)-module.

### 3. Specialization at a root of unity and tilting modules

The goal to this section is to construct a fusion category using the representations of \( \mathcal{D}_q(g) \). But the category \( \mathcal{C}_q \) has an infinite number of simple objects. We adapt the construction of the fusion categories attached to quantum groups at roots of unity to \( \mathcal{D}_q(g) \). Recall the notation \( \mathfrak{C} = \mathbb{Z}[s, s^{-1}] \).

#### 3.1. Lusztig’s integral form.

We introduce a \( \mathfrak{C} \)-subalgebra of \( \mathcal{D}_q(g) \) which we will use to specialize \( \mathcal{D}_q(g) \) at a root of unity. Consider the following elements of \( \mathcal{D}_q(g) \):

\[
\begin{align*}
[K_i; c t] &= \prod_{r=1}^{t} q_i^{c-r+1} K_i - q_i^{-c+r-1} K_i^{-1}, \\
[L_i; c t] &= \prod_{r=1}^{t} q_i^{c-r+1} L_i - q_i^{-c+r-1} L_i^{-1}, \\
[z_i; c t] &= \prod_{r=1}^{t} q_i^{c-r+1} z_i - q_i^{-c+r-1} z_i^{-1}
\end{align*}
\]

for \( 1 \leq i \leq n, c \in \mathbb{Z} \) and \( t \in \mathbb{N} \).

We define \( \mathcal{D}_q^{\text{res}}(g) \) as the \( \mathfrak{C} \)-subalgebra generated by \( E_i^{(r)}, F_i^{(r)}, K_i, L_i; [K_i; c t], [L_i; c t], [z_i; c t], [K_i; c L_i t] \), for \( 1 \leq i \leq n, c \in \mathbb{Z} \) and \( t \in \mathbb{N} \). The coproduct, the counit and the antipode of \( \mathcal{D}_q(g) \) restrict to \( \mathcal{D}_q^{\text{res}}(g) \) and endow \( \mathcal{D}_q^{\text{res}}(g) \) with a structure of a Hopf algebra.
The quotient of $\mathcal{G}_q^\text{res}(g)$ by the Hopf ideal generated by $z_i - 1, [z_i; \ c \ t \ i \ \ t \ -1 \ i \ [K_i; c; L_i \ t \ i \ t \ -1 \ i \]$ and $[K_i; c; L_i \ t \ i \ t \ -1 \ i \ [K_i; c; L_i \ t \ i \ t \ -1 \ i \$, for $1 \leq i \leq n$ is the usual Lusztig’s integral form of $\mathcal{U}_q(g)$ (see [CP94] Section 9.3).

The element of the form $[K_i; c; L_i \ t \ i \ t \ -1 \ i \]$ appears naturally in the following identity, proved by induction

$$E^{(p)}_i F^{(r)}_i = \sum_{t=0}^{\min(p, r)} F^{(r-1)}_i [K_i; 2 t - r - p; L_i \ t \ i \ t \ -1 \ i \],$$

for any $1 \leq i \leq n, r, s \in \mathbb{N}$.

The following formulas for the coproduct will be useful.

**Proposition 3.1.** Let $1 \leq i \leq n$ and $t \in \mathbb{N}$. Then

1. $\Delta \left( [K_i; 0 \ t \ i \ t \ -1 \ i \right) = \sum_{r=0}^{t} [K_i; 0 \ t \ r \ i \ r \ i \ t \ -1 \ i \] K_i^{r-1} \otimes [K_i; 0 \ r \ i \ r \ i \ t \ -1 \ i \] K_i^{l-1},$
2. $\Delta \left( [L_i; 0 \ t \ i \ t \ -1 \ i \right) = \sum_{r=0}^{t} [L_i; 0 \ t \ r \ i \ r \ i \ t \ -1 \ i \] L_i^{r-1} \otimes [L_i; 0 \ r \ i \ r \ i \ t \ -1 \ i \] L_i^{l-1},$
3. $\Delta \left( [K_i; 0; L_i \ t \ i \ t \ -1 \ i \right) = \sum_{r=0}^{t} [K_i; 0; L_i \ t \ r \ i \ r \ i \ t \ -1 \ i \] L_i^{r-1} \otimes [K_i; 0; L_i \ r \ i \ r \ i \ t \ -1 \ i \] K_i^{l-1},$
4. $\Delta \left( [z_i; 0 \ t \ i \ t \ -1 \ i \right) = \sum_{r=0}^{t} [z_i; 0 \ t \ r \ i \ r \ i \ t \ -1 \ i \] z_i^{r-1} \otimes [z_i; 0 \ r \ i \ r \ i \ t \ -1 \ i \] z_i^{l-1}.$

We denote by $\mathcal{G}_q^\text{res}(g)^{>0}$ (resp. $\mathcal{G}_q^\text{res}(g)^{0}$, resp. $\mathcal{G}_q^\text{res}(g)^{<0}$) the intersection of $\mathcal{G}_q^\text{res}(g)$ with $\mathcal{G}_q(g)^{>0}$ (resp. $\mathcal{G}_q(g)^{0}$, resp. $\mathcal{G}_q(g)^{<0}$).

It is not hard to show that for any $1 \leq i \leq n$, the automorphism $T_i$ restricts to $\mathcal{G}_q^\text{res}(g)$. As in Section 1.6, we have:

**Proposition 3.2 ([Lus90] Theorem 6.7]).** The elements

$$\prod_{\alpha \in \Phi_+} E_{n_\alpha}^{(n_\alpha)} , \ n_\alpha \in \mathbb{N}$$

form an $\mathcal{A}$-basis of $\mathcal{G}_q^\text{res}(g)^{>0}$.

The elements

$$\prod_{\alpha \in \Phi_+} F_{n_\alpha}^{(n_\alpha)} , \ n_\alpha \in \mathbb{N}$$

form an $\mathcal{A}$-basis of $\mathcal{G}_q^\text{res}(g)^{<0}$.

Note that the quasi-$R$-matrix at the end of Section 1.7 belongs in fact in $\mathcal{G}_q^\text{res}(g)$ and the formula for its inverse show that it also belongs to $\mathcal{G}_q^\text{res}(g)$. We still denote by $\Theta$ this element. Moreover, the algebra endomorphism $\Psi$ of $\mathcal{G}_q(g) \otimes \mathcal{G}_q(g)$ restricts to an algebra endomorphism of $\mathcal{G}_q^\text{res}(g) \otimes \mathcal{G}_q^\text{res}(g)$, which we still denote by $\Psi$. Therefore, we still have the relations

$$\Theta \Delta(u) = (\Psi \circ \Delta^\text{op})(u) \Theta, \ (\text{id} \otimes \Delta)(\Theta) = \Psi_{12}(\Theta_{13}) \Theta_{12}, \text{ and } (\Delta \otimes \text{id})(\Theta) = \Psi_{23}(\Theta_{13}) \Theta_{23}.$$
3.2. Specialization at a root of unity. — Let $\xi \in \mathbb{C}$ be a root of unity of order $l$. Set $l' = l$ if $l$ is odd and $l' = \frac{l}{2}$ if $l$ is even so that $l'$ is the order of $\xi^2$. We fix $\xi^{1/l}$ an $L$-th root of $\xi$ and consider the morphism of rings

$$
\sigma : s \rightarrow \xi^{1/l}.
$$

The specialization of $D_q(g)$ at $\xi$ is by definition the algebra $D_\xi(g) = D_q^{\text{res}}(g) \otimes_{\sigma} \mathbb{C}$. Introduce the integers $l_i$ as the order of $\xi_i = \xi^{(a_i,a_i)}$ and set $l'_i = l_i$ if $l_i$ is odd and $l'_i = \frac{l_i}{2}$ if $l_i$ is even so that $l'_i$ is the order of $\xi_i^2$.

The algebra $D_\xi(g)$ is generated by elements of the form

$$
E_{i}^{(r)}, F_{i}^{(r)}, K_{i}^{\pm 1}, L_{i}^{\pm 1}, \left[ K_{i}; c \right] \left[ L_{i}; t \right], \left[ K_{i}; c; L_{i} \right] \text{ and } \left[ z_{i}; c \right],
$$

for $1 \leq i \leq n$, $r, t \in \mathbb{N}$ and $c \in \mathbb{Z}$ given by the images in $D_\xi(g)$ of the corresponding elements of $D_q^{\text{res}}(g)$. There exist some relations in $D_\xi(g)$ related to the order of the root of the $\xi_i$'s as

$$
E_{i}^{l_i} = 0, F_{i}^{l_i} = 0, K_{i}^{2l_i} = 1, L_{i}^{2l_i} = 1, K_{i} = L_{i}.
$$

We denote by $\Theta_\xi$ the specialization of $\Theta$. It is still an invertible element of some completion of $D_\xi(g) \otimes D_\xi(g)$, and we have an algebra endomorphism $\Psi_\xi$ which is the specialization of $\Psi$. They satisfy the usual relations

$$
\Theta_\xi \Delta(u) = \left( \Psi_\xi \circ \Delta^{\text{op}} \right)(u) \Theta_\xi, \quad (\text{id} \otimes \Delta)(\Theta_\xi) = (\Psi_\xi)_{12}(\Theta_\xi)_{13}(\Theta_\xi)_{12},
$$

and $(\Delta \otimes \text{id})(\Theta_\xi) = (\Psi_\xi)_{23}(\Theta_\xi)_{13}(\Theta_\xi)_{23}$.

3.3. Representations at a root of unity. — The representation theory of $D_\xi(g)$, as well the one of $D_\xi(g)$, is more involved. As explained in [CP94: 11.2.A], defining the weight space of weight $(\lambda, \mu)$ of a $D_\xi^{\text{res}}(g)$-module $M$ as

$$
M_{\lambda, \mu} = \{ m \in M \mid K_i m = \xi^{(\lambda, a_i)} m, L_i m = \xi^{(\mu, a_i)} m, \forall 1 \leq i \leq n \}
$$

is rather unsatisfactory: one can not distinguish the weight $(\lambda, \mu)$ form the weight $(\lambda + l_i\sigma_i, \mu)$ for example.

The weight space of weight $(\lambda, \mu)$ of $M$ is then defined as

$$
M_{\lambda, \mu} = \{ m \in M \mid K_i m = \xi^{(\lambda, a_i)} m, L_i m = \xi^{(\mu, a_i)} m, [K_i; 0] m = \left[ (\lambda, a_i) \right]_{\xi_i}^{l_i}, [L_i; 0] m = \left[ (\mu, a_i') \right]_{\xi_i}^{l_i'}, \forall 1 \leq i \leq n \}.
$$

**Proposition 3.3.** — Let $(\lambda, \mu)$ and $(\lambda', \mu')$ two weights of a module $M$. Then $M_{\lambda, \mu} = M_{\lambda', \mu'}$ if and only if $(\lambda, \mu) = (\lambda', \mu')$.

**Proof.** — We show that for $\zeta$ a root of unity of order $d$ and with $d' = d$ if $d$ is odd, $d' = \frac{d}{2}$ if $d$ is even, and $r \in \mathbb{Z}$, we can recover $r$ knowing only $\left[ \frac{r}{d'} \right]_{\zeta}$ and $\zeta^r$.

**Lemma 3.4.** — Let $a, b \in \mathbb{N}$ with $a \geq b$. Let $a = a_1 d' + a_0$ and $b = b_1 d' + b_0$ with $0 \leq a_0, b_0 < d'$. Then

$$
\left[ \begin{array}{c} a \\ b \end{array} \right]_{\zeta} = (-1)^{(d'+1)(a_1+1)b_1} \left( \zeta^{d'} \right)^{(a_1+1)b_1 + a_1 b_0 + a_0 b_1} \left( \begin{array}{c} a_1 \\ b_1 \end{array} \right) \left( \begin{array}{c} a_0 \\ b_0 \end{array} \right).$$
Proof. — We start with the following equality, valid for any \( m \in \mathbb{N} \) and \( X \) an indeterminate
\[
\prod_{k=0}^{m-1} (1 + \zeta^{2k} X) = \sum_{k=0}^{m} \zeta^{k(m-1)} \binom{m}{k} X^k.
\]

As \( \{\zeta^{-2k} | 0 \leq k < d'\} \) is the set of \( d' \)th-roots of 1 and
\[
\prod_{k=0}^{d'-1} (1 + \zeta^{2k} X) = \zeta^{d'(d'-1)} \prod_{k=0}^{d'-1} (X + \zeta^{-2k})
\]
we have
\[
\prod_{k=0}^{d'-1} (1 + \zeta^{2k} X) = \zeta^{d'(d'-1)}(X^{-d'} - (-1)^{d'}) \equiv \zeta^{d'(d'+1)}(X^{d'} + (-1)^{d'+1}).
\]

On the one hand we have
\[
\prod_{k=0}^{a-1} (1 + \zeta^{2k} X) = \sum_{k=0}^{a} \zeta^{k(r-1)} \binom{a}{k} X^k,
\]
and on the other hand
\[
\prod_{k=0}^{a-1} (1 + \zeta^{2k} X) = \left(\zeta^{d'(d'+1)}(X^{d'} + (-1)^{d'+1})\right)^{a_1} \left(\prod_{k=0}^{a_0-1} (1 + \zeta^{2k} X)\right)
\]
\[
= \zeta^{d'(d'+1)a_1} \left(\sum_{k=0}^{a_0} \binom{a}{k} (-1)^{(d'+1)(a_1-k)} X^{kd'}\right) \left(\sum_{k=0}^{a_0} \zeta^{k(a_1-k)} \binom{a_0}{k} X^k\right).
\]

Comparing the coefficient of \( X^b \) gives us
\[
\zeta^{b(a-1)} \binom{a_1}{b_1} = \zeta^{d'(d'+1)a_1 + b_1(a_0-1) - (d'+1)(a_1-b_1)} \binom{a_1}{b_1} \binom{a_0}{b_0},
\]
which, using the fact that \( \zeta^{d'(d'+1)} = (-1)^{d'+1} \), leads to the desired formula.

Therefore, for \( r \in \mathbb{N} \), we have
\[
sqrts\[\frac{d'}{r}\zeta = \begin{cases} \frac{r_1}{1} & \text{if } d' = d, \\ (-1)^{r_0+1} r_1 & \text{if } d' = \frac{d}{2} \text{ and } d' \text{ odd}, \\ (-1)^{r_0} r_1 & \text{if } d' = \frac{d}{2} \text{ and } d' \text{ even}. \end{cases}\]
\]
Using \( \left[-\frac{r}{d'}\right]_\zeta = (-1)^d \left[\frac{r + d' - 1}{d'}\right]_\zeta \), we check that this is still valid for \( r \in \mathbb{Z} \).

We write \( r = r_1 d' + r_0 \) with \( 0 \leq r_0 < d' \). Let \( 0 \leq r' < d \) be the unique integer such that \( \zeta^r = \zeta^{r'} \).

First, we suppose \( d' = d \), hence \( d' \) is odd. Lemma 3.4 gives \( \left[\frac{r}{d'}\right]_\zeta = r_1 \) and we have
\[
r = \left[\frac{r}{d'}\right]_\zeta d' + r'.
\]

Now, we suppose that \( d \) is even. Let \( r'' = r' \) if \( 0 \leq r' < d' \) and \( r'' = r' - d' \) otherwise.

We suppose that \( d' = \frac{d}{2} \) is odd. Lemma 3.4 gives \( \left[\frac{r}{d'}\right]_\zeta = (-1)^{r_0+1} r_1 \). If \( r'' = r' \) then
\[
r = (-1)^{r''+1} \left[\frac{r}{d'}\right]_\zeta + r'', \text{ and if } r'' \neq r' \text{ then } r = (-1)^{r''} \left[\frac{r}{d'}\right]_\zeta + r''.
\]

Finally, if we suppose that $d' = \frac{d}{2}$ is even, Lemma 3.4 gives $\left[ \frac{r}{d'} \right]_\xi = (-1)^r r_l$ and $r = (-1)^r \left[ \frac{r}{d'} \right]_\xi + r''$.

Therefore, if for all $1 \leq i \leq n$, $\xi_i^{(\lambda, \alpha_i)} = \xi_i^{(\lambda', \alpha_i)}$ and $\left[ \langle \lambda, \alpha_i \rangle \right]_{l_i^j} \left[ \langle \lambda', \alpha_i \rangle \right]_{l_i^j} = \left[ \langle \lambda', \alpha_i \rangle \right]_{l_i^j}$, we have $\langle \lambda, \alpha_i \rangle = \langle \lambda', \alpha_i \rangle$ for all $1 \leq i \leq n$ and hence $\lambda = \lambda'$. Similarly $\mu = \mu'$.

The formula for the coproduct given in the Proposition 3.1 shows that the tensor product of two weight vectors of weight $(\lambda, \mu)$ and $(\lambda', \mu')$ is again a weight vector, of weight $(\lambda + \lambda', \mu + \mu')$.

We consider the category $\mathcal{C}_\xi$ of finite dimensional $\mathcal{D}_\xi(g)$-modules $M$ such that

$$M = \bigoplus_{(\lambda, \mu) \in P \times P} M_{\lambda, \mu}.$$

As in the generic case we have $E_i^{(r)} \cdot M_{\lambda, \mu} \subseteq M_{\lambda + r_i \alpha_i, \mu + r_i \alpha_i}$ and $F_i^{(r)} \cdot M_{\lambda, \mu} \subseteq M_{\lambda - r_i \alpha_i, \mu - r_i \alpha_i}$.

Contrary to the generic case, it may happen that $\lambda + \mu \notin 2P$, for example if one of the $l_i$’s is odd.

One way to construct $\mathcal{D}_\xi(g)$-modules is specialization. Let $(\lambda, \mu) \in 2P$. We have defined a simple highest weight $\mathcal{D}_q(g)$-module $L(\lambda, \mu)$ and we consider a sub-$\mathcal{D}_q^\text{res}(g)$-module $L^\text{res}(\lambda, \mu)$ generated by a chosen highest weight vector. Define the Weyl module by

$$W_\xi(\lambda, \mu) = L^\text{res}(\lambda, \mu) \otimes_C \mathbb{C}.$$

This is a highest weight $\mathcal{D}_\xi(g)$-module with highest weight $(\lambda, \mu)$, but it is not always a simple module. As specialization does not change the weight spaces, it is clear that the character of $W_\xi(\lambda, \mu)$ is still given by the Weyl character formula given in section 2.2. The Weyl module is a quotient of the Verma module and it has simple head $L_\xi(\lambda, \mu)$.

Similarly to the case of $q$ generic, we braid the category of representations as in section 2.3.

3.4. Tilting modules. — As for $\mathcal{U}_\xi(g)$, we consider the tilting modules, which have been studied for quantum groups at roots of unity by Andersen in [And92].

Definition 3.5. — A $\mathcal{D}_\xi(g)$-module $M$ is tilting if both $M$ and $M^*$ have a filtration with successive quotients being Weyl modules.

We refer to [Saw06] for more details in the case of $\mathcal{U}_\xi(g)$. We remark that weights $(\lambda, \mu)$ of Weyl modules always satisfy $\lambda + \mu \in 2P$; hence only these weights can appear in a tilting module.

Proposition 3.6. — For any $(\lambda, \mu) \in 2P$, there exists an indecomposable tilting module $T(\lambda, \mu)$ such that $T(\lambda, \mu)_{\lambda, \mu} = 0$ unless $(\lambda', \mu') \leq (\lambda, \mu)$ and $T(\lambda, \mu)_{\lambda, \mu}$ is of dimension one.

Moreover, any indecomposable tilting module is isomorphic to some $T(\lambda, \mu)$.

Proof. — The existence of such tilting modules follows easily from the existence for $\mathcal{U}_\xi(g)$. Indeed, there exists a tilting module for $\mathcal{U}_\xi(g)$ with a maximal vector of weight $\frac{\lambda + \mu}{2}$. Tensoring it with $L_\xi(\frac{\lambda - \mu}{2}, \frac{-\lambda - \mu}{2})$ gives us an indecomposable tilting module with a vector of highest weight $(\lambda, \mu)$.
Let $T$ be an indecomposable tilting module. Using the action of the central elements $z_i\left[ z_i^0, l_i' \right]$ for $1 \leq i \leq n$, one can show that $\lambda - \mu$ does not depend on the weight $(\lambda, \mu)$ of $T$. Therefore, tensoring by \( L_\xi \left( \frac{\mu - \lambda}{2} - \frac{\mu - \lambda}{2} \right) \) gives an indecomposable tilting module for \( \mathcal{U}_\xi(g) \), which is isomorphic to \( T(\kappa, \kappa) \) for some $\kappa \in P^+$.

As a direct summand of a tilting module is again a tilting module, every tilting module is a direct sum of indecomposable tilting modules. Using the fact that the tensor product of two tilting modules for \( \mathcal{U}_\xi(g) \) is again a tilting module, we easily show that the tensor product of two tilting modules for \( \mathcal{G}_\xi(g) \) is again a tilting module.

The full subcategory of \( \mathcal{C}_\xi \) with objects the tilting modules is far from being a fusion category: it is not abelian, nor semisimple. We want to semisimplify this category; hence we must understand which indecomposable tilting modules are of non-zero quantum dimension. As any indecomposable tilting is isomorphic to some \( T(\lambda, \mu) \approx T \left( \frac{\lambda + \mu}{2}, \frac{\lambda + \mu}{2} \right) \otimes L_\xi \left( \frac{\lambda - \mu}{2}, -\frac{\lambda - \mu}{2} \right) \), we can use the results for \( \mathcal{U}_\xi(g) \). The next theorem follows immediately from [Saw06, Theorem 2]. Recall that $D = \max_{\alpha, \beta \in \Phi} \langle \alpha, \beta \rangle$. Let $\theta_0$ be the highest root of $\Phi$ if $D \mid l'$ and be the highest short root of $\Phi$ otherwise. Let $C$ be the following set of dominant weights

\[ C = \{ \lambda \in P^+ \mid \langle \lambda + \rho, \theta_0 \rangle < l' \}. \]

**Theorem 3.7.** — We suppose that \( l' \geq Dh' \) if \( D \mid l' \) and \( l' > h \) otherwise. Then \( T(\lambda, \mu) \) is of non-zero positive and negative quantum dimension if and only if \( \frac{\lambda + \mu}{2} \in C \). Moreover, \( T(\lambda, \mu) \simeq W_\xi(\lambda, \mu) \approx L_\xi(\lambda, \mu) \).

### 3.5. The semisimple category of non-negligible tilting modules —

From now on, we keep the assumption on $l$ of Theorem 3.7. We construct a fusion category using a semisimplification of pivotal categories. As the category of tilting modules is neither abelian, nor spherical, we use the version of semisimplification of pivotal Karoubian categories as in [EO18, 2.3]. The hypothesis of [EO18, Theorem 2.6] are satisfied since

1. the category of tilting modules is a subcategory of an abelian category,
2. up to an invertible element, the positive and negative quantum dimensions of an indecomposable tilting module are equal.

We then denote by \( \mathcal{F}_\xi \) the semisimplification of the category of tilting \( \mathcal{G}_\xi(g) \)-modules. This is a semisimple braided pivotal tensor category and the simple objects are the indecomposable tilting modules $T(\lambda, \mu)$ such that $\frac{\lambda + \mu}{2} \in C$. This category admits a faithful $P$-grading

\[ \mathcal{F}_\xi = \bigoplus_{\nu \in P} \mathcal{F}_{\xi, \nu} \]

where $\mathcal{F}_{\xi, \nu}$ is additively generated by simple objects $L_\xi(\lambda, \mu)$ with $\lambda + \mu = 2\nu$. As in the case of $q$ generic, each component $\mathcal{F}_{\xi, \nu}$ is equivalent to the category of tilting modules for $\mathcal{U}_\xi(g)$.

We now compute explicitly the $S$-matrix and the twist for $\mathcal{F}_\xi$. The $S$-matrix is the matrix indexed by $\text{Irr}(\mathcal{F}_\xi)$ given by

\[ S_{(\lambda, \mu), (\lambda', \mu')} = T_{L_\xi(\lambda, \mu) \otimes L_\xi(\lambda', \mu')}^{-1} \left( C_{L_\xi(\lambda', \mu'), L_\xi(\lambda, \mu)} \circ C_{L_\xi(\lambda, \mu), L_\xi(\lambda', \mu')} \right). \]
The twist $\theta$ and the pivotal structure $a$ are related using the Drinfeld morphism $u$ (see [EGNO15, 8.35]): $a = u \theta$. The latter is given by the composition

$$X \xrightarrow{id_X \otimes \text{coev}_X} X \otimes X^* \xrightarrow{\text{ev}_X \otimes id_{X^*}} X^* \otimes X^*.$$

We recall the expression of the quasi-$R$-matrix $\Theta$ of $\mathcal{D}_\xi(g)$

$$\Theta = \prod_{\alpha \in \Phi^+} \left( \sum_{n=0}^{\infty} \frac{[n]_q}{q_a^n} \left( q_a - q_a^{-1} \right)^n F^{(n)}_a \otimes F^{(n)}_a \right).$$

Recall also that we have chosen the pivotal structure given by the element $L_{2p}$ so that positive and negative quantum traces of any linear map $f : M \rightarrow M$ are given by

$$\text{Tr}_M^+(f) = \text{Tr}(L_{2p} f \mid M) \quad \text{and} \quad \text{Tr}_M^-(f) = \text{Tr}(L_{-2p} f \mid M).$$

**Proposition 3.8.** — Let $(\lambda, \mu)$ and $(\lambda', \mu')$ in $\mathcal{P}^+$. Then the $S$-matrix is given by

$$S_{\lambda,\mu}(\lambda',\mu') = \sum_{w \in W} (-1)^{(1)(w)} \xi(2\rho + \lambda, w \cdot (\lambda', \mu')_2) \xi(\mu, w \cdot (\lambda', \mu'))_1 + 2\rho,$$

and the twist is

$$\theta_{L_{\xi}(\lambda, \mu)} = \xi^{(\lambda + 2\rho, \mu)} \mathbf{id}_{L_{\xi}(\lambda, \mu)}.$$

**Proof.** — Let $L_{\xi}(\lambda, \mu)$ be a simple object in $\mathcal{D}_\xi$. For any other simple object $M$ in $\mathcal{D}_\xi$ the map

$$(\mathbf{id}_{L_{\xi}(\lambda, \mu)} \otimes \text{Tr}_M^+) \circ c_{M, L_{\xi}(\lambda, \mu)} \circ c_{L_{\xi}(\lambda, \mu), M}$$

is an endomorphism of the simple object $L_{\xi}(\lambda, \mu)$ hence is a scalar. We compute it on the highest weight vector $v_{\lambda, \mu}$ of $L_{\xi}(\lambda, \mu)$. Let $m \in M$ be a vector of weight $(\lambda', \mu')$. We have

$$c_{M, L_{\xi}(\lambda, \mu)} \circ c_{L_{\xi}(\lambda, \mu), M}(v_{\lambda, \mu} \otimes m) = \xi^{(\lambda, \mu')} c_{M, L_{\xi}(\lambda, \mu)}(m \otimes v_{\lambda, \mu})$$

as $v_{\lambda, \mu}$ is a vector of highest weight. Now, we take the partial trace of this expression and are interested only in the component on $v_{\lambda, \mu}$. As $F^{(n)}_a v_{\lambda, \mu}$ is not of weight $(\lambda, \mu)$, this shows that only the term $1 \otimes 1$ in $\Theta$ contributes to this component. Therefore

$$(\mathbf{id}_{L_{\xi}(\lambda, \mu)} \otimes \text{Tr}_M^+) \circ c_{M, L_{\xi}(\lambda, \mu)} \circ c_{L_{\xi}(\lambda, \mu), M} = \text{Tr}_M^+ \left( \varphi_M^M \mathbf{id}_{L_{\xi}(\lambda, \mu)} \right)$$

where $\varphi_M^M(m) = \xi^{(\lambda, \mu')} + (\lambda, \mu') m$ for $m$ a vector of weight $(\lambda', \mu')$.

Finally, the $S$-matrix is given by

$$S_{\lambda,\mu}(\lambda',\mu') = \dim^+(L_{\xi}(\lambda, \mu)) \text{Tr}_M^+ \left( \varphi_{\lambda, \mu}^{(\lambda', \mu')} \right).$$

Using the Weyl character formula, we have

$$S_{\lambda,\mu}(\lambda',\mu') = \sum_{w \in W} (-1)^{(1)(w)} \xi(2\rho + \lambda, w \cdot (\lambda', \mu')_2) \xi(\mu, w \cdot (\lambda', \mu'))_1 + 2\rho \sum_{w \in W} (-1)^{(1)(w)} \xi(2\rho + \lambda + \mu, w \cdot 0) \sum_{w \in W} (-1)^{(1)(w)} \xi(2\rho + \lambda, w \cdot 0).$$

Note that the assumption on $l$ ensures that the denominators are non-zero. As we have $(2\rho + \lambda + \mu, w \cdot 0) = (2\rho, (w^{-1} \cdot (\lambda, \mu))_2) - (\mu, 2\rho)$ the formula for the $S$-matrix becomes

$$S_{\lambda,\mu}(\lambda',\mu') = \sum_{w \in W} (-1)^{(1)(w)} \xi(2\rho + \lambda, w \cdot (\lambda', \mu')_2) \xi(\mu, w \cdot (\lambda', \mu'))_1 + 2\rho \sum_{w \in W} (-1)^{(1)(w)} \xi(2\rho, w \cdot 0).$$

We now turn to the twist. Unrolling the definition of the Drinfeld morphism, one can show that for $v_{\lambda, \mu}$ the highest weight vector of $L_{\xi}(\lambda, \mu)$

$$u_{L_{\xi}(\lambda, \mu)}(v_{\lambda, \mu}) = \varphi \mapsto \xi^{-(\lambda, \mu)} \varphi(v_{\lambda, \mu}),$$
whereas
\[ a_{L_{\xi}(\lambda, \mu)}(v_{\lambda, \mu}) = \varphi \mapsto \xi^{(2\rho, \mu)} \varphi(v_{\lambda, \mu}). \]
Therefore we have \( \theta_{L_{\xi}(\lambda, \mu)} = \xi^{(\lambda + 2\rho, \mu)} \text{id}_{L_{\xi}(\lambda, \mu)}. \)

3.6. A partial modularization. — Contrary to the category of tilting modules for \( \mathcal{U}_c(g) \), \( \mathcal{F}_c \) is infinite, since it has an infinite number of non-isomorphic simple objects. Following Müger [Mü00], we first find some objects in the symmetric center of \( \mathcal{F}_c \), and we add isomorphism between these objects and the unit object.

Proposition 3.9. — Let \( \nu \in (l'Q') \cap P \). Then the invertible simple object \( L_{\xi}(\nu, -\nu) \) lies in the symmetric center of \( \mathcal{F}_c \). Its positive and negative quantum dimension is 1 and its twist is 1 or \(-1\).

Proof. — For any simple object \( L_{\xi}(\lambda, \mu) \) in \( \mathcal{F}_c \), we compute \( c_{L_{\xi}(\lambda, \mu), L_{\xi}(\nu, -\nu)} \circ c_{L_{\xi}(\nu, -\nu), L_{\xi}(\lambda, \mu)} \).

As \( L_{\xi}(\nu, -\nu) \otimes L_{\xi}(\lambda, \mu) \) is a simple object, the double braiding is the multiplication by a scalar. By a computation on the highest weight vector, the double braiding is \( \xi^{\langle \nu, \mu - \lambda \rangle} \). But as \( \nu \) is in \( l'Q' \) and \( \mu - \lambda \in 2P \), we have \( (\nu, \mu - \lambda) \in 2l'Z \), so that the double braiding is the identity.

The positive quantum dimension of \( L_{\xi}(\nu, -\nu) \) is given by the action of \( L_{2\rho} \), so is equal to \( \xi^{-\langle 2\rho, \nu \rangle} = 1 \) because \( \rho \in P \).

The twist is given by \( \xi^{\langle \nu, 2\rho, -\nu \rangle} \) which is obviously equal to \( \pm 1 \) since \( \nu \in l'Q' \).}

Let \( \mathcal{S} \) be the tensor subcategory of \( \mathcal{F}_c \) generated by the \( L_{\xi}(\nu, -\nu) \) (which we will denote by \( S(\nu) \)) with \( \nu \in (l'Q') \cap P \) and of twist 1. We recall the construction of the category \( \mathcal{F}_c \times \mathcal{S} \) of [Mü00, Definition 3.12], which is simpler in our case since the objects in \( \mathcal{S} \) are all of dimension 1. We choose for any \( \nu, \nu' \in (l'Q') \cap P \) an isomorphism \( \varphi_{\nu, \nu'} \) in the one dimensional space \( \text{Hom}_{\mathcal{S}}(S(\nu) \otimes S(\nu'), S(\nu + \nu')) \) such that the following commutes
\[
\begin{align*}
S(\nu) \otimes S(\nu') \otimes S(\nu'') &\xrightarrow{\varphi_{\nu, \nu'} \otimes \text{id}} S(\nu + \nu') \otimes S(\nu'') \\
\downarrow\text{id} \otimes \varphi_{\nu, \nu''} &\quad &\downarrow\varphi_{\nu + \nu', \nu''} \\
S(\nu) \otimes S(\nu + \nu') &\xrightarrow{\varphi_{\nu, \nu + \nu''}} S(\nu + \nu' + \nu'')
\end{align*}
\]
To do so, choose in any \( S(\nu) \) a non-zero vector \( v_\nu \). Then \( \varphi_{\nu, \nu'} \) sends \( v_\nu \otimes v_{\nu'} \) to \( v_{\nu + \nu'} \).

We consider the category \( \mathcal{F}_c \times_{\mathcal{S}} \mathcal{S} \) with the same objects as \( \mathcal{F}_c \) and with space of morphisms between two objects \( X \) and \( Y \)
\[ \text{Hom}_{\mathcal{F}_c \times_{\mathcal{S}} \mathcal{S}}(X, Y) = \bigoplus_{\nu \in P \cap l'Q'} \text{Hom}_{\mathcal{F}_c}(X, S(\nu) \otimes Y). \]

The composition of \( f \in \text{Hom}_{\mathcal{F}_c}(X, S(\nu) \otimes Y) \) and of \( g \in \text{Hom}_{\mathcal{S}}(Y, S(\nu') \otimes Z) \) in \( \mathcal{F}_c \times \mathcal{S} \) is given by
\[ X \xrightarrow{f} S(\nu) \otimes Y \xrightarrow{\text{id} \otimes g} S(\nu) \otimes S(\nu') \otimes Z \xrightarrow{\varphi_{\nu, \nu'} \otimes \text{id}} S(\nu + \nu') \otimes Z. \]

Due to the compatibility of the maps \( \varphi \), it is easy to check that this defines an associative composition.

This category has tensor products: on objects the tensor product is the same as the one in \( \mathcal{F}_c \) and if \( f \in \text{Hom}_{\mathcal{F}_c}(X, S(\nu) \otimes Y) \) and \( g \in \text{Hom}_{\mathcal{F}_c}(X', S(\nu') \otimes Y') \), their tensor product is
defined as the composition
\[
X \otimes X' \xrightarrow{f \otimes g} S(v) \otimes S(v') \otimes Y \otimes Y' \xrightarrow{\id \otimes c_{Y,Y'} \otimes \id} S(v) \otimes S(v') \otimes Y \otimes Y'.
\]

Again, the compatibility of \( \varphi \) ensures that this tensor product endows \( \mathcal{T}_\zeta \rtimes_0 \mathcal{F} \) with a structure of a semisimple tensor category, see [Mu00, Section 3.2] for further details.

The duality on \( \mathcal{T}_\zeta \) extends to a duality on \( \mathcal{T}_\zeta \rtimes_0 \mathcal{F} \). One may check that the pivotal structure in \( \mathcal{T}_\zeta \) induces a pivotal structure on \( \mathcal{T}_\zeta \rtimes_0 \mathcal{F} \). It is crucial that the objects in \( \mathcal{F} \) are of twist 1.

Finally, the category \( \mathcal{T}_\zeta \rtimes_0 \mathcal{F} \) is braided because \( \mathcal{F} \) is a subcategory of the symmetric center of \( \mathcal{T}_\zeta \) (see [Mu00, Lemma 3.10]).

Now, in the general case, it can happen that the category constructed above is not idempotent complete. This happens exactly when tensoring by a non-trivial simple object of \( \mathcal{F} \) has a fixed point on the set of simple objects of \( \mathcal{T}_\zeta \). But the object \( S(v) \) is in the component \( \mathcal{T}_\zeta \), of the grading, thus tensoring by this object has no fixed points on the set of simples, provided that \( v \neq 0 \). Therefore the idempotent completion \( \mathcal{T}_\zeta \rtimes_0 \mathcal{F} \) of \( \mathcal{T}_\zeta \rtimes_0 \mathcal{F} \) is \( \mathcal{T}_\zeta \rtimes_0 \mathcal{F} \) itself.

**Proposition 3.10.** — The category \( \mathcal{T}_\zeta \rtimes_0 \mathcal{F} \) is finite.

**Proof.** — Indeed, denoting by \( G \) the quotient of \( P \) by \( \{ v \in (l'Q)^\vee \cap P \mid \theta_S(v) = 1 \} \), \( \mathcal{T}_\zeta \rtimes_0 \mathcal{F} \) is a \( G \)-graded category, with each homogeneous component equivalent to the category of tilting modules for \( \mathcal{H}_\zeta(g) \)

\[
\mathcal{T}_\zeta \rtimes_0 \mathcal{F} = \bigoplus_{v \in G} (\mathcal{T}_\zeta \rtimes_0 \mathcal{F})_v.
\]

Therefore, \( \mathcal{T}_\zeta \rtimes_0 \mathcal{F} \) has \( |C| |G| \) simple objects. Note that \( G \) is indeed finite since \( P / ((IQ)^\vee \cap P) \) surjects on \( G \). □

**3.7. An integral subcategory.** — We consider the full subcategory of \( \mathcal{T}_\zeta \) additively generated by the \( L_\zeta(\lambda, \mu) \) with \( \lambda + \mu \in 2C \) and \( \mu \in Q \). This subcategory is stable by tensor product: we can easily see this at the level of \( \mathcal{H}_\zeta(g) \)-modules. We denote this category by \( \mathcal{Z}(\mathcal{T}_\zeta) \). In the case of the tilting category for \( \mathcal{H}_\zeta(sl_{n+1}) \), Masbaum and Wenzl [MW98] show that an analogue of this subcategory is a modular category provided that \( l \) is even and \( l' \) and \( n + 1 \) are relatively prime.

As for the category \( \mathcal{T}_\zeta \), there are an infinite number of simple objects. But the objects of the form \( S(v) \) with \( v \in (l'Q)^\vee \cap Q \) are in the symmetric center of \( \mathcal{Z}(\mathcal{T}_\zeta) \).

**Lemma 3.11.** — The twist of \( S(v) \) is 1 for any \( v \in (l'Q)^\vee \cap Q \).

**Proof.** — In type \( A \), \( D \) or \( E \) we have \( Q^\vee = Q \) and therefore \( (l'Q)^\vee \cap Q = l'Q \). Hence for \( v = \sum_{i=1}^n \nu_i a_i \), \( \nu_i \in \mathbb{Z} \), we have

\[
\langle v, v \rangle = l^2 \left( \sum_{1 \leq i < j \leq n} 2 \nu_i \nu_j \langle a_i, a_j \rangle + \sum_{i=1}^n \nu_i^2 \langle a_i, a_i \rangle \right) \equiv 0 \mod 2l'
\]

so that all \( S(v) \) with \( v \in (l'Q)^\vee \cap Q \) are of twist 1.

In type \( B \), let \( a_1, \ldots, a_{n-1} \) be the long roots of \( \Delta \) and \( a_n \) the short one. We have \( a_i^\vee = \frac{a_i}{2} \) for \( 1 \leq i \leq n-1 \) and \( a_n^\vee = a_n \). If \( l' \) is odd, then \( (l'Q)^\vee \cap Q = l'Q \) and \( \langle v, v \rangle \equiv 0 \mod 2l' \) as in
the simply laced case. If \( l' \) is even, then \((l'Q^\vee) \cap Q = l'Q^\vee\) and for \( v = \frac{n}{2} \sum_{i=1}^{n-1} v_i \alpha_i + l' v_n \alpha_n, v_i \in \mathbb{Z}, \) we have

\[
(v, v) = \frac{l'^2}{4} \sum_{1 \leq i \leq n-1} v_i v_j (\alpha_i, \alpha_j) + \frac{l'^2}{2} \sum_{i=1}^{n-1} v_i v_n (\alpha_i, \alpha_n) + \frac{l'^2}{2} \sum_{i=1}^{n-1} v_i v_j (\alpha_i, \alpha_j) - v_{n-1} v_n + 2 v_n^2
\]

and since \( \langle a_i, a_j \rangle \) is even for \( 1 \leq i < j \leq n - 1, (v, v) \equiv 0 \mod l'^2. \) As \( l' \) is even, we have \( l = 2l' \) and \( (v, v) \equiv 0 \mod l. \)

In type \( C\), let \( a_1, \ldots, a_{n-1} \) be the short simple roots and \( a_n \) be the long simple root. We have \( a_i^\vee = a_i \) for \( 1 \leq i \leq n-1 \) and \( a_n^\vee = \frac{\alpha_n}{2}. \) If \( l' \) is odd, then \((l'Q^\vee) \cap Q = l'Q^\vee\) and \((v, v) \equiv 0 \mod 2l' \) as in the simply laced case. If \( l' \) is even, \((l'Q^\vee) \cap Q = l'Q^\vee\) and for \( v = \frac{n}{2} \sum_{i=1}^{n-1} v_i \alpha_i + l' v_n \alpha_n, v_i \in \mathbb{Z}, \) we have

\[
(v, v) = \frac{l'^2}{4} \sum_{1 \leq i \leq n-1} v_i v_j (\alpha_i, \alpha_j) + \frac{n}{2} \sum_{i=1}^{n-1} v_i v_n (\alpha_i, \alpha_n) + \frac{v_n^2}{4} (\alpha_n, \alpha_n)
\]

and as \( \langle a_n, a_n \rangle = 4, \) we have \( (v, v) \equiv 0 \mod l'^2. \) As \( l' \) is even, we have \( l = 2l' \) and \( (v, v) \equiv 0 \mod l. \)

In type \( F_4, \) let \( a_1 \) and \( a_2 \) the long simple roots and \( a_3 \) and \( a_4 \) the short simple roots. We have \( a_1^\vee = a_2, a_2^\vee = a_1, a_3^\vee = a_3 \) and \( a_4^\vee = a_4. \) If \( l' \) is odd, then \((l'Q^\vee) \cap Q = l'Q^\vee\) and \((v, v) \equiv 0 \mod 2l' \) as in the simply laced case. If \( l' \) is even, \((l'Q^\vee) \cap Q = l'Q^\vee\) and for \( v = l' \left( \frac{n}{2} \alpha_1 + \frac{\alpha_2}{2} + \varphi_3 \right) + v_n \alpha_4, v_i \in \mathbb{Z}, \) we have

\[
(v, v) = l'^2 (v_1^2 - 2 v_1 v_2 + \frac{2}{3} v_2^2) = 2 l'^2 (3 v_1^2 - 3 v_1 v_2 + v_2^2)
\]

and therefore \( (v, v) \equiv 0 \mod 2l'. \)

Hence, we have shown that for any \( v \in (l'Q^\vee) \cap Q, S(v) \) is of quantum dimension 1 and of twist 1. We again construct the category \( \mathbb{Z}(\mathcal{F}_\zeta) \times \mathcal{O} \) and we obtain a \( P/((l'Q^\vee) \cap Q) \)-graded category

\[
\mathbb{Z}(\mathcal{F}_\zeta) \times \mathcal{O} = \bigoplus_{v \in P/((l'Q^\vee) \cap Q)} \mathbb{Z}(\mathcal{F}_\zeta)_v.
\]

Note that we do not have an equivalence of category between \( \mathbb{Z}(\mathcal{F}_\zeta)_v \) and \( \mathbb{Z}(\mathcal{F}_\zeta)_0 \) if \( v \notin Q. \) But we have an equivalence between \( \mathbb{Z}(\mathcal{F}_\zeta)_v \) and \( \mathbb{Z}(\mathcal{F}_\zeta)_v \) if \( v = v' \in P/Q. \)

**Proposition 3.12.** — The category \( \mathbb{Z}(\mathcal{F}_\zeta) \times \mathcal{O} \) is finite and has \( |C||Q|/(l'Q^\vee) \cap Q || \) simple objects.

**Proof.** — If we choose some representatives \( v_1, \ldots, v_k \) of \( P/Q \) in \( P/((l'Q^\vee) \cap Q), \) we have \( |C| \) simple objects in \( \bigoplus_{i=1}^k \mathbb{Z}(\mathcal{F}_\zeta)_{v_i}. \) Therefore \( \mathbb{Z}(\mathcal{F}_\zeta) \times \mathcal{O} \) has \( |C||Q|/(l'Q^\vee) \cap Q || \) simple objects.

\( \square \)
We end this part with some notation. Denote by $\tilde{C}$ the following set of weights

$$\tilde{C} = \{ (\lambda, \mu) \in P \times Q \mid \lambda + \mu \in 2C \}.$$ 

This set parametrizes the simple objects of $\mathbb{Z}(\mathcal{F})_I$ and the group $I'Q^\vee \cap Q$ acts on it by

$$v \cdot (\lambda, \nu) = (\lambda + v, \mu - v)$$

for $(\lambda, \mu) \in \tilde{C}$ and $v \in (I'Q^\vee) \cap Q$. The set $C = \tilde{C}/((I'Q^\vee) \cap Q)$ parametrizes the simple objects of $\mathbb{Z}(\mathcal{F})_I \times \mathcal{F}$.

### 3.8. Non-degeneracy of $\mathcal{F}_I \times \mathcal{F}$ and degeneracy of $\mathbb{Z}(\mathcal{F})_I \times \mathcal{F}$

In this subsection, we suppose that $l = 2D_d$ for $d \geq h^\vee$. Then $I' = D_d$ and $DdQ^\vee \subseteq Q$ and by Lemma [3.11] for any $v \in DdQ^\vee$, we have $\theta_{s(v)} = 1$.

**Proposition 3.13.** The category $\mathcal{F}_I \times \mathcal{F}$ is non-degenerate.

**Proof.** Using the proof of [BK01 Theorem 3.3.20], we show that the square of the $S$-matrix of $\mathcal{F}_I \times \mathcal{F}$ is invertible. As for any $w \in W$ and $(\lambda, \mu) \in P$ we have

$$w \cdot (\lambda, \mu) = \left( w \cdot \frac{\lambda + \mu}{2}, w \cdot \frac{\lambda + \mu}{2} - \frac{\lambda - \mu}{2} \right),$$

we can rewrite the S-matrix of $\mathcal{F}_I \times \mathcal{F}$ as

$$S_{\lambda, \mu}(\lambda', \mu') = \xi^{(2p, \mu + \eta - \mu', \eta)} \sum_{\eta' \in C} \xi_{\eta, \eta'}^{(\rho + \eta, 2\rho + \eta - \eta')} \tilde{S}_{\eta, \eta'}$$

where $\lambda + \mu = 2\eta$, $\lambda' + \mu' = 2\eta'$ and $\tilde{s}$ is the S-matrix of the modular category of tilting modules for $\mathcal{U}_q(g)$ (see proof of [BK01 Theorem 3.3.20]). The simple objects of $\mathcal{F}_I \times \mathcal{F}$ are indexed by $\{ (\lambda, \mu) \in P \times P \mid \lambda + \mu \in 2C \}/DdQ^\vee$ which is in bijection with $C \times P / DdQ^\vee$ sending $(\lambda, \mu)$ to $(\eta, \mu)$. Therefore

$$(S^2)_{(\lambda, \mu), (\lambda', \mu')} = \xi^{(2p, \mu - \eta + \mu' - \eta')} \sum_{\eta' \in C} \xi_{\eta, \eta'}^{(\rho + \eta, 2\rho + \eta - \eta')} \tilde{S}_{\eta, \eta'}$$

where $\kappa$ is a non-zero constant. As $\mu \in P / DdQ^\vee$, the matrix $S^2$ is, up to a non-zero constant, the invertible permutation matrix $(\delta(\lambda', \mu'), (\lambda, \mu) / \delta(\lambda', \mu')$).

The square of the S-matrix is not given by the duality: this is due to the fact that $\mathcal{F}_I \times \mathcal{F}$ is not spherical, but only pivotal.

Now we turn to the category $\mathbb{Z}(\mathcal{F})_I \times \mathcal{F}$ which is degenerate in general.

**Theorem 3.14.** The symmetric center of $\mathbb{Z}(\mathcal{F})_I \times \mathcal{F}$ contains $\left| P/Q \right|$ simple objects. Therefore, the category $\mathbb{Z}(\mathcal{F})_I \times \mathcal{F}$ is non-degenerate if and only if $g$ is of type $F_4$, $G_2$ or $E_6$.

**Proof.** Using [EGNO03 Lemma 8.20.9], the simple object $L_\xi(\lambda, \mu)$ is in the symmetric center of $\mathbb{Z}(\mathcal{F})_I \times \mathcal{F}$ if and only if

$$(h_{(\lambda, \mu), (0, 0)})_{\mathbb{Z}(\mathcal{F})_I \times \mathcal{F}} = \sum_{(\lambda', \mu') \in C} \frac{\dim L_\xi(\lambda', \mu')}\dim L_\xi(\lambda, \mu) \cdot S_{\lambda, \mu}(\lambda', \mu') S_{\lambda, \mu}(\lambda', \mu') = 0.$$
As in the proof of Proposition 3.13 we let $2\eta = \lambda + \mu$ and $2\eta' = \lambda + \mu'$, which are elements in $C$. We then have

$$
(h_{\lambda, \mu}, h_{0,0})_{Z(\mathcal{F})} = \sum_{\eta \in C} \sum_{\mu' \in Q/DQ^\vee} \xi(2\rho, \eta'-\mu') \xi(2\rho, \eta-\mu'-\eta') \xi(2\mu-\eta, \eta'-\eta') \xi(2\eta, \eta'-\eta') \xi(2\rho, \eta'-\mu') \xi_{\eta', 0} = \xi(2\rho, \eta-\mu) \xi_{\eta, 0} = |Q/DQ^\vee| |\eta|_{\eta'} \xi(2\rho, \eta'-\mu') \xi_{\eta', 0} \xi_{\eta, 0}.
$$

Lemma 3.15. — Let $\gamma \in DdP^\vee$. For any $w \in W$, we have $\gamma - w(\gamma) \in DdQ^\vee$.

**Proof.** — We proceed by induction on the length of $w \in W$. If $l(w) = 0$, the result is trivial. If $l(w) = 1$, we have $w = s_\alpha$ for some $\alpha \in I$. Then we have

$$
\gamma - s_\alpha(\gamma) = \langle \gamma, \alpha \rangle \alpha^\vee,
$$

and since $\gamma \in DdQ^\vee$, the scalar product $\langle \gamma, \alpha \rangle$ is in $DdZ$. Now suppose $l(w) > 1$ and write $w = s_\alpha w'$ for some $w' \in W$, $\alpha \in I$ such that $l(w') = l(w) - 1$. We have

$$
\gamma - w(\gamma) = \gamma - w'(\gamma) + w'(\gamma) - s_\alpha(w'(\gamma))
$$

which is the sum of two elements in $DdQ^\vee$. \(\square\)

Now, fix $\gamma \in DdP^\vee$. Following [BK01] Section 3.3, we have an action of the affine Weyl group $W^a = W \ltimes DdQ^\vee$ on $P$ such that $C$ contains exactly one element for every orbit with trivial stabilizer for the dot action (note that in [BK01] Section 3.3, the translation subgroup of $W^a$ is generated by $dQ^\vee$, but $Q^\vee$ is embedded in $P$ using $D^{-1} \langle \cdot, \cdot \rangle$, so that it coincides with our notations). Using the fact that $s_{\eta, \eta'} = (-1)^{|\eta|} s_{\eta', \eta}$ and Lemma 3.15 we see that $\tilde{s}_{\eta, \eta'} = 0$ is invariant by the action of $W^a$. We therefore can replace the summation on $C$ by a summation on $P/DdQ^\vee$ and we obtain, using the formula of $\tilde{s}$ in the proof of [BK01] Theorem 3.3.20:

$$
\sum_{\eta \in C} \hat{s}_{\eta, \eta'} \hat{s}_{\eta', \eta} \xi(2\rho, \eta'-\mu') \xi_{\eta', 0} = \frac{1}{|W|_{\kappa}} \sum_{w, w' \in W} (-1)^{l(w)+l(w')} \sum_{\eta \in P/DdQ^\vee} \xi(2\rho, \eta, w(\gamma) + w(\rho) + \gamma)
$$

$$
= \frac{|P/DdQ^\vee|}{|W|_{\kappa}} \sum_{w, w' \in W} (-1)^{l(w)+l(w')} \hat{s}_{w(\eta)+\rho, w'(\rho)+\gamma} \xi_{\eta, w_0(\tilde{\gamma}+\rho)}
$$

where $\kappa$ is a non-zero constant.

As $\gamma \in DdP^\vee$ the stabilizer of $\tilde{\gamma}$ for the dot action is trivial, and there exist a unique $\tilde{\gamma} \in C$ and $\tilde{w} \in W$ such that $\gamma + \rho = \tilde{w}(\tilde{\gamma} + \rho) + DdQ^\vee$. Now $w(\eta + \rho) + w'(\rho) + \gamma$ and $\eta + \rho \in C$ if and only if $w(\eta + \rho) \in \gamma - w(\gamma) + DdQ^\vee$. But $w'(\rho) \in \gamma - w'(\gamma) + w'(\tilde{\gamma} + \rho) + DdQ^\vee$ and therefore, using Lemma 3.15, $w(\eta + \rho) + w'(\rho) + \gamma \in DdQ^\vee$ if and only if $\eta + \rho \in w^{-1} w(\tilde{\gamma})$ and $\eta + \rho = w(\tilde{\gamma})$ and $w = w'(\tilde{\gamma})$ and therefore

$$
\sum_{\eta \in C} \hat{s}_{\eta, \eta'} \hat{s}_{\eta', 0} \xi(2\rho, \eta'-\mu') \xi_{\eta, w_0(\tilde{\gamma})} = \kappa (-1)^{l(\tilde{\gamma})+l(w_0(\tilde{\gamma}))} \hat{s}_{\eta, w_0(\tilde{\gamma})}
$$

Therefore, the simple objects in the symmetric center of $Z(\mathcal{F})_{\tilde{\gamma}}$ are indexed by $(\lambda, \mu) \in \tilde{C}$ where $w_{\lambda, \mu} = \gamma \in DdP^\vee / DdQ^\vee$ and $w_{\lambda, \mu} = \gamma \in DdP^\vee / DdQ^\vee$, where $\tilde{\gamma}$ is the only element in $C$ in the orbit of $\gamma$ under the dot action of $W^a$. \(\square\)
4. The type $A$

In this section, we investigate in details the category $\mathbb{Z}(\mathcal{F}_z) \rtimes \mathcal{S}$ for $\mathfrak{sl}_n$ at an even root of unity.

**Notations.** In this section $g = \mathfrak{sl}_{n+1}$ and $\xi$ is a primitive $2d$-th root of unity, where $d \geq n + 1$. To be consistent with the notation of Section 3, we set $l = 2d$ and $l' = d$. We use the conventions of [Bou68, Planche I] for the labelling of roots.

4.1. The category $\mathbb{Z}(\mathcal{F}_z) \rtimes \mathcal{S}$. — In type $A$, we have $\mathcal{S} = Q$ therefore this category has $|C| \mathcal{Q} = d^n |C|$ simple objects. From the description of $C$ given in Section 3.4, we have

$$C = \left\{ \sum_{i=1}^{n} \eta_i \sigma_i \in \mathcal{P} \left| \sum_{i=1}^{n} \eta_i \leq d - (n + 1) \right. \right\}$$

so that $|C| = (d - 1)/n$. Recall the notations $\tilde{C}$ and $\overline{C}$ at the end of Section 3.7.

The category $\mathbb{Z}(\mathcal{F}_z) \rtimes \mathcal{S}$ is not modular by Theorem 3.14. To compute the $n + 1$ simple objects in the symmetric center of $\mathbb{Z}(\mathcal{F}_z) \rtimes \mathcal{S}$, we follow the proof of Theorem 3.14 for every $\gamma \in d \mathcal{P} / d \mathcal{Q}$, we find a representative $\tilde{\gamma} \in C$ of $\gamma$ for the dot action of the affine Weyl group $\mathcal{W}^{n}$. The group $d \mathcal{P} / d \mathcal{Q}$ is generated by the image of $d \sigma_n$ and we have

$$s_n s_{n-1} \cdots s_1 (d \sigma_n + \rho) - \rho \equiv d \sigma_n - \sum_{i=1}^{n} s_n s_{n-1} \cdots s_{n+2-i} (\alpha_{n+1-i}) \mod d \mathcal{Q}.$$

But $s_n s_{n-1} \cdots s_{n+2-i} (\alpha_{n+1-i}) = \sum_{j=n+1-i}^{n} \alpha_j$ and therefore

$$s_n s_{n-1} \cdots s_1 (d \sigma_n) \equiv d \sigma_n - (n + 1) \sigma_n \mod d \mathcal{Q},$$

which is indeed an element of $C$. Therefore the element

$$I = L_{\tilde{\gamma}}((d - (n + 1)) \sigma_1 - d \sigma_n, d - (n + 1)) \sigma_1 + d \sigma_n$$

is in the symmetric center of $\mathbb{Z}(\mathcal{F}_z) \rtimes \mathcal{S}$. As $\sigma_1 + \sigma_n \in \mathcal{Q}$, we have an isomorphism $I \cong L_{\tilde{\gamma}}((2d - (n + 1)) \sigma_1, -(n + 1) \sigma_1)$ in $\mathbb{Z}(\mathcal{F}_z) \rtimes \mathcal{S}$.

**Proposition 4.1.** — The symmetric center of $\mathbb{Z}(\mathcal{F}_z) \rtimes \mathcal{S}$ is generated by $I$ as a tensor category. The object $I$ is of positive and negative quantum dimension $(-1)^n$ and of twist $1$. Moreover, tensorisation by $I$ has no fixed points on the set of simple objects of $\mathbb{Z}(\mathcal{F}_z) \rtimes \mathcal{S}$.

**Proof.** — First, the object $I$ is invertible because the object $L_{\tilde{\gamma}}((d - (n + 1)) \sigma_1, (d - (n + 1)) \sigma_1)$ in $\mathcal{F}_z$ is invertible and the tensor product $L_{\tilde{\gamma}}((d - (n + 1)) \sigma_1, (d - (n + 1)) \sigma_1) \otimes L_{\tilde{\gamma}}(\eta, \eta)$, $\eta = \sum_{i=1}^{n} \eta_i \sigma_i \in C$, is given by

$$L_{\tilde{\gamma}}((d - (n + 1)) \sigma_1, (d - (n + 1)) \sigma_1) \otimes L_{\tilde{\gamma}}(\eta, \eta) \cong L_{\tilde{\gamma}}\left( \sum_{i=1}^{n} \eta_{i-1} \sigma_i, \sum_{i=1}^{n} \eta_{i-1} \sigma_i \right),$$

where we set $\eta_0 = d - (n + 1) - \sum_{i=1}^{n} \eta_i \geq 0$ (see the proof of [Bru00, Lemme 5.1]). Let $(\lambda, \mu) \in \tilde{C}$. Write this weight as

$$\mu = \sum_{i=1}^{n} \mu_i \alpha_i \quad \text{and} \quad \lambda = -\mu + 2 \sum_{i=1}^{n} \eta_i \sigma_i.$$
with \(\mu_i \in \mathbb{Z}, \eta_i \in \mathbb{N}\) and \(\sum_{i=1}^{n} \eta_i \leq d - (n + 1)\). Therefore, using the braiding, we have

\[
I \otimes L_{\xi}(\lambda, \mu) \cong L_{\xi}\left(\lambda + \sum_{i=1}^{n} (\eta_{i-1} - \eta_i)\sigma_i + d\sigma_1, \mu + \sum_{i=1}^{n} (\eta_{i-1} - \eta_i)\sigma_i - d\sigma_1\right).
\]

From this, we see that the objects \(I^{\otimes k}\) for \(0 \leq k \leq n\) are non-isomorphic. Since \(I\) is in the symmetric center of \(\mathbb{Z}(\mathcal{F}_\xi) \rtimes \mathcal{F}\), which contains \(|P/Q| = n + 1\) simple objects, all the simple objects in this symmetric center are given by the powers of \(I\).

We can compute the quantum dimension directly in \(\mathcal{C}_\xi\). As a \(\mathcal{U}_\xi(\mathfrak{sl}_{n+1})\)-module, the quantum dimension of \(L_{\xi}(d-(n+1))\sigma_1, (d-(n+1))\sigma_1\) is 1: this object is invertible and its quantum dimension is positive [BK01, Theorem 3.3.9]. Therefore, the positive quantum dimension of \(I\) is the one of \(L_{\xi}(d\sigma_1, -d\sigma_1)\) which is \(\xi^{-d(2\rho, \sigma_1)} = (-1)^n\).

The twist is given by \(\xi^{[(2d-(n+1))\sigma_1 + 2\rho, -(n+1)\sigma_1]} = \xi^{-2dn} = 1\). The last assertion is easy, since the grading of \(I\) is \(d\sigma_1 \notin d\mathcal{Q}\).

4.2. Dimension of \(\mathbb{Z}(\mathcal{F}_\xi) \rtimes \mathcal{F}\) and renormalization. — Thanks to the decomposition \(L_{\xi}(\lambda, \mu) \cong L_{\xi}\left(\frac{\lambda + \mu}{2}, \frac{\lambda + \mu}{2}\right) \otimes L_{\xi}\left(\frac{\lambda - \mu}{2}, -\frac{\lambda - \mu}{2}\right)\) the squared norm of \(L_{\xi}(\lambda, \mu)\) is the same as the one of \(L_{\xi}\left(\frac{\lambda + \mu}{2}, \frac{\lambda + \mu}{2}\right)\). Therefore

\[
\dim(\mathbb{Z}(\mathcal{F}_\xi) \rtimes \mathcal{F}) = d^n N,
\]

where \(N\) is the dimension of the fusion category of tilting modules for \(\mathcal{U}_\xi(\mathfrak{sl}_{n+1})\), which is well known (see [BK01, Theorem 3.3.20], except our \(N\) is their \(D^2\))

\[
N = (n + 1)d^n (-1)^{|\Phi^+|} \prod_{\alpha \in \Phi^+} \frac{1}{(\xi^{(a, \rho)} - \xi^{- (a, \rho)})^2}.
\]

The Weyl character formula gives

\[
\prod_{\alpha \in \Phi^+} \xi^{(a, \rho)} - \xi^{- (a, \rho)} = \xi^{-2(\rho, \rho)} \sum_{\mathcal{C}_{n+1}} (-1)^{l(w)} \xi^{(2\rho, w[0])}.
\]

Now, as the category \(\mathbb{Z}(\mathcal{F}_\xi) \rtimes \mathcal{F}\) is degenerate, we construct a non-degenerate category from it. If \(n\) is even, all elements in the symmetric center are of quantum dimension 1 and of twist 1: adding an isomorphism between \(I\) and \(1\) as in Sections 3.6 and 3.7 yields a non-degenerate category of dimension

\[
\frac{\dim(\mathbb{Z}(\mathcal{F}_\xi) \rtimes \mathcal{F})}{n + 1} = d^{2n} (-1)^{|\Phi^+|} \xi^{-(2\rho, 2\rho)} \left(\sum_{w \in \mathcal{C}_{n+1}} (-1)^{l(w)} \xi^{(2\rho, w[0])}\right)^{-2}.
\]

If \(n\) is odd, one half of the objects of the symmetric center are of quantum dimension 1 and of twist 1 and the other half is of quantum dimension −1 and of twist 1. We first add an isomorphism between \(I \otimes I\) and \(1\) and we obtain a slightly degenerate category of superdimension

\[
\frac{\dim(\mathbb{Z}(\mathcal{F}_\xi) \rtimes \mathcal{F})}{n + 1} = d^{2n} (-1)^{|\Phi^+|} \xi^{-(2\rho, 2\rho)} \left(\sum_{w \in \mathcal{C}_{n+1}} (-1)^{l(w)} \xi^{(2\rho, w[0])}\right)^{-2},
\]

see [Lac18] for more details. By adding an isomorphism of odd degree between \(I\) and \(1\), we obtain a braided pivotal superfusion category, as in [Lac18, Section 3].

In both cases, the category obtained is not spherical and we renormalize the \(S\)-matrix by a factor involving the dimension on a certain object \(1\) introduced in [Lac18]: it is an
object $X$ such that the character induced by $X$ on $\text{Gr}(\mathcal{Z}(\mathcal{F}_\xi) \times \mathcal{F})$ is the negative quantum dimension. If such an object exists, it is not unique as tensorization by the symmetric center leaves invariant the character induced at the level of the Grothendieck group. Therefore, if $n$ is even, $\mathbf{1}$ is well defined in the modularization of $\mathcal{Z}(\mathcal{F}_\xi) \times \mathcal{F}$, and if $n$ is odd, it is well defined in the super category associated to $\mathcal{Z}(\mathcal{F}_\xi) \times \mathcal{F}$.

**Proposition 4.2.** — The object $\mathbf{1}$ belongs to the orbit of $L_\xi(-2\rho, 2\rho)$ under tensorisation by the symmetric center.

**Proof.** — We show that the character of $\text{Gr}(\mathcal{Z}(\mathcal{F}_\xi) \times \mathcal{F})$ induced by $L_\xi(-2\rho, 2\rho)$ is the negative quantum dimension. Denote by $\chi$ the character of $\text{Gr}(\mathcal{Z}(\mathcal{F}_\xi) \times \mathcal{F})$ defined by

$$\chi(X) = \frac{S_{L_\xi(-2\rho, 2\rho), X}}{\dim^+(L_\xi(-2\rho, 2\rho))}.$$  

The formula for the $S$-matrix, together with $\dim^+(L_\xi(-2\rho, 2\rho)) = \xi^{(2\rho, 2\rho)}$ gives

$$\chi(L_\xi(\lambda, \mu)) = \sum_{w \in \mathcal{S}_{n+1}} (-1)^{(w)\lambda} \xi^{(2\rho, 2\rho)} \sum_{w \in \mathcal{S}_{n+1}} (-1)^{(w)\lambda} \xi^{(2\rho, w^* \mu)}.$$  

It is easy to check that $w \cdot (-2\rho, 2\rho) = w \cdot (0, 0) + (-2\rho, 2\rho)$ and therefore

$$\langle \lambda + 2\rho, (w \cdot (-2\rho, 2\rho))_2 \rangle + \langle (w \cdot (-2\rho, 2\rho))_1 + 2\rho, \mu \rangle - (2\rho, 2\rho)$$

$$= \langle \lambda + \mu + 2\rho, w(\rho) \rangle + \left( \frac{\lambda - \mu}{2}, 2\rho \right)$$

$$= \left( w^{-1} \cdot \frac{\lambda + \mu}{2}, 2\rho \right) + \left( \frac{\lambda - \mu}{2}, 2\rho \right).$$

Then, the value of $\chi$ at $L_\xi(\lambda, \mu)$ is given by

$$\chi(L_\xi(\lambda, \mu)) = \xi^{(\frac{\lambda - \mu}{2})} \sum_{w \in \mathcal{S}_{n+1}} (-1)^{(w)\lambda} \xi^{(\frac{\lambda + \mu}{2}, 2\rho)}$$

$$= \dim^+(L_\xi(\frac{\lambda - \mu}{2}, 2\rho)) \dim^+(L_\xi(\frac{\lambda + \mu}{2}, 2\rho))$$

as stated. $\square$

Finally, we renormalize $S$ with a square root of

$$\frac{\dim(\mathcal{Z}(\mathcal{F}_\xi) \times \mathcal{F})}{n + 1} \dim^+(\mathcal{I}) = d^{2n} (-1)^{\Phi^1 + n} \left( \sum_{w \in \mathcal{S}_{n+1}} (-1)^{(w)\lambda} \xi^{(2\rho, w^* \mu)} \right)^{-2},$$

which is

$$d^{n \Phi^1 + n} \left( \sum_{w \in \mathcal{S}_{n+1}} (-1)^{(w)\lambda} \xi^{(2\rho, w^* \mu)} \right)^{-1}$$

up to a sign.

We choose for each orbit of simple objects of $\mathcal{Z}(\mathcal{F}_\xi) \times \mathcal{F}$ a representative of the orbit under tensorisation by the symmetric center, such that $\mathbf{1}$ is the representative of the orbit of $\mathbf{1}$ and $1 \otimes L_\xi(-2\rho, 2\rho)$ is the representative of the orbit of $L_\xi(-2\rho, 2\rho)$. This choice will be explained in Section 5.4.
Theorem 4.3. — If $n$ is even, the category $\mathcal{Z}(\mathcal{C}) \rtimes \mathcal{C}$ gives rise to a non-degenerate braided pivotal fusion category. If $n$ is odd, the category $\mathcal{Z}(\mathcal{C}) \rtimes \mathcal{C}$ gives rise to a non-degenerate braided pivotal superfusion category. In both cases the renormalized $S$-matrix is given by

$$\tilde{S}_{\lambda,\mu}(\lambda',\mu') = i^{-n-\phi} \sum_{w \in W} (-1)^{l(w)} \xi(2p + \lambda(\lambda',\mu')) + (\mu(\lambda',\mu')) + 2p$$

and the twist by

$$\theta_{\lambda,\mu} = \xi^{(\lambda+2p,\mu)}.$$

5. Malle $\mathbb{Z}$-modular datum

We refer to [Mal95] and [Cun07] for most of the materials of this section. Let $\zeta$ be a primitive $d$-th root of unity.

5.1. Set up. — Let $Y = \{1, 2, \ldots, nd + 1\}$ of cardinal $nd + 1$ and $\pi : Y \to \mathbb{N}$ be the map defined by

$$\pi(k) = \begin{cases} n & \text{if } 1 \leq k \leq n+1, \\ \frac{k-n-2}{d} & \text{if } n+2 \leq k \leq nd+1. \end{cases}$$

Let $\Psi(Y, \pi)$ be the set of maps $f : Y \to \{0, 1, \ldots, d-1\}$ such that $f$ is strictly increasing on each $\pi^{-1}(i)$, $0 \leq i \leq n$. Since for $0 \leq i \leq n-1$ the set $\pi^{-1}(i)$ is of cardinal $d-1$, there exists a unique element $k_i(f) \in \{0, \ldots, d-1\}$ such that $\{0, \ldots, d-1\} = f(\pi^{-1}(i)) \cup \{k_i(f)\}$. Note that $f$ is then determined by the values of $f(1) < \cdots < f(n+1)$ and of $k_0(f), \ldots, k_{n-1}(f)$. For $f \in \Psi(Y, \pi)$, we set
g(f) = (-1)^{\sum_{(y, y') \in Y \times Y} y < y' \text{ and } f(y) < f(y')}.

Let $V$ be a $\mathbb{C}$-vector space of dimension $d$ with basis $(v_i)_{0 \leq i \leq d-1}$. We denote by $\mathcal{C}$ the square matrix $(\zeta^{i_j})_{0 \leq i, j \leq d-1}$ and we will view it as an endomorphism of $V$. We set $\tau(d) = (-1)^{d(d-1)/2} \det(\mathcal{C}) = \prod_{0 \leq i < j \leq d-1}(\zeta^{i} - \zeta^{j})$. We consider the automorphism of the vector space $\left(\wedge^{n+1} V \otimes \wedge^{d-1} V\right)^{\otimes n}$ given by $\left(\wedge^{n+1} \mathcal{C} \otimes \wedge^{d-1} \mathcal{C}\right)^{\otimes n}$. This space has a basis given by

$$V_f = (v_{f(1)} \wedge \cdots \wedge v_{f(n+1)}) \otimes (v_{f(n+2)} \wedge \cdots \wedge v_{f(n+d)}) \otimes \cdots \otimes (v_{f(n+2+(n-1)(d-1))} \wedge \cdots \wedge v_{f(n+d-1)})$$

for $f \in \Psi(Y, \pi)$. Denote by $S$ the matrix of $\left(\wedge^{n+1} \mathcal{C} \otimes \wedge^{d-1} \mathcal{C}\right)^{\otimes n}$ in the basis $(V_f)_{f \in \Psi(Y, \pi)}$

$$(\left(\wedge^{n+1} \mathcal{C} \otimes \wedge^{d-1} \mathcal{C}\right)^{\otimes n}(V_f) = \sum_{g \in \Psi(Y, \pi)} S_{f,g} V_g.$$

The following lemma follows immediately from [BR17] Lemma 6.2.

Lemma 5.1. — Let $f, g \in \Psi(Y, \pi)$. Then we have

$$S_{f,g} = (-1)^{\sum_{i=0}^{n-1}(k_i(f)+k_i(g))} \frac{(-1)^{nd(d-1)/2} \tau(d)}{d^n} \prod_{i=0}^{n-1} \zeta^{-k_i(f)k_i(g)} \sum_{\sigma \in S_{n+1}} (-1)^{l(\sigma)} \prod_{i=1}^{n+1} \zeta^{-f(i)g(\sigma(i))}.$$
5.2. Malle $\mathbb{Z}$-modular datum. — Following [Mal95], we consider the family $\mathcal{F}$ of unipotent characters of $G\left(d, 1, \frac{n(n+1)}{2}\right)$ parametrized by reduced $d$-symbols with values in the multiset
\[\{0^{d-1}, 1^{d-1}, \ldots, (n-1)^{d-1}, n^{n+1}\}.
\]
These $d$-symbols are in bijection with the set
\[\Psi^d(Y, \pi) = \left\{ f \in \Psi(Y, \pi) \left| \sum_{y \in Y} f(y) \equiv n \left(\frac{d}{2}\right) \pmod{d} \right. \right\}.
\]
Indeed to $f \in \Psi^d(Y, \pi)$ we associate the reduced $d$-symbol $S = (S_0, \ldots, S_{d-1})$ with entries $i \in S_j$ for all $j \in f(\pi^{-1}(i))$. We define for $f \in \Psi^d(Y, \pi)$
\[\text{Fr}(f) = \tau_n^{d(1-d^2)} \prod_{y \in Y} \tau_n^{-6f(y)^2 + df(y)},
\]
where $\zeta$ is a primitive $12d$-th root of unity such that $\zeta^12 = \zeta$. Denote by $\mathbb{T}$ the diagonal matrix with entries $(\text{Fr}(f))_{f \in \Psi^d(Y, \pi)}$.

Following [Cun07] Section 5], we denote by $S = (S_{f.g})_{f,g \in \Psi^d(Y, \pi)}$ the square matrix defined by
\[S_{f,g} = \frac{(-1)^{n(d-1)}}{\tau(d)^n} S_{f,g}.
\]

Define $f_0 \in \Psi^d(Y, \pi)$ by $f(i) = i - 1$ for $1 \leq i \leq n + 1$ and $k_j(f) = j + 1$ for $0 \leq j \leq n - 1$. Note that $S_{f_0,g} \neq 0$ for all $g \in \Psi^d(Y, \pi)$ as it is, up to a non-zero constant, the value of a Vandermonde determinant. The following is due to Malle [Mal95 4.15].

**Proposition 5.2.** — We have
1. $\mathcal{S}^d = (\mathcal{S}T)^3 = [\mathcal{S}^2, \mathcal{T}] = 1$.
2. $S$ is symmetric and unitary.
3. For all $f, g, h \in \Psi^d(Y, \pi)$ the numbers
\[N^h_{f,g} = \sum_{k \in \Psi^d(Y, \pi)} \frac{S_{f,k}S_{g,k}S_{h,k}}{S_{f_0,k}}
\]
belong to $\mathbb{Z}$.

The special symbol also parametrizes a complex representation of $G\left(d, 1, \frac{n(n+1)}{2}\right)$ and the complex conjugate of this representation is parametrized by the cospecial symbol, see [Mal95 2.A, 2.D] for more details. Explicitely, the cospecial symbol $f_\infty$ is given by
\[f(i) = \begin{cases} 0 & \text{if } i = 1 \\ d - n + i - 2 & \text{otherwise} \end{cases} \quad \text{and} \quad k_i(f) = d - i - 1.
\]

We will compare this modular datum to the one constructed in Theorem 4.3. For this, we rewrite the expressions of $S$ and $\mathbb{T}$. First, note that $f \in \Psi(Y, \pi)$ is in $\Psi^d(Y, \pi)$ if and only if
\[\sum_{i=1}^{n+1} f(i) \equiv \sum_{i=0}^{n-1} k_i(f) \pmod{d}.
\]
Therefore, we get rid of $f(n+1)$ in the expressions of $S$ and $\mathbb{T}$.
Proposition 5.3. — For \( f, g \in \Psi(Y, \pi) \) we have
\[
\text{Fr}(f) = \zeta \sum_{n} (k_{n-1}(f) - f(i)) \left( \sum_{j=1}^{n} f(j) - \sum_{j=1}^{n-1} k_{j-1}(f) \right)
\]
and
\[
S_{f,g} = \frac{1}{d^n} \varepsilon(f)\varepsilon(g)(-1)^{\sum_{j=1}^{n} (k_{j-1}(f) + k_{j-1}(g))} \sum_{\sigma \in \mathcal{S}_{n+1}} (-1)^{\lvert \sigma \rvert} \sum_{i=1}^{n} \left( (k_{i-1}(f) - f(i)) \left( \sum_{j=1}^{n} (\sigma \cdot g)(j) - \sum_{j=1}^{n-1} (\sigma \cdot g)(j) \right) \right)
\]

Proof. — Let us begin by the value of \( \text{Fr}(f) \). By definition, \( \text{Fr}(f) = \xi_a \) where
\[
a = nd(1-d^2) - 6 \sum_{y \in Y} (f(y)^2 + df(y)).
\]
which we consider \( a \) as an element of \( \mathbb{Z}/12d\mathbb{Z} \). First, as \( \{0, \ldots, d-1\} = f(\pi^{-1}(i)) \cup \{k_i(f)\} \) for \( 0 \leq i \leq n-1 \), we have
\[
\sum_{y \in Y} (f(y)^2 + df(y)) = \sum_{i=1}^{n+1} (f(i)^2 + df(i)) + n \sum_{i=0}^{d-1} (i^2 + di) - \sum_{i=1}^{n} (k_{i-1}(f)^2 + dk_{i-1}(f)).
\]
But
\[
6 \sum_{i=0}^{d-1} (i^2 + di) = (d-1)d(2d-1) + 3d^2(d-1) = d(d-1)(5d-1)
\]
and therefore
\[
d(1-d^2) - 6 \sum_{i=0}^{d-1} (i^2 + di) = 6d^2(1-d) \equiv 0 \mod 12d,
\]
so that
\[
a = -6 \left( \sum_{i=1}^{n+1} (f(i)^2 + df(i)) - \sum_{i=1}^{n} (k_{i-1}(f)^2 + dk_{i-1}(f)) \right).
\]

Fix \( \eta \in \mathbb{Z} \) such that \( f(n+1) = \sum_{i=0}^{n} (k_{i-1}(f) - f(i)) + \eta d \), so that we have
\[
f(n+1)^2 + df(n+1) = \left( \sum_{i=1}^{n} (k_{i-1}(f) - f(i)) \right)^2 + 2d \eta \sum_{i=1}^{n} (k_{i-1}(f) - f(i)) + d^2 \eta (1 + \eta) \equiv 0 \mod 2d,
\]

Finally
\[
a = -6 \left( \sum_{i=1}^{n} (k_{i-1}(f) - f(i)) \right)^2 + \sum_{i=1}^{n} (k_{i-1}(f)^2 - f(i)^2)
\]
\[
= 12 \left( \sum_{i=1}^{n} f(i)(k_{i-1}(f) - f(i)) - \sum_{1 \leq j < i < n} (k_{i-1}(f) - f(i))(k_{j-1}(f) - f(j)) \right)
\]
\[
= 12 \sum_{i=1}^{n} (k_{i-1}(f) - f(i)) \left( \sum_{j=1}^{i} f(j) - \sum_{j=1}^{i-1} k_{j-1}(f) \right)
\]
which gives the expected formula for \( \text{Fr}(f) \).
We now turn to the formula for $S$. Since $\frac{\gamma(d)}{d^n} = (-1)^{[d-1]/2} \frac{\gamma(d)}{d}$ we have

$$S_{f,g} = \frac{(-1)^{\sum_{i=0}^{n-1}(k_i(f)+k_i(g))}}{d^n} \prod_{i=0}^{n-1} \xi^{k_i(f)k_i(g)} \sum_{\sigma \in S_{n+1}} \epsilon(\sigma) \prod_{i=1}^{n+1} \xi^{\sigma(i)(\sigma_i)(i)}.$$  

Fix $\sigma \in S_{n+1}$ and let $h = \sigma \cdot g$. Then

$$\sum_{i=1}^{n} k_{i-1}(f)k_{i-1}(h) - \sum_{i=1}^{n+1} f(i)h(i) = \sum_{i=1}^{n} (k_{i-1}(f)k_{i-1}(h) - f(i)h(i)) - \sum_{1 \leq i, j \leq n} (k_{i-1}(f) - f(i))(k_{i-1}(h) - h(i))$$

$$= \sum_{i=1}^{n} (k_{i-1}(f) - f(i))h(i) + \sum_{i=1}^{n} (k_{i-1}(h) - h(i))f(i) - \sum_{1 \leq i \neq j \leq n} (k_{i-1}(f) - f(i))(k_{i-1}(h) - h(i))$$

$$= \sum_{i=1}^{n} \left[ (k_{i-1}(f) - f(i)) \left( \sum_{j=1}^{i} h(j) - \sum_{j=1}^{i-1} k_{j-1}(h) \right) + (k_{i-1}(h) - h(i)) \left( \sum_{j=1}^{i} f(j) - \sum_{j=1}^{i-1} k_{j-1}(f) \right) \right].$$

Hence, taking the sum on $\sigma \in S_{n+1}$, we obtain the second formula. \hfill \qed

5.3. Ennola duality. — For each $d$-symbol $S$ in the family $\mathcal{F}$, Malle defined a polynomial $\gamma_S(q)$, which have similar properties to the degree of a unipotent character for a finite group of Lie type. These polynomials satisfy the Ennola property: there exists a bijection $\mathcal{E} : \mathcal{F} \rightarrow \mathcal{F}$ such that for every symbol $S$ in the family $\mathcal{F}$, $\gamma_S(\zeta q) = \pm \gamma_{\mathcal{E}(S)}$. The symbol $\mathcal{E}(S)$ is explicitly given in the proof of [Ma95, Folgerung 3.11]. We describe it at the level of functions in $\Psi^\#(Y, \pi)$. Let $f \in \Psi^\#(Y, \pi)$, its Ennola dual $\mathcal{E}(f)$ is given by the unique function $g$ such that

$$k_i(g) = \left( k_i(f) + i - \frac{n(n+3)}{2} \right)^{\text{res}}$$

and

$$\{ g(i) \mid 1 \leq i \leq n+1 \} = \left\{ \left( f(i) - \frac{n(n+1)}{2} \right)^{\text{res}} \mid 1 \leq i \leq n+1 \right\},$$

$(k)^{\text{res}}$ being the remainder in the Euclidean division of $k$ by $d$.

5.4. Comparison with the modular datum of the category $\mathbb{Z}(\mathcal{F}_\zeta) \rtimes \mathcal{F}$. — We now compare the modular datum of Malle with the modular datum of Theorem 4.3 from which we use the notation. To each function $f \in \Psi^\#(Y, \pi)$ we associate $\mu = \sum_{i=1}^{n} \mu_i \sigma_i \in Q$ and $\lambda = -\mu + 2 \sum_{i=1}^{n} \eta_i \sigma_i \in P$ with

$$\mu_i = \sum_{j=1}^{i-1} k_{j-1}(f) - \sum_{j=1}^{i} f(j) \quad \text{and} \quad \eta_i = f(i+1) - f(i) - 1.$$  

As $f$ takes its values in $[0, \ldots, d-1]$ and is strictly increasing on $\{1, \ldots, n+1\}$ we have $\sum_{i=1}^{n} \eta_i \leq d - 1 - n$ and therefore $\lambda + \mu \in 2C$. We then obtain a map

$$\iota : \left\{ \begin{array}{ccc} \Psi^\#(Y, \pi) & \longrightarrow & \overline{C} \\ f & \longrightarrow & (\lambda_f, \mu_f) \end{array} \right..$$
Note that the special symbol $f_0$ is sent to $(0,0)$ and the cospecial symbol is sent to $(-2\rho + (2d-(n+1))\sigma_1, 2\rho -(n+1)\sigma_1)$. We define a left inverse to $\iota$ as follows. Let $(\lambda, \mu) \in \mathbb{C}$ and define $f_{\lambda, \mu}$ as the unique function $f \in \Psi(Y, \pi)$ such that

$$[f(1), \ldots, f(n+1)] = \left[ -\langle \mu, \sigma_1 \rangle + \sum_{j=1}^{i-1} \left( \frac{\lambda + \mu}{2} + \rho, a_j \right) \right]_{1 \leq i \leq n+1}$$

and

$$k_{i-1}(f) = \left( \sum_{j=1}^{i-1} \left( \frac{\lambda - \mu}{2} + \rho, a_j \right) \right)_{\text{res}}.$$ 

An easy computation shows that $f_{\lambda, \mu}$ belongs to $\Psi^\lambda(Y, \pi)$ and that $f_{\iota(f)} = f$ for any $f \in \Psi^\lambda(Y, \pi)$. A straightforward computation shows the following lemma.

**Lemma 5.4.** — Let $f, g \in \Psi^\lambda(Y, \pi)$. With the previous notation we have

$$\langle \lambda_f + 2\rho, \mu_g \rangle + \langle \lambda_g + 2\rho, \mu_f \rangle = -\sum_{i=1}^{n} (k_{i-1}(f) - f(i)) \left( \sum_{j=1}^{i} g(j) - \sum_{j=1}^{i-1} k_{j-1}(g) \right)$$

$$-\sum_{i=1}^{n} (k_{i-1}(g) - g(i)) \left( \sum_{j=1}^{i} f(j) - \sum_{j=1}^{i-1} k_{j-1}(f) \right)$$

Now, let $\zeta = \xi^{-2}$. It follows immediately that

$$T_f = \theta_{L\zeta(\lambda_f, \mu_f)}$$

and noticing that $\iota(\sigma \cdot f) = s \bullet \iota(f)$ (where we extend $\iota$ to all functions $f : Y \to \{0, \ldots, d-1\}$ such that $f$ is injective on each $\pi^{-1}(i)$, the action of $\mathfrak{S}_{n+1}$ being induced by the action on the $\{1, \ldots, n+1\} \subset Y$) we have

$$S_{f,g} = \sum_{w \in \mathfrak{S}_{n+1}} (-1)^{|w|} \zeta^{(2\rho, w*0)} \epsilon(f) \epsilon(g)(-1)^{\sum_{i=1}^{n} k_{i-1}(f) + k_{i-1}(g)} \epsilon(\lambda_f, \mu_f)(\lambda_g, \mu_g).$$

Let $P$ be the diagonal matrix with diagonal entries $(\epsilon(f)(-1)^{\sum_{i=1}^{n} k_{i-1}(f)})_{f \in \Psi^\lambda(Y, \pi)}$. We can now state the main theorem of this paper.

**Theorem 5.5.** — If $n$ is even (resp. odd) the braided pivotal fusion category (resp. braided pivotal superfusion category) of $\mathfrak{L}_\zeta$ is a categorification of the Malle $\mathbb{Z}$-modular datum:

$$S_{f,g} = i^{-|\Phi| - n} PS_{(f), (g)} P^{-1} \quad \text{and} \quad T_f = \theta_{L\zeta(\iota(f))}.$$

**Remark.** — The image of $\iota$ contains exactly one representative of each orbit of simple objects of $\mathbb{Z}(\mathfrak{T}_\zeta) \rtimes \mathcal{F}$ under tensorisation by the symmetric center. As $I \otimes L\zeta(-2\rho, 2\rho)$ is in the image of $\iota$, this justifies our choice of $I$ made in Section 4.1.

### 5.5. Categorification of the Ennola property.

The Ennola duality gives a bijection $\mathcal{E}$ on $\Psi^\lambda(Y, \pi)$ and satisfies $\mathcal{E}^d = \text{id}$. Consider $(-\gamma, \gamma)$ in $\mathbb{C}$ given by $\gamma = \frac{(n+1)(n+2)}{2} \sigma_1 - \rho$.

**Proposition 5.6.** — Tensoring by $L\zeta(-\gamma, \gamma)$ is a categorification the Ennola duality. For any $f \in \Psi^\lambda(Y, \pi)$ we have

$$L\zeta(\iota(f)) \otimes L\zeta(-\gamma, \gamma) \simeq L\zeta(\iota(\mathcal{E}(f))),$$

the isomorphism being understood in the non-degenerate (super)fusion category associated to $\mathbb{Z}(\mathfrak{T}_\zeta) \rtimes \mathcal{F}$.
As γ belongs to $Q^\vee$, it is clear that $L_\xi(-\gamma,\gamma)^{ad} \cong 1$.

**Proof.** — We write γ on the basis of simple roots

$$\gamma = \frac{1}{2} \sum_{i=1}^{n} (n-i+1)(n-i+2)\alpha_i.$$  

Let $f \in \Psi^b(Y, \pi)$ and let $(\lambda, \mu) = \pi(f) + (-\gamma, \gamma)$. Writing as usual $\mu = \sum_{i=1}^{n} \mu_i \alpha_i$ and $\lambda = -\mu + 2 \sum_{i=1}^{n} \eta_i \sigma_i$ we have

$$\mu_i = \sum_{j=1}^{i-1} k_{j-1}(f) - \sum_{j=1}^{i} f(j) + \frac{(n-i+1)(n-i+2)}{2} \quad \text{and} \quad \eta_i = f(i+1) - f(i)-1.$$  

By definition, $f_{\lambda,\mu}$ is the unique function $g \in \Psi^b(Y, \pi)$ such that

$$\{g(1), \ldots, g(n+1)\} = \left\{ \left( (-\mu, \sigma_1) + \sum_{j=1}^{i-1} \left( \frac{\lambda+\mu}{2} + \rho, \alpha_j \right) \right)^{\text{res}} \right\} \quad \text{for } 1 \leq i \leq n+1$$

and

$$k_{i-1}(g) = \left( \sum_{j=1}^{i} \left( \frac{\lambda-\mu}{2} + \rho, \alpha_j \right) \right)^{\text{res}}.$$  

But as

$$-\langle \mu, \sigma_1 \rangle + \sum_{j=1}^{i-1} \left( \frac{\lambda+\mu}{2} + \rho, \alpha_j \right) = f(i) - \frac{n(n+1)}{2}$$

and

$$\sum_{j=1}^{i} \left( \frac{\lambda-\mu}{2} + \rho, \alpha_j \right) = f(i+1) - \frac{n(n+1)}{2} + \mu_{i+1} - \mu_i = k_{i-1}(f) - \frac{n(n+1)}{2} + \frac{(n-i)(n-i+1)}{2} - \frac{(n-i+1)(n-i+2)}{2} = k_{i-1}(f) + i - 1 - \frac{n(n+3)}{2},$$

we have $f_{\lambda,\mu} = f_{i}^{(\sigma(f))}$. As the fibres of the map $(\lambda, \mu) \mapsto f_{\lambda,\mu}$ are exactly the orbits under tensorisation by the symmetric center on the set of simple objects of $Z(\mathcal{F}) \times \mathcal{X}$, there exists $k \in \mathbb{Z}$ such that $L_\xi(i(f)) \otimes L_\xi(-\gamma, \gamma) \cong L_\xi(i(\sigma(f))) \otimes I^{\otimes k}$.

---

### 6. Z-modular data associated to exceptional complex reflection groups

The notion of “unipotent characters” has been defined for some exceptional complex reflection group by Broué, Malle and Michel [BMM99, BMM14], which are called spetsial. The notion of families of such characters, as well as of Fourier transform and eigenvalues of the Frobenius exists, and are available in the package CHEVIE of GAP [GHL96, Mic15]. In this section, we categorify some of these Z-modular data using subcategories of $Z(\mathcal{F}) \times \mathcal{X}$, for a well suited simple complex Lie algebra g and $\xi$ a well chosen root of unity. The unipotent characters of a complex reflection group $G$ are obtained in CHEVIE and displayed with the following command (we do the example of $G_4$):
Unipotent characters for $G_4$

| Name | Degree | FakeDegree | Eigenvalue | Label |
|------|--------|------------|------------|-------|
| *phi(1,0) | 1 | 1 | 1 |
| *phi(2,1) | $(3-\text{ER}(-3))/6qP'3P4P''6$ | qP4 | 1 | $1.\text{E}3$ |
| #phi(2,3) | $(3+\text{ER}(-3))/6qP''3P4P''6$ | $q^3P4$ | 1 | $1.\text{E}3^2$ |
| Z3:2 | -ER(-3)/3qP1P2P4 | 0 | E3$^2$ | E3.$\text{E}3^2$ |
| *phi(3,2) | $q^2P3P6$ | $q^2P3P6$ | 1 |
| *phi(4,1) | -ER(-3)/6qP''3P4P''6 | $q^4$ | 1 | $-1.\text{E}3^2$ |
| phi(2,5) | $1/2q^4P^2P6$ | $q^5P4$ | 1 | $1.\text{E}3^2$ |
| G4 | $-1/2q^4P^1P^2P3$ | 0 | -1 | $-1.\text{E}3^2.-1$ |
| Z3:11 | -ER(-3)/3qP1P2P4 | 0 | E3$^2$ | E3.-E3 |
| #phi(1,8) | $\text{ER}(-3)/6qP'3P4P''6$ | $q^8$ | 1 | $1.\text{E}3^2$ |

One can access to a family, to its Fourier matrix and to the eigenvalues of the Frobenius as follows (continuing the same example):

```gap
gap> f:=U.families[2];
Family("RZ/3^2",[6,5,8])
gap> f.fourierMat;
[ [ -2/3*E(3)-1/3*E(3)^2, -1/3*E(3)-2/3*E(3)^2, -1/3*E(3)+1/3*E(3)^2 ],
  [ -2/3*E(3)-2/3*E(3)^2, -1/3*E(3)-1/3*E(3)^2, 1/3*E(3)-1/3*E(3)^2 ],
  [ -1/3*E(3)+1/3*E(3)^2, 1/3*E(3)-1/3*E(3)^2, 1/3*E(3)-1/3*E(3)^2 ] ]
gap> f.eigenvalues
[ 1, 1, E(3)^2 ]
```

6.1. Two families attached to $G_{27}$. — We consider the complex reflection group denoted by $G_{27}$ in the classification of Shephard-Todd [ST54]. Two families of unipotent characters are of cardinal 18, the second one and the last but one. The Z-modular datum they define are complex conjugate to each other, hence we will only consider the second family of unipotent characters of $G_{27}$. The Z-modular datum is in fact the tensor product of a Z-

6.1.1. The Z-modular datum of cardinal 3. — The Fourier matrix and the eigenvalues of the Frobenius are

$$S = \frac{1}{3} \begin{pmatrix}
1 - \zeta_3 & 1 - \zeta_3^2 & \zeta_3 - \zeta_3^2 \\
1 - \zeta_3^2 & 1 - \zeta_3 & \zeta_3^2 - \zeta_3 \\
\zeta_3 - \zeta_3^2 & \zeta_3^2 - \zeta_3 & \zeta_3^3 - \zeta_3^2
\end{pmatrix} \quad \text{and} \quad T = \begin{pmatrix}
1 & 0 & 0 \\
0 & 1 & 0 \\
0 & 0 & \zeta_3^2
\end{pmatrix}$$

where $\zeta_3$ is a primitive third root of unity. It is easily checked that it coincides with the Z-modular datum associated to the non-trivial family of the cyclic complex reflection group $G(3,1,1)$. By Theorem [5.5], this Z-modular datum is categorifed by the braided pivotal slightly degenerate fusion category $\mathcal{Z}(\mathcal{F}\zeta) \rtimes \mathcal{Y}$ for $g = \text{sl}_2$ and $\zeta$ a sixth root of unity such that $\zeta^2 = \zeta^{-1}$. 

```
6.1.2. The \(N\)-modular datum of cardinal 6. — The Fourier matrix and the eigenvalues of the Frobenius are

\[
S = \frac{1}{10} \begin{pmatrix}
-\zeta_5^4 + \zeta_5^2 + \zeta_5 & -\zeta_5^4 + \zeta_5^2 + \zeta_5 - \zeta_5^{-1} & -\zeta_5^4 + \zeta_5^2 + \zeta_5 - \zeta_5^{-1} & -\zeta_5^4 + \zeta_5^2 + \zeta_5 - \zeta_5^{-1} & -\zeta_5^4 + \zeta_5^2 + \zeta_5 - \zeta_5^{-1} & 2(-\zeta_5^4 + \zeta_5^2 + \zeta_5 - \zeta_5^{-1}) & 2(-\zeta_5^4 + \zeta_5^2 + \zeta_5 - \zeta_5^{-1}) & 2(-\zeta_5^4 + \zeta_5^2 + \zeta_5 - \zeta_5^{-1}) & -5 & -5 \\
-\zeta_5^4 + \zeta_5^2 + \zeta_5 & -\zeta_5^4 + \zeta_5^2 + \zeta_5 - \zeta_5^{-1} & -\zeta_5^4 + \zeta_5^2 + \zeta_5 - \zeta_5^{-1} & -\zeta_5^4 + \zeta_5^2 + \zeta_5 - \zeta_5^{-1} & -\zeta_5^4 + \zeta_5^2 + \zeta_5 - \zeta_5^{-1} & 2(-\zeta_5^4 + \zeta_5^2 + \zeta_5 - \zeta_5^{-1}) & 2(-\zeta_5^4 + \zeta_5^2 + \zeta_5 - \zeta_5^{-1}) & 2(-\zeta_5^4 + \zeta_5^2 + \zeta_5 - \zeta_5^{-1}) & 5 & 5 \\
2(-\zeta_5^4 + \zeta_5^2 + \zeta_5 - \zeta_5^{-1}) & 2(-\zeta_5^4 + \zeta_5^2 + \zeta_5 - \zeta_5^{-1}) & 2(3\zeta_5^4 + 2\zeta_5^2 + 3\zeta_5) & 2(-2\zeta_5^4 + 3\zeta_5^2 + 2\zeta_5) & 0 & 0 \\
2(-\zeta_5^4 + \zeta_5^2 + \zeta_5 - \zeta_5^{-1}) & 2(-\zeta_5^4 + \zeta_5^2 + \zeta_5 - \zeta_5^{-1}) & 2(-2\zeta_5^4 + 3\zeta_5^2 + 2\zeta_5) & 2(3\zeta_5^4 + 2\zeta_5^2 + 3\zeta_5) & 0 & 0 \\
-5 & 5 & 0 & 0 & 0 & 0 & 0 & -5 & 5 & -5 \\
-5 & 5 & 0 & 0 & 0 & 0 & 0 & -5 & 5 & -5
\end{pmatrix}
\]

and

\[
T = \begin{pmatrix}
1 & 0 & 0 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 & 0 & 0 \\
0 & 0 & \zeta_5^3 & 0 & 0 & 0 \\
0 & 0 & 0 & \zeta_5^2 & 0 & 0 \\
0 & 0 & 0 & 0 & -1 & 0 \\
0 & 0 & 0 & 0 & 0 & 1
\end{pmatrix},
\]

where \(\zeta_5\) is a primitive fifth root of unity.

**Notation.** In this section, \(g\) is of type \(B_2\) with Cartan matrix

\[
\begin{pmatrix}
2 & -2 \\
-1 & 2
\end{pmatrix}.
\]

The short simple root is denoted by \(\alpha_1\) and the long simple root is denoted by \(\alpha_2\). The fundamental weights are \(\sigma_1 = \alpha_1 + \frac{1}{2} \alpha_2\) and \(\sigma_2 = \alpha_1 + \alpha_2\).

Let \(\xi\) be a primitive twentieth root of unity such that \(\xi^4 = \zeta_5\) and consider the full subcategory \(\mathcal{C}\) of \(\mathcal{Z}(\mathcal{F}) \times \mathcal{Y}\) for \(g\) of type \(B_2\) generated by the objects of grading 0 and 5\(\sigma_1\). As 10\(\sigma_1\in 10Q^Y \cap Q\), \(\{0,5\sigma_1\}\) is a subgroup of \(P/(10Q^Y \cap Q)\). Hence \(\mathcal{C}\) is stable by tensor product. The fundamental chamber \(C\) is given by

\[
C = \{\lambda_1 \sigma_1 + \lambda_2 \sigma_2 \in P^+ | \lambda_1 + \lambda_2 < 3\} = \{0, \sigma_1, \sigma_2, \sigma_1 + \sigma_2, 2\sigma_1, 2\sigma_2\}.
\]

Therefore, there are 6 simple objects in \(\mathcal{C}\) which are labelled by:

- in degree 0: \((0,0),(\sigma_2, \sigma_2), (2\sigma_1, 2\sigma_1)\) and \((2\sigma_2, 2\sigma_2)\),
- in degree 5\(\sigma_1\): \((6\sigma_1, -4\sigma_2)\) and \((6\sigma_1 + \sigma_2, -4\sigma_1 + \sigma_2)\).

We choose the following set of representatives of the fusion category \(\mathcal{C}\):

\[
\{L_\xi(0,0), L_\xi(2\sigma_2, 2\sigma_2), L_\xi(2\sigma_1, 2\sigma_1), L_\xi(\sigma_2, \sigma_2), L_\xi(6\sigma_1 + \sigma_2, -4\sigma_1 + \sigma_2), L_\xi(6\sigma_1, -4\sigma_2)\}
\]

With this order, the \(S\)-matrix and the \(T\)-matrix of the twist of \(\mathcal{C}\) are

\[
S_\xi = \begin{pmatrix}
1 & 1 & 2 & 2 & \zeta_5^4 - \zeta_5^2 - \zeta_5 + \zeta_5^{-1} & \zeta_5^4 + \zeta_5^2 - \zeta_5 - \zeta_5^{-1} & \zeta_5^4 + \zeta_5^2 - \zeta_5 - \zeta_5^{-1} \\
1 & 1 & 2 & 2 & \zeta_5^4 - \zeta_5^2 - \zeta_5 + \zeta_5^{-1} & \zeta_5^4 + \zeta_5^2 - \zeta_5 - \zeta_5^{-1} & \zeta_5^4 + \zeta_5^2 - \zeta_5 - \zeta_5^{-1} \\
2 & 2 & 2\zeta_5^2 + 2\zeta_5 & 2\zeta_5^2 + 2\zeta_5^2 & 0 & 0 & 0 \\
2 & 2 & 2\zeta_5^2 + 2\zeta_5 & 2\zeta_5^2 + 2\zeta_5 & 0 & 0 & 0 \\
\zeta_5^4 - \zeta_5^2 + \zeta_5 & \zeta_5^4 - \zeta_5^2 + \zeta_5 & 0 & 0 & \zeta_5^4 - \zeta_5^2 - \zeta_5 + \zeta_5^{-1} & \zeta_5^4 + \zeta_5^2 - \zeta_5 - \zeta_5^{-1} & \zeta_5^4 + \zeta_5^2 - \zeta_5 - \zeta_5^{-1} \\
\zeta_5^4 - \zeta_5^2 + \zeta_5 & \zeta_5^4 - \zeta_5^2 + \zeta_5 & 0 & 0 & \zeta_5^4 - \zeta_5^2 - \zeta_5 + \zeta_5^{-1} & \zeta_5^4 + \zeta_5^2 - \zeta_5 - \zeta_5^{-1} & \zeta_5^4 + \zeta_5^2 - \zeta_5 - \zeta_5^{-1}
\end{pmatrix},
\]

and

\[
T_\xi = \begin{pmatrix}
1 & 0 & 0 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 & 0 & 0 \\
0 & 0 & \zeta_5^3 & 0 & 0 & 0 \\
0 & 0 & \zeta_5^2 & 0 & 0 & 0 \\
0 & 0 & 0 & -1 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 1
\end{pmatrix}.
\]
Renormalizing $S_\mathcal{C}$ with the square root of 20, which is the dimension of $\mathcal{C}$, gives us the opposite of the matrix $S$.

**Theorem 6.1.** — The $S$-matrix and the $T$-matrix of the modular category $\mathcal{C}$ satisfy

$$
\frac{S_\mathcal{C}}{\sqrt{20}} = -S \quad T_\mathcal{C} = T.
$$

**Remark.** — The category $\mathcal{C}$ is indeed ribbon since every object is self dual.

### 6.2. Two families attached to $G_{24}$.

We consider the complex reflection group denoted by $G_{24}$ in the classification of Shephard-Todd [ST54]. Two families of unipotent characters are of cardinal 7, the second one and the last but one. The $\mathbb{Z}$-modular datum they define are complex conjugate to each other, hence we will only consider the last but one family of unipotent characters of $G_{24}$.

The Fourier matrix and the eigenvalues of the Frobenius are

$$
S = \frac{1}{14} \begin{pmatrix}
-\sqrt{7} & \sqrt{7} & 7 & 7 & -2\sqrt{7} & -2\sqrt{7} & -2\sqrt{7} \\
\sqrt{7} & -\sqrt{7} & 7 & 7 & 2\sqrt{7} & 2\sqrt{7} & 2\sqrt{7} \\
7 & 7 & -7 & -7 & 0 & 0 & 0 \\
-2\sqrt{7} & 2\sqrt{7} & 0 & 0 & 2\zeta_7^2 + 4\zeta_7^3 + 4\zeta_7^4 - 2\zeta_7^5 & -4\zeta_7^2 + 2\zeta_7^3 + 2\zeta_7^4 - 2\zeta_7^5 + 4\zeta_7^6 & -4\zeta_7^2 - 2\zeta_7^3 + 2\zeta_7^4 - 2\zeta_7^5 + 4\zeta_7^6 \\
-2\sqrt{7} & 2\sqrt{7} & 0 & 0 & -4\zeta_7^2 + 2\zeta_7^3 + 2\zeta_7^4 - 2\zeta_7^5 + 4\zeta_7^6 & -4\zeta_7^2 - 2\zeta_7^3 + 2\zeta_7^4 - 2\zeta_7^5 + 4\zeta_7^6 & 2\zeta_7^2 + 4\zeta_7^3 - 4\zeta_7^4 - 2\zeta_7^5 - 2\zeta_7^6 \\
-2\sqrt{7} & 2\sqrt{7} & 0 & 0 & -4\zeta_7^2 - 2\zeta_7^3 + 2\zeta_7^4 + 4\zeta_7^5 & 2\zeta_7^2 + 4\zeta_7^3 - 4\zeta_7^4 - 2\zeta_7^5 - 2\zeta_7^6 & -4\zeta_7^2 + 2\zeta_7^3 - 2\zeta_7^4 + 4\zeta_7^5 + 4\zeta_7^6
\end{pmatrix}
$$

and

$$
T = \begin{pmatrix}
1 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & -1 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & \zeta_7^3 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & \zeta_7^3 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & \zeta_7^6
\end{pmatrix},
$$

where $\zeta_7$ is a primitive seventh root of unity and $\sqrt{-7} = \zeta_7 + \zeta_7^2 = \zeta_7^3 + \zeta_7^4 - \zeta_7^5 = \zeta_7^6$. In [Cun05], Section 8.2.1 Beispiel 15, Cuntz showed that the fusion algebra associated to this modular datum is related to the Verlinde algebra of type $B_3$ at a twenty-eighth root of unity.

Let $\xi$ be a primitive twenty-eighth root of unity such that $\xi^4 = \zeta_7$ and consider the category $\mathbb{Z}(\mathcal{F}_2) \rtimes \mathcal{C}$ for $\mathcal{C}$ of type $B_3$.

**Notations.** In this section, $\mathcal{C}$ is of type $B_3$ with Cartan matrix

$$
\begin{pmatrix}
2 & -2 & 0 \\
-1 & 2 & -1 \\
0 & -1 & 2
\end{pmatrix}.
$$

The short simple root is denoted by $\alpha_1$ and the two long simple roots are denoted by $\alpha_2$ and $\alpha_3$. The fundamental weights are $\omega_1 = \frac{1}{2} \alpha_1 + \alpha_2 + \frac{1}{2} \alpha_3$, $\omega_2 = 2 \alpha_1 + 2 \alpha_2 + \alpha_3$ and $\omega_3 = \alpha_1 + \alpha_2 + \alpha_3$.

We have $\omega_1 = \frac{3}{2} \alpha_1 + 2 \alpha_2 + \alpha_3$ and therefore the subgroup of $P/(14Q^\vee \cap Q)$ generated by $7\omega_1$ is $\{0, 7\omega_1, 14\omega_1, 21\omega_1\}$. Let $\mathcal{C}$ be the full subcategory of $\mathbb{Z}(\mathcal{F}_2) \rtimes \mathcal{C}$ generated by the
objects of grading in \(\{0, 7\sigma_1, 14\sigma_1, 21\sigma_1\}\). This category is then stable by tensor product. The fundamental chamber \(C\) is

\[
C = \{\lambda_1 \sigma_1 + \lambda_2 \sigma_2 + \lambda_3 \sigma_3 \in P^* | \lambda_1 + 2\lambda_2 + \lambda_3 < 3\} = \{0, \sigma_1, \sigma_2, \sigma_3, 2\sigma_1, 2\sigma_3, \sigma_1 + \sigma_3\}.
\]

Therefore, there are 14 simple objects in \(\mathcal{C}\) which are labelled by:
- in degree 0: \((0,0), (\sigma_2, \sigma_3), (\sigma_3, \sigma_3), (2\sigma_1, 2\sigma_1)\) and \((2\sigma_3, 2\sigma_3)\),
- in degree 7\(\sigma_1\): \((8\sigma_1, -6\sigma_1)\) and \((8\sigma_1 + \sigma_3, -6\sigma_1 + \sigma_3)\),
- in degree 14\(\sigma_1\): \((14\sigma_1, -14\sigma_1), (14\sigma_1 + \sigma_2, -14\sigma_1 + \sigma_2), (14\sigma_1 + \sigma_3, -14\sigma_1 + \sigma_3), (16\sigma_1, -12\sigma_1)\) and \((14\sigma_1 + 2\sigma_3, -14\sigma_1 + 2\sigma_3)\)
- in degree 21\(\sigma_1\): \((22\sigma_1, -20\sigma_1)\) and \((22\sigma_1 + \sigma_3, -20\sigma_1 + \sigma_1)\).

**Proposition 6.2.** — The category \(\mathcal{C}\) is slightly degenerate. The non-unit object of its symmetric center is \(L_\xi(14\sigma_1 + 2\sigma_3, -14\sigma_1 + 2\sigma_3)\) which is of dimension \(-1\) and of twist 1.

We choose the following set of representatives of the superfusion category \(\hat{\mathcal{C}}\):

\[
\{L_\xi(0,0), L_\xi(14\sigma_1, -14\sigma_1), L_\xi(22\sigma_1, -20\sigma_1), L_\xi(22\sigma_1 + \sigma_3, -20\sigma_1 + \sigma_3), L_\xi(\sigma_3, \sigma_3), L_\xi(\sigma_2, \sigma_1), L_\xi(2\sigma_1, 2\sigma_1)\}.
\]

With this order, the \(S\)-matrix and the \(T\)-matrix of the twist of \(\hat{\mathcal{C}}\) are

\[
S_{\hat{\mathcal{C}}} = \begin{pmatrix}
1 & -1 & \sqrt{-7} & \sqrt{-7} & 2 & 2 & 2 \\
-1 & 1 & \sqrt{-7} & \sqrt{-7} & -2 & -2 & -2 \\
\sqrt{-7} & \sqrt{-7} & \sqrt{-7} & -\sqrt{-7} & 0 & 0 & 0 \\
\sqrt{-7} & \sqrt{-7} & -\sqrt{-7} & \sqrt{-7} & 0 & 0 & 0 \\
2 & -2 & 0 & 0 & 2\zeta_7^5 + 2\zeta_7^3 & 2\zeta_7^5 + 2\zeta_7^3 & 2\zeta_7^4 + 2\zeta_7^5 \\
2 & -2 & 0 & 0 & 2\zeta_7^5 + 2\zeta_7^3 & 2\zeta_7^5 + 2\zeta_7^3 & 2\zeta_7^4 + 2\zeta_7^5 \\
2 & -2 & 0 & 0 & 2\zeta_7^5 + 2\zeta_7^3 & 2\zeta_7^5 + 2\zeta_7^3 & 2\zeta_7^4 + 2\zeta_7^5 \\
\end{pmatrix}
\]

and

\[
T_{\hat{\mathcal{C}}} = \begin{pmatrix}
1 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & -1 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & \zeta_7^3 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & \zeta_7^5 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & \zeta_7^6 \\
\end{pmatrix}
\]

This category is not spherical and the object \(I\) is \(L_\xi(14\sigma_1, -14\sigma_1)\), which is of dimension \(-1\). Therefore following \([\text{Lac}18]\) Theorem 2.7, we renormalise \(S_{\hat{\mathcal{C}}} \) with the square root of \(-28\), which is \(\text{sdim}(\mathcal{C}) \dim^+(I)\).

**Theorem 6.3.** — The \(S\)-matrix and the \(T\)-matrix of the superfusion category \(\hat{\mathcal{C}}\) satisfy

\[
\frac{S_{\hat{\mathcal{C}}}}{i\sqrt{28}} = S \quad \text{and} \quad T_{\hat{\mathcal{C}}} = T,
\]

where \(i = \zeta_7^7\).
