SIEGEL MODULAR FORMS OF WEIGHT 13 AND THE LEECH LATTICE

GAËTAN CHENEVIER AND OLIVIER TAÏBI

ABSTRACT. For $g = 8,12,16$ and $24$, there is an alternating $g$-multilinear form on the Leech lattice, unique up to scalar, which is invariant by the orthogonal group of Leech. The harmonic Siegel theta series built from these alternating forms are Siegel modular cuspforms of weight $13$ for $\text{Sp}_{2g}(\mathbb{Z})$. We prove that they are nonzero eigenforms, determine one of their Fourier coefficients, and give informations about their standard $L$-functions. These forms are interesting since, by a recent work of the authors, they are the only nonzero Siegel modular forms of weight $13$ for $\text{Sp}_{2n}(\mathbb{Z})$, for any $n \geq 1$.

INTRODUCTION

Let $L$ be an even unimodular lattice of dimension $24$. We know since Conway and Niemeier that either $L$ has no root, and is isomorphic to the Leech lattice (denoted Leech below), or $L \otimes \mathbb{R}$ is generated by the roots of $L$ [CS99, Chap. 16]. In the latter case, it follows that for any integer $g \geq 1$ there is no nonzero alternating $g$-form on $L$ which is invariant by its orthogonal group $O(L)$ (see §4). On the other hand, $O(\text{Leech})$ is Conway’s group $\text{Co}_0$ and a computation made in [Che], using the character $\chi_{102}$ and the power maps given in the ATLAS [CCN+85], revealed that the average characteristic polynomial of an element of $O(\text{Leech})$ is

$$\frac{1}{|\text{Co}_0|} \sum_{\gamma \in \text{Co}_0} \det(t - \gamma) = t^{24} + t^{16} + t^{12} + t^8 + 1.$$  

(1)

It follows that for $g$ in $\{8,12,16,24\}$, and only for those values of $g \geq 1$, there is a nonzero alternating $g$-multilinear form, unique up to a rational scalar,

$$\omega_g : \text{Leech}^g \to \mathbb{Q}$$

such that $\omega_g(\gamma v_1, \gamma v_2, \ldots, \gamma v_g) = \omega_g(v_1, v_2, \ldots, v_g)$ for all $\gamma \in O(\text{Leech})$ and all $v_1, \ldots, v_g$ in Leech.

A first natural question is to exhibit concretely these $\omega_g$. Of course, we may choose for $\omega_{24}$ the determinant taken in a $\mathbb{Z}$-basis of Leech: it is indeed $O(\text{Leech})$-invariant as we know since Conway [Con69] that any element in $O(\text{Leech})$ has determinant $1$, a non trivial fact. We will explain in §1 a simple and uniform

---

Gaëtan Chenevier and Olivier Taibi are supported by the C.N.R.S. and by the project ANR-14-CE25.
construction of $\omega_8, \omega_{12}$ and $\omega_{16}$. It will appear that it is not an accident that the numbers 0, 8, 12, 16 and 24 are also the possible length of an element in the extended binary Golay code.

A second interesting question is to study the Siegel theta series

$$F_g \overset{\text{def}}{=} \sum_{v \in \text{Leech}^g} \omega_g(v) q^{v \cdot v}.$$  

Here $v \cdot v$ abusively denotes the Gram matrix $(v_i \cdot v_j)_{1 \leq i, j \leq 9}$ with $v = (v_1, \ldots, v_9)$, and $q^n$ abusively denotes the the function $\tau \mapsto e^{2\pi i n \tau}$ for $\tau \in \text{M}_g(\mathbb{C})$ in the Siegel upper-half space. This theta series is a Siegel modular form of weight 13 for the full Siegel modular group $\text{Sp}_{2g}(\mathbb{Z})$, necessarily a cuspidal form, whose Fourier coefficients are in $\mathbb{Q}$. The first paragraph above even shows that this is an eigenform... provided it is nonzero! (see §4).

Among these four forms, only $F_{24}$ seems to have been studied in the past, by Freitag, in the last section of [Fre82]. He observed that $F_{24}$ is indeed a nonzero eigenform. Indeed, if we choose $\omega_{24}$ as above, and if $u \in \text{Leech}^{24}$ is a $\mathbb{Z}$-basis of Leeuch with $\omega_{24}(u) = 1$, there are exactly $|O(\text{Leech})|$ vectors $v \in \text{Leech}^{24}$ with $v \cdot v = u \cdot u$, namely the $\gamma u$ with $\gamma$ in $O(\text{Leech})$. They all satisfy $\omega_{24}(v) = 1$ since any element of $O(\text{Leech})$ has determinant 1. It follows that the Fourier coefficient of $F_{24}$ in $q^{u \cdot u}$ is $|O(\text{Leech})|$, it is thus nonzero.

Nevertheless, the following theorem was recently proved in [CT, Cor. 1 & Prop. 5.12]:

**Theorem 1.** For $g \geq 1$ the space of weight 13 Siegel modular forms for $\text{Sp}_{2g}(\mathbb{Z})$ is 0, or we have $g \in \{8, 12, 16, 24\}$, it has dimension 1, and is generated by $F_g$.

The proof given loc. cit. of the non vanishing of the forms $F_g$ is quite indirect. Using quite sophisticated recent results from the theory of automorphic forms (Arthur's classification [Art13], recent description by Arancibia, Moeglin and Renard of certain local Arthur packets [AMR, MR]) we observed the existence of 4 weight 13 Siegel modular eigenforms for $\text{Sp}_{2g}(\mathbb{Z})$ of respective genus $g = 8, 12, 16$ and 24, and with specific standard $L$-function. The cases $g = 16$ and $g = 24$ are especially delicate, and use recent results of Moeglin and Renard [MR]. Using works of Böcherer [Bö89], we then checked that they must be linear combinations of Siegel theta series construction from alternating $g$-multilinear forms on Niemeier lattices, hence must be equal to $F_g$ by what we explained above. Our aim here is to provide a more direct and elementary proof of the non vanishing of the 3 remaining forms $F_g$, by exhibiting a nonzero Fourier coefficient.

Let $F = \sum_n a_n q^n$ be a Siegel modular form for $\text{Sp}_{2g}(\mathbb{Z})$ of odd weight, and $N$ an even Euclidean lattice of rank $g$. If $v$ and $v'$ in $\tilde{N}^g$ are $\mathbb{Z}$-bases of $N$, with associated Gram matrices $2n$ and $2n'$, we have $a_n = (\det \gamma) a_{n'}$ where $\gamma$ is the unique element of $\text{GL}(N)$ with $\gamma(v) = v'$. In particular, the element $\pm a_n$ (a complex number modulo sign) only depends on the isometry class of $N$, and will
be denoted \( a_N(F) \) and called the \( N \)-th Fourier coefficient of \( F \). For instance, we have \( a_{\text{Leech}}(F_{24}) = \pm |O(\text{Leech})| \). We will say that a lattice \( N \) is orientable if any element of \( O(N) \) has determinant 1; note that we have \( a_N(F) = 0 \) for all non-orientable even lattice \( N \) of rank \( g \).

Four orientable rank \( g \) even lattices \( Q_g \) with \( g \in \{ 8, 12, 16, 24 \} \) will play an important role below. The lattice \( Q_{24} \) is simply Leech. The lattice \( Q_{12} \) is the unique even lattice \( L \) of rank 12 without roots with \( L^2/L \simeq (\mathbb{Z}/3\mathbb{Z})^6 \); it is also known as the Coxeter-Todd lattice [CS99, Ch. 4 \S9]. The lattices \( Q_8 \) and \( Q_{16} \) are the unique even lattices \( L \) without roots, of respective rank 8 and 16, with \( L^2/L \simeq (\mathbb{Z}/5\mathbb{Z})^4 \); the lattice \( Q_8 \) was known to Maass and is sometimes called the icosian lattice [CS99, Ch. 8 \S2]. These properties, and other relevant ones for our purposes, will be reviewed or proved in \$2 \) and \$3. An important one is that there is a unique \( O(\text{Leech}) \)-orbit of sublattices of Leech isometric to \( Q_g \). Our main result is the following.

**Theorem 2.** For each \( g \), the \( Q_g \)-Fourier coefficient of \( F_g \) is nonzero. More precisely, if we normalize \( \omega_g \) as in Definition 1.5, we have

\[
a_{Q_g}(F_g) = \pm n_g e_g,
\]

where \( n_g \) is the number of isometric embeddings \( Q_g \hookrightarrow \text{Leech}, \) and with \( e_8 = e_{16} = 5 \), \( e_{12} = 18 \) and \( e_{24} = 1 \).

As we will see, the quantity \( e_g \) has the following conceptual explanation in terms of the extended binary Golay code \( G \) and its automorphism group \( M_{24} \). Write \( \text{res} \, Q_g \simeq (\mathbb{Z}/p_g\mathbb{Z})^{r_g} \); then \( e_g \) is the number of \( g \)-element subsets of \( G \) containing the fixed point set of a given element of \( M_{24} \) of shape \((1^{24-r_g}) \cdot p_g^{r_g} \) (Lemmas 2.3 & 2.4). We will also prove \( n_g = |O(\text{Leech})|/\kappa_{24-g} \), with \( \kappa_g = 1 \) for \( g \leq 12 \), \( \kappa_{12} = 3 \) and \( \kappa_{16} = 10 \). We would like to stress that our proof of Theorem 2 does not rely on any computer calculation other than the simple summations (1) and (1.1).

Last but not least, we discuss in the last section the standard \( L \)-functions of the eigenforms \( F_g \); see Theorem 4.4. This last part is less elementary than the others, and relies on [Art13, AMR, Tai19] (but not on [MR]).

We end this introduction by discussing prior works on the determination of the spaces \( M_k(\text{Sp}_{2g}(\mathbb{Z})) \) of Siegel modular forms of weight \( k \) for \( \text{Sp}_{2g}(\mathbb{Z}) \), and its subspace \( S_k(\text{Sp}_{2g}(\mathbb{Z})) \) of cuspforms, for \( k < 13 \). For this purpose, the subspace \( \Theta^g_{k} \) of \( M_n(\text{Sp}_{2g}(\mathbb{Z})) \) generated by (classical) Siegel theta series of even unimodular lattices of rank \( 2n \) has drawn much attention, starting with Witt’s famous conjecture \( \dim \Theta^g_{k} = 2 \iff g \geq 4 \), proved by Igusa. The study of \( \Theta^g_{12} \) has a rich history as well. Erokhin proved \( \dim \Theta^g_{12} = 24 \) for \( g \geq 12 \) in [Ero79], and Borcherds-Freitag-Weissauer showed \( \dim \Theta^{12}_{12} = 23 \) in [BFW98]. Nebe and Venkov conjectured in [NV01] that the 11 integers \( \dim \Theta^g_{12} \), for \( g = 0, \ldots, 10 \), are respectively given by

\[
1, 2, 3, 4, 6, 8, 11, 14, 18, 20 \text{ and } 22.
\]
and proved it for $g \neq 7, 8, 9$. Ikeda used his “lifts” [Ike01, Ike06] to determine the standard $L$-functions of 20 of the 24 eigenforms in $\Theta_{12}^g$. The full Nebe-Venkov conjecture was finally proved by Chenevier-Lannes [CL19], as well as the determination of the 4 standard $L$-functions not determined by Ikeda. Moreover, these authors show $\Theta_{12}^g = M_{12}(\text{Sp}_{2g}(\mathbb{Z}))$ for all $g \leq 12$, as well as $\Theta_8^g = M_8(\text{Sp}_{2g}(\mathbb{Z}))$ for all $g \leq 8$. Simpler proof of these results, as well as their extension to all $g$, were then given in [CT], in which the vanishing of $S_k(\text{Sp}_{2g}(\mathbb{Z}))$ is proved for $g > k$ and $k < 13$. Let us mention that dimensions and generators of $S_k(\text{Sp}_{2g}(\mathbb{Z}))$ with $g \leq k \leq 11$, as well as standard $L$-functions of eigenforms, are also given in [CL19] and [CT], completing previous works of several authors, including Ikeda, Igusa, Tsuyumine, Poor-Yuen and Duke-Imamoğlu.

**General notations and terminology**

Let $X$ be a set. We denote by $|X|$ the cardinality of $X$ and by $\mathcal{S}_X$ its symmetric group. Let $k$ be a commutative ring. We denote by $kX$ the free $k$-module over $X$. The elements $x$ of $X$ form a natural $k$-basis of $kX$ that we will often denote by $\nu_x$ to avoid confusions. For $S \subset X$ we also set $\nu_S = \sum_{x \in S} \nu_x$.

If $V$ and $W$ are two $k$-modules, a quadratic map $q : V \to W$ is a map satisfying $q(\lambda v) = \lambda^2 q(v)$ for all $\lambda$ in $k$ and $v$ in $V$, and such that $V \times V \to W$, $(x, y) \mapsto q(x + y) - q(x) - q(y)$, is $k$-bilinear (the associated bilinear form).

A quadratic space over $k$ is a $k$-module $V$ equipped with a quadratic map (usually $k$-valued, but not always). Such a space has an isometry group, denoted $O(V)$, defined as the subgroup of $k$-linear automorphisms $g$ of $V$ with $q \circ g = q$. If $V$ is furthermore a free $k$-module of finite rank, and with $k$-valued quadratic form, the determinant of the Gram matrix of its associated bilinear form in any $k$-basis of $V$ will be denoted by $\det V$ (an element of $k^\times$ modulo squares).

A linking quadratic space (a $q$-module in the terminology of [CL19, Chap. 2]) is a finite quadratic space over $\mathbb{Z}$ whose quadratic form is $\mathbb{Q}/\mathbb{Z}$-valued (or “linking”) and with nondegenerate associated bilinear form. If $A$ is a finite abelian group, the hyperbolic linking quadratic space over $A$ is $H(A) = A \oplus \text{Hom}(A, \mathbb{Q}/\mathbb{Z})$, with the quadratic form $(x, \varphi) \mapsto \varphi(x)$.

Let $L$ be a lattice in the Euclidean space $E$, with inner product $x \cdot y$. The dual lattice of $L$ is the lattice $L^\perp = \{ x \in E \mid x \cdot L \subset \mathbb{Z} \}$. Assume $L$ is integral, that is $L \subset L^\perp$. A root of $L$ is an element $\alpha \in L$ with $\alpha \cdot \alpha = 2$. The roots of $L$ form a (possibly empty) root system $R(L)$ of type ADE and rank $\leq \dim E$: see the beginning of §3 for much more about roots and root systems.

Assume furthermore $L$ is even (that is $x \cdot x$ is in $2\mathbb{Z}$ for all $x$ in $L$). Then we view $L$ as a quadratic space over $\mathbb{Z}$ for the quadratic form $x \mapsto \frac{x^2}{2}, L \to \mathbb{Z}$. Moreover, the finite abelian group $L^\perp/L$ equipped with its nondegenerate $\mathbb{Q}/\mathbb{Z}$-valued quadratic form $x \mapsto \frac{x^2}{2} \mod \mathbb{Z}$ is a linking quadratic space denoted $\text{res } L$ and called the residue of $L$ (often also called the discriminant group or the glue group).

1. The forms $\omega_g$

We fix $\Omega$ a set with 24 elements and as well as an extended binary Golay code $G$ on $\Omega$. This is a 12-dimensional linear subspace of $(\mathbb{Z}/2\mathbb{Z})\Omega$ that is often convenient to view as a subset of $P(\Omega)$, the set of all subsets of $\Omega$. For any element $C$ of $G$ we have $|C| = 0, 8, 12, 16$ or 24. We first recall how to define the Leech lattice using $G$, following Conway in [CS99, Ch. 10, §3].

An octad is an 8-element subset of $\Omega$ belonging to $G$. Their most important property is that any 5 elements of $\Omega$ belong to a unique octad; in particular there are $\binom{24}{5}/\binom{8}{5} = 759$ octads. We view the 24-dimensional space $\mathbb{R}\Omega$ as an Euclidean space with orthonormal (canonical) basis the $\nu_i$ with $i$ in $\Omega$. For $S \subset \Omega$, recall that we set $\nu_S = \sum_{i \in S} \nu_i$. Following Conway, the Leech lattice may be defined as the subgroup of $\mathbb{R}\Omega$ generated by the $\frac{1}{\sqrt{8}} 2\nu_O$ with $O$ an octad, and the $\frac{1}{\sqrt{8}} (\nu_\Omega - 4\nu_i)$ with $i$ in $\Omega$.

The Mathieu group associated to $G$ is the subgroup of $S_\Omega \cong S_{24}$ preserving $G$, and is simply denoted by $M_{24}$. It has $48 \cdot 24!/19! = 244823040$ elements. It acts on $\mathbb{R}\Omega$ (permutation representation), which realizes it a subgroup of $O(\text{Leech})$. We know since Frobenius the cycle decompositions, and cardinality, of all the conjugacy classes of $M_{24}$ acting on $\Omega$ [Fro04, p. 12-13]. For the convenience of the reader they are gathered in Table 1 below, which gives for each cycle shape the quantity $\text{cent} = |M_{24}|/\text{card}$, where $\text{card}$ is the number of elements of this shape in $M_{24}$.\(^1\) This table allows us to compute the average characteristic polynomial of an element in $M_{24}$, and we find:

Fact 1.1. The polynomial $\frac{1}{|M_{24}|} \sum_{\gamma \in M_{24}} \det(t - \gamma)$ is

$$t^{24} - t^{23} - t^{17} + 2 t^{16} - t^{15} - t^{13} + 2 t^{12} - t^{11} - t^9 + 2 t^8 - t^7 - t + 1.$$  

In particular, the space of $M_{24}$-invariant alternating $g$-multilinear forms on $\mathbb{Q}\Omega$ has dimension 2 for $g = 8, 12, 16$. We will now exhibit concrete generators for the $M_{24}$-invariants in each $\Lambda^g \mathbb{Q}\Omega$. We start with some general preliminary remarks.

\(^1\)We write this number in the form $n/2$ in the five cases where there are more than one conjugacy class of the given shape. In these five cases, there are exactly two conjugacy classes, each of which containing $|M_{24}|/n$ elements.
Fact 1.2. It is straightforward to check the following fact: 

Then \( \sigma_s \) is a nonzero \( G \)-invariant in \( \Lambda^g Q X \). Both \( \pm \beta_s \) and \( \pm \sigma_s \) only depend on \( S \), we denote them respectively by \( \beta_S \) and \( \sigma_S \). We also set \( \beta_0 = \sigma_0 = 1 \). It straightforward to check the following fact:

**Fact 1.2.** If a group \( G \) acts on the finite set \( X \), and if \( S_g \) is a set of representatives for the \( G \)-orbits of \( G \)-orientable subsets of \( X \) with \( g \) elements, then the \( \sigma_S \) with \( S \) in \( S_g \) are a \( \mathbb{Q} \)-basis of the \( G \)-invariants in \( \Lambda^g Q X \).

The following lemma could probably be entirely deduced from Conway’s results in [CS99, Chap. 10 §2]. We will rather use Facts 1.1 & 1.2 to prove it. Recall that we identify \( \mathcal{P}(\Omega) \) with \( (\mathbb{Z}/2\mathbb{Z})^\Omega \). In particular for \( S_1, S_2 \) in \( \mathcal{P}(\Omega) \) we have \( S_1 + S_2 = (S_1 \cup S_2) \setminus (S_1 \cap S_2) \).

**Lemma 1.3.** Let \( S \) be a subset of \( \Omega \). Then \( S \) is \( M_{24} \)-orientable if, and only if, it is of the form \( C + P \), with \( C \) in \( \mathcal{G} \) and either \( |P| \leq 1 \), or \( |P| = 2 \) and \( |P \cap C| = 1 \).

**Proof.** The elements of \( \mathcal{G} \) have size 0, 8, 12, 16 or 24. The \( C + P \) with \( C \) in \( \mathcal{G} \) and \( P \) a point thus have size 1, 7, 9, 11, 13, 15, 17 or 23, and the \( C + P \) with \( |P| = 2 \) and \( |C \cap P| = 1 \) have size 8, 12 or 16. If we can show that all of those subsets are \( M_{24} \)-orientable, then Facts 1.1 and 1.2 will not only prove the lemma, but also that there is a single \( M_{24} \)-orbit of subsets of each of these 16 types.

Fix \( C \) in \( \mathcal{G} \), denote by \( G_C \subseteq M_{24} \) its stabilizer and by \( I_C \) the image of the natural morphism \( G_C \rightarrow \mathcal{G}_C \). If we have \( C = 0 \) or \( C = \Omega \), then \( C \) is \( M_{24} \)-orientable (\( M_{24} \) is even a simple group). If \( C \) is an octad, Conway showed that \( I_C \) is the full

| shape | 1^8 2^8 | 2^{12} | 1^6 3^6 | 3^8 | 2^4 4^4 | 1^4 2^2 4^4 | 4^6 | 1^4 5^4 | 1^2 2^2 3^2 6^2 | 6^4 |
|-------|---------|--------|---------|------|--------|--------|------|--------|-----------------|-----|
| cent  | 21504   | 7680   | 1080    | 504  | 384    | 128    | 96   | 60     | 24              | 24  |

| shape | 1^3 3^3 | 1^2 2 4^2 | 2^2 10^2 | 1^2 11^2 | 2^4 6 12 | 2^2 12 | 12^2 | 12 7 14 | 13 5 15 | 321 | 1 23 |
|-------|---------|-----------|----------|----------|----------|-------|------|---------|--------|-----|-----|
| cent  | 42/2    | 16        | 20       | 11       | 12       | 12    | 14/2 | 15/2    | 21/2   | 23/2 |

**Table 1.** The cycle shape of the nontrivial elements of \( M_{24} \).
alternating group of $C$, so that octads are $M_{24}$-orientable. As $\Omega$ is $M_{24}$-orientable, it follows that complements of octads are $M_{24}$-orientable as well. If $C$ is a dodecad, Conway showed that $I_C$ is a Mathieu permutation group $M_{12}$ over $C$, hence in the alternating group of $C$ as well (again, it is even a simple group), so that dodecads are $M_{24}$-orientable.

Fix furthermore a subset $P$ of $\Omega$, assuming first $|P| \leq 3$, and consider the subset $C + P$ in $P(\Omega)$. If $\gamma$ in $M_{24}$ preserves $C + P$, we have

$$C + \gamma(C) = P + \gamma(P).$$

The left-hand side is an element in $G$, hence so is $P + \gamma(P)$. But this last subset has at most 6 elements, hence must be 0. It follows that the stabilizer of $C + P$ is the subgroup of $G_C$ stabilizing $P$. If we assume furthermore either $|P| = 1$, or $|P| = 2$ and $|P \cap C| = 1$, we deduce that the $M_{24}$-orientability of $C$ implies that of $C + P$, and we are done.

The code $G$ itself also embeds in $O(\mathbb{R} \Omega)$ by letting the element $S$ of $G$ act on $\nu_i$ by $-1$ if $i$ is in $S$, 1 otherwise. As shown by Conway [CS99, Chap. 10, §3, Thm. 26], this is also a subgroup of $O(\text{Leech})$, obviously normalized by $M_{24}$. The subgroup of $O(\text{Leech})$ generated by $G$ and $M_{24}$ is denoted by $N$ or $2^{12}M_{24}$ by Conway. It will play a role in the proof of the following proposition.

**Proposition 1.4.** For all $g$ in $\{0, 8, 12, 16, 24\}$, the line of $O(\text{Leech})$-invariants in $\Lambda^g\text{Leech} \otimes \mathbb{Q}$ is generated by $\sigma_C$, where $C$ is any element of $G$ with $|C| = g$.

**Proof.** Fix $g \geq 0$ and set $V_g = \Lambda^g \mathbb{Q} \Omega$. We have the trivial inclusions

$$V_g^{O(\text{Leech})} \subset V_g^N \subset V_g^{M_{24}},$$

the dimension of the left-hand side being given by (1), and that of the right-hand side by Fact 1.1. We will show that $V_g^N$ is non-zero only for $g$ in $\{0, 8, 12, 16, 24\}$, and that in these cases $V_g^N$ is generated by $\sigma_C$ for $C \in G$ with $|C| = g$ (recall from the proof of Lemma 1.3 that $M_{24}$ acts transitively on the set of such $C$’s).

Let $S$ be an $M_{24}$-orientable subset of $\Omega$ of the form $S = C + P$ as in the statement of Lemma 1.3. If Conway’s group $N$ fixes $\sigma_S$, then the element $\beta_S$ in (3) has to be fixed by the action of $C$. By definition, this element of $G$ acts on $\beta_S$ by multiplication by $(-1)^{|S \cap C|}$, so we must have $|S \cap C| \equiv 0 \mod 2$, hence $P = 0$ or $|P| = 1$ and $P \cap C = \emptyset$. In the latter case, the element $C' = \Omega \sim C$ of $G$ contains $P$, so it maps $\beta_S$ to $-\beta_S$ and the basis $\sigma_S$ of $V_g^{M_{24}}$ is not fixed by $N$. We have proved $\dim V_g^N \leq 1$ for $g$ in $\{0, 8, 12, 16, 24\}$, and $V_g^N = 0$ otherwise. Fix now $C$ in $G$ and set $g = |C|$. For all $C'$ in $G$ we have $|C \cap C'| \equiv 0 \mod 2$. This shows that $N$ acts trivially on $\sigma_C$: we have proved $V_g^N = \mathbb{Q} \sigma_C$. \hfill $\square$

The inner product $\text{Leech} \times \text{Leech} \rightarrow \mathbb{Z}$, $(x, y) \mapsto x \cdot y$, induces for each integer $g \geq 0$ an $O(\text{Leech})$-equivariant isomorphism $\Lambda^g \text{Leech} \otimes \mathbb{Q} \rightarrow \text{Hom}(\Lambda^g \text{Leech}, \mathbb{Q})$. 

This isomorphism sends the element \( v_i \wedge v_j \wedge \cdots \wedge v_g \), with \( v_i \) in Leech for all \( i \), to the alternating \( g \)-multilinear form on Leech defined by \( (x_1, \ldots, x_g) \mapsto \det(x_i \cdot v_j)_{1 \leq i, j \leq g} \).

**Definition 1.5.** The element \( \sigma_C \), where \( C \) is any element of \( G \) with \( |C| = g \), viewed as above as an alternating \( g \)-multilinear form on Leech, will be denoted by \( \omega_g \). It is well defined up to a sign, nonzero, and \( O(\text{Leech}) \)-invariant.

Note that by definition, we have \( \omega_0 = 1 \), and \( \pm \omega_{24} \) is the determinant taken in the canonical basis \( v_i \) of \( \mathbb{Q} \Omega \), or equivalently, in a \( \mathbb{Z} \)-basis of Leech as the latter is unimodular.

For the sake of completeness, we end this section with the determination of the ring structure of the \( O(\text{Leech}) \)-invariants in the exterior algebra \( \Lambda \text{Leech} \otimes \mathbb{Q} \). Denote by \( m_g \) the number of \( g \)-element subsets of \( G \). We have \( m_0 = m_{24} = 1 \), \( m_8 = m_{16} = 759 \) and \( m_{12} = 212^2 - 2 \cdot 2 \cdot 759 = 2576 \). Let us simply write \( \sigma_g \) for the element \( \pm \sigma_C \) with \( C \) in \( G \) and \( |C| = g \).

**Proposition 1.6.** We have \( \sigma_8 \wedge \sigma_8 = \pm 30 \sigma_{16} \) and \( \sigma_g \wedge \sigma_{24-g} = \pm m_g \sigma_{24} \) for all \( g \) in \( \{0, 8, 12, 16, 24\} \).

**Proof.** Fix \( C \subset \Omega \) of size \( g \), denote by \( C' \) its complement, and fix \( c \) and \( c' \) respective orientations of \( C \) and \( C' \). The stabilizers of \( C \) and \( C' \) in \( M_{24} \) coincide, call them \( G \). We have \( \sigma_C \wedge \sigma_{C'} = \pm \sum_{\gamma, \gamma' \in M_{24}/G} \gamma(\beta_c) \wedge \gamma'(\beta_c') \). An element in this sum is nonzero if, and only if, we have \( \gamma(C) \cap \gamma'(C') = \emptyset \), or equivalently \( \gamma'(C) = \gamma(C) \), i.e. \( \gamma = \gamma' \). We conclude the second assertion by the \( M_{24} \)-orientability of \( \Omega \) and the equality \( |M_{24}/G| = m_g \).

We now determine \( \sigma_8 \wedge \sigma_8 \). Let \( T \) be the set of triples \((O_1, O_2, O_3)\) where the \( O_i \) are octads satisfying \( O_1 \coprod O_2 \coprod O_3 = \Omega \) (ordered trios). By [CS99, Chap. 10, §2, Thm. 18], \( M_{24} \) acts transitively on \( T \) and we have \( |T| = 30 m_8 \). Fix \((O_1, O_2, O_3)\) in \( T \), an orientation \( o_i \) of each \( O_i \), and denote by \( S_i \) the stabilizer of \( O_i \) in \( M_{24} \). As octads are \( M_{24} \)-orientable, for any \( \gamma_1, \gamma_2, \gamma_3 \) in \( M_{24} \) the element \( t(\gamma_1, \gamma_2, \gamma_3) = \gamma_1 \beta_{o_1} \wedge \gamma_2 \beta_{o_2} \wedge \gamma_3 \beta_{o_3} \) only depends on the \( \gamma_i \) modulo \( S_i \). We have

\[
\sigma_{o_1} \wedge \sigma_{o_2} \wedge \sigma_{o_3} = \sum_{\gamma_i \in M_{24}/S_i} t(\gamma_1, \gamma_2, \gamma_3).
\]

Observe that \( t(\gamma_1, \gamma_2, \gamma_3) \) is nonzero if and only if the three octads \( \gamma_i(O_i) \), \( \gamma_j(O_j) \) and \( \gamma_3(O_3) \) are disjoint, in which case we have \( t(\gamma_1, \gamma_2, \gamma_3) = \pm t(1, 1, 1) = \pm \sigma_{24} \).

There are thus exactly \(|T|\) nonzero terms \( t(\gamma_1, \gamma_2, \gamma_3) \) in the sum (4). Fix such a nonzero term. The transitivity of \( M_{24} \) on \( T \) shows the existence of \( \gamma \) in \( M_{24} \) with \( \gamma \gamma_i \in S_i \) for each \( i \). As \( \Omega \) is \( M_{24} \)-orientable, we have

\[
t(\gamma_1, \gamma_2, \gamma_3) = \gamma t(\gamma_1, \gamma_2, \gamma_3) = t(\gamma \gamma_1, \gamma \gamma_2, \gamma \gamma_3) = t(1, 1, 1).
\]

(“the sign is always +1’’). We have proved \( \sigma_8 \wedge \sigma_8 \wedge \sigma_8 = \pm |T| \sigma_{24} \). As \( \sigma_8 \wedge \sigma_8 \) must be a multiple of \( \sigma_{16} \), we conclude by the identity \( \sigma_8 \wedge \sigma_{16} = \pm m_8 \sigma_{24} \). \( \square \)
2. Fixed point lattices of some prime order elements in \( M_{24} \)

We keep the notations of §1, and fix an element \( c \) in \( M_{24} \) of order \( p \), with \( p \) an odd prime. We are interested in the fixed points lattice

\[
Q = \{ v \in \text{Leech} \mid cv = v \},
\]

and in its orthogonal \( Q^\perp \) in Leech. Let \( F \subset \Omega \) the subset of fixed points of \( c \) and \( Z \subset P(\Omega) \) the set of supports of its \( p \)-cycles. We have \( a + pb = 24 \) with \( a = |F| \), \( b = |Z| \), and \( b \geq 1 \). Those lattices are special cases of those considered in [HL90].

We denote by \( I_n \otimes \mathbb{Z}/p\mathbb{Z} \) the linking quadratic space \((\mathbb{Z}/p\mathbb{Z})^n \) equipped with \( \frac{1}{p}Z/\mathbb{Z}_p \)-valued quadratic form \( \frac{1}{p} \sum_{i=1}^n x_i^2 \). If \( V \) is a quadratic space, we denote by \(-V \) the quadratic space with same underlying group but opposite quadratic form.

**Lemma 2.1.** The lattices \( Q \) and \( Q^\perp \) are even, without roots, of respective ranks \( a + b \) and \( (p-1)b \), and we have \( \text{res} \, Q \cong I_6 \otimes \mathbb{Z}/p\mathbb{Z} \) and \( \text{res} \, Q^\perp \cong -\text{res} \, Q \).

**Proof.** It is clear that \( Q \) and \( Q^\perp \) are even and without roots, as so is Leech. We also have \( p \) Leech \( \subset Q \oplus Q^\perp \) because of the identity \( 1+c+c^2+\cdots+c^{p-1} \in p+(c-1)\mathbb{Z}[c] \). As Leech is unimodular and \( p \) is odd, we deduce that both \( Q \) and \( Q^\perp \) are odd. It is thus enough to prove both assertions about \( \text{res} \, Q \) and \( \text{res} \, Q^\perp \) after inverting \( 2 \). As \( \Omega \) is the disjoint union of 3 octads, note that the 24 elements \( \sqrt{2} \nu_i \) with \( i \in \Omega \) form an orthogonal \( \mathbb{Z}[\frac{1}{2}] \)-basis of Leech[\( \frac{1}{2} \)].

On the one hand, this implies that the \( a \) elements \( \sqrt{2} \nu_i \) with \( i \in F \), and the \( b \) elements \( \sqrt{2} \nu_Z \) with \( Z \in Z \), form an orthogonal \( \mathbb{Z}[\frac{1}{2}] \)-basis of \( Q[\frac{1}{2}] \). For the quadratic form \( q(x) = \frac{x^2}{2} \) and \( S \subset \Omega \), we have \( q(\sqrt{2} \nu_S) = |S| \); we have proved the assertion about \( \text{res} \, Q \).

On the other hand, this also shows that \( Q^\perp[\frac{1}{2}] \) is the submodule of Leech[\( \frac{1}{2} \)] consisting of the \( \sum_{i \in \Omega \setminus F} x_i \sqrt{2} \nu_i \) with \( x_i \in \mathbb{Z}[\frac{1}{2}] \) satisfying \( \sum_{i \in Z} x_i = 0 \) for any \( Z \) in \( Z \). In other words \( \frac{1}{\sqrt{2}} Q^\perp[\frac{1}{2}] \) is isomorphic to the root lattice \( A_{p-1}^b \) over \( \mathbb{Z}[\frac{1}{2}] \). It follows that \( \text{res} \, Q^\perp[\frac{1}{2}] \) is isomorphic to \(-I_b \otimes \mathbb{Z}/p\mathbb{Z} \). (See also [CL19, Prop. B.2.2 (d)] for a more conceptual proof of \( \text{res} \, Q^\perp \cong -\text{res} \, Q \)).

By Table 1, there are 8 conjugacy classes of elements of odd prime order in \( M_{24} \), with respective shape \( 3^8 \), \( 1^6 \cdot 3^6 \), \( 1^4 \cdot 5^4 \), \( 1^3 \cdot 7^3 \) (two classes), \( 1^2 \cdot 11^2 \) and 1 23 (two classes). For our applications we are looking for cases \( 1^a \cdot p^b \) with \( a+b \) in \( \{8, 12, 16\} \) and \( Q \) orientable. Only the first three conjugacy classes just listed meet the first condition, and the class with shape \( 3^8 \) does not meet the second. Indeed, in this case, the description above of \( Q[\frac{1}{2}] \) shows \( x \cdot x \equiv 0 \mod 3 \) for all \( x \in Q \). This implies that \( \frac{1}{\sqrt{3}} Q \) is an even unimodular lattice of rank 8, necessarily isomorphic to \( E_8 \), hence non-orientable. In §3, we will check that the lattice \( Q \) is actually orientable for the two remaining classes \( 1^6 \cdot 3^6 \) and \( 1^4 \cdot 5^4 \), and has the following properties:

**Proposition 2.2.** Let \( g \) be 8, 12 or 16. Up to isometry, there is a unique even lattice \( Q_g \) of rank \( g \) without roots and with residue isomorphic to \( I_4 \otimes \mathbb{Z}/5\mathbb{Z} \) (case
In the following lemmas, there are two following lemmas). Proposition 2.2 (this proposition will only be used at the end, and not in the proof of the two following lemmas).

Recall that a dodecad is an element of \( G \) with 12 elements. Moreover, a subset \( S \subset \Omega \) with \(|S| = 4\) (resp. \(|S| = 6\)) is called a tetrad (resp. a hexad). Following Conway, we will also say that an hexad is special if it is contained in an octad, and umbral otherwise. The umbral hexads are obtained as follows: choose 5 points in an octad and 1 in its complement.

**Lemma 2.3.**

(i) A tetrad \( T \) is contained in exactly 5 octads.

(ii) If \( \gamma \) in \( M_{24} \) is an element of order 5 whose set of fixed points is a tetrad \( T \), then the 5 octads containing \( T \) are permuted transitively by \( \gamma \), and each of them intersects each orbit of \( \gamma \) at exactly one point.

(iii) An umbral hexad \( U \) is contained in exactly 18 dodecads; these 18 dodecads are permuted transitively by the stabilizer of \( U \) in \( M_{24} \).

(iv) Let \( \gamma \) in \( M_{24} \) be an element of order 3 with 6 fixed points. The set \( U \) of fixed points of \( \gamma \) is an umbral hexad, and each dodecad containing \( U \) intersects each orbit of \( \gamma \) at exactly one point. Moreover, the stabilizer \( G_U \) of \( U \) in \( M_{24} \) coincides with the normalizer of \( \langle \gamma \rangle \) in \( M_{24} \), and the natural map \( G_U \to S_U \) is surjective with kernel \( \langle \gamma \rangle \).

Most of these statements are certainly well-known. We will explain how to deduce them from the exposition of Conway in [CS99, Chap. 10 §2].

**Proof.** Proof of (i). Recall that any 5-element subset of \( \Omega \) is contained in a unique octad. This shows that if \( T \) is a tetrad, its complement is the disjoint union of 5 other tetrads \( T_i \), uniquely determined by the property that \( T \cup T_i \) is an octad for each \( i \) (these six tetrads, namely \( T \) and the \( T_i \), form a sextet in the sense of Conway).

Proof of (ii). The element \( \gamma \) permutes the five \( T_i \) above since we have \( \gamma(T) = T \). Assume there is some \( i \), some \( x \) in \( T_i \), and \( k \) in \( (\mathbb{Z}/5\mathbb{Z})^\times \), with \( \gamma^k(x) \in T_i \). Then \( \gamma^k(T \cup T_i) \) is the unique octad containing \( T \cup \gamma^k(x) \), hence equals \( T \cup T_i \), and so we have \( \gamma^k(T_i) = T_i \). But this implies \(|T_i| \geq 5\): a contradiction.

Proof of the first assertion of (iii). Conway shows loc. cit. that \( M_{24} \) acts transitively on the octads, on the dodecads, and 6 + 1 transitively on an octad and its complement, hence transitively on the umbral (resp. special) hexads as well. There are thus \( 759 \cdot \binom{8}{6} = 21252 \) special hexads in \( \Omega \), and \( \left( \binom{24}{6} \right) - 21252 = 113344 \) umbral hexads. There are also \( 2^{12} - 2 \cdot 759 = 2576 \) dodecads. Fix a dodecad \( D \). For any octad \( O \), we have \(|D + O| \in \{0, 8, 12, 16, 24\}\) since \( D + O \) is in \( G \), and \(|D + O| = 20 - 2|D \cap O|\), so \(|D \cap O| \) is in \( \{2, 4, 6\} \). Therefore the octad
In order to prove the second assertion in (iii), we show that the pairs \((U, D)\) as above are permuted transitively by \(M_{24}\). Fix a dodecad \(D\). It is enough to show that the stabilizer \(H\) of \(D\) in \(M_{24}\) permutes transitively the umbral hexads of \(D\). But \(H\) is a Mathieu group \(M_{12}\) and is sharply 5 transitive on \(D\) by Conway. In particular, \(H\) permutes transitively the special hexads of \(D\). Fix \(S \subset D\) a special hexad and denote by \(S'\) its complement in \(D\). The stabilizer \(H_S\) of \(S\) in \(H\) acts faithfully both on \(S\) and \(S'\), and 5 transitively on \(S\), by the sharp 5 transitivity of \(H\) on \(D\). The two projections of the natural morphism \(H_S \to \mathfrak{S}_S \times \mathfrak{S}_{S'}\) are thus injective, and the first one is surjective: they are both bijective. (This is of course compatible with the equality \([M_{12}] / 132 = 720\).) By numbering \(S\) and \(S'\), we obtain two isomorphisms \(H_S \to \mathfrak{S}_6\). We claim that they differ by an outer automorphism of \(\mathfrak{S}_6\). Indeed, an element of \(M_{24}\) of order two with at least 1 fixed point on \(\Omega\) has actually 8 fixed points by Table 1, which must form an octad (see the beginning of §2.2 in [CS99, Ch. 10]). The group \(H_S\) contains an element of order 2 with 4 fixed points in \(S\), but its 4 remaining fixed points cannot lie in \(D\) because no octad is contained in \(D\). This proves the claim. It follows that the stabilizer in \(H_S\) of a point \(P\) of \(S\) (isomorphic to \(\mathfrak{S}_5\)) acts transitively on \(S'\), hence on the set of umbral hexads in \(D\) containing \(S \setminus P\). Together with the fact that \(H\) acts 5 transitively on \(D\), this shows that \(H\) acts transitively on the umbral hexads in \(D\).

Proof of (iv). If \(O\) is an octad containing \(U\), necessarily unique, we have \(\gamma(O) = O\), and so \(\gamma\) stabilizes the two-element set \(O \setminus U\) without fixed point: a contradiction. So \(U\) is an umbral hexad. For any \(u\) in \(U\), there is a unique octad \(O_u\) containing \(U \setminus \{u\}\). The six \(O_u\), and the six 3-element sets \(Z_u = O_u \setminus U\) are thus preserved by any element of \(M_{24}\) fixing \(U\) pointwise. In particular, the \(Z_u\) are the supports of the 3-cycles of \(\gamma\). The assertion about dodecads follows as we already explained in the proof of (iii) that any octad \(O\) containing five points of a dodecad \(D\) satisfies \(|O \cap D| = 6\). This also shows that the pointwise stabilizer of \(U\) in \(M_{24}\) is \(\langle \gamma \rangle\): a non trivial element of \(M_{24}\) with at least 7 fixed points has shape \(1^8 2^8\) by Table 1, and as recalled above the set of its fixed points is an octad. Let now \(G_U\) be the stabilizer of \(U\) in \(M_{24}\), and \(H\) the normalizer of \(\langle \gamma \rangle\). We have \(H \subset G_U\). We know that \(G_U\) has \(|M_{24}| / 113344 = 2160\) elements. Table 1 also shows that the centralizer of \(\gamma\) has 1080 elements, and that its normalizer contains an element sending \(\gamma\) to \(\gamma^{-1}\), so we have \(H = G_U\). We have seen that the kernel of
Lemma 2.4.  
(i) Assume $c$ has shape $1^4 5^4$, so that $Q$ and $Q^\perp$ have respective ranks 8 and 16, and fix $v \in Q^8$ and $u \in (Q^\perp)^{16}$ two $\mathbb{Z}$-bases of these respective lattices. Then we have $\omega_8(v) = \pm 5$ and $\omega_{16}(u) = \pm 5$.

(ii) Assume $c$ has shape $1^6 3^6$, so that $Q$ has rank 12, and fix $v \in Q^{12}$ a $\mathbb{Z}$-basis of $Q$. Then we have $\omega_{12}(v) = \pm 18$.

Proof. We first show $\omega_8(v) = \pm 5$ in (i) and $\omega_{12}(v) = \pm 18$ in (ii). If $v' = (v'_1, \ldots, v'_g)$ is any $Q$-basis of $Q \otimes \mathbb{Q}$, we have $\omega_g(v') = \det_v(v') \omega_g(v)$, and $|\det_v(v')|$ is the covolume of the lattice $\sum_i Zv'_i$ divided by the covolume of $Q$ (that is, by 25 or 27).

Fix from now on a basis $v'$ made of the $\sqrt{2} \nu_i$ with $i \in F$, and the $\sqrt{2} \nu_Z$ with $Z$ in $Z$. We have $\det_v(v') = \pm 2^{g/2}$, so we need to prove that $2^{-g/2} \omega_g(v') = \pm 5$ in the case $g = 8$, and $\pm 18$ in the case $g = 12$.

By Definition 1.5, $\omega_g(v')$ is a sum of terms of the form $\det(v'_i \cdot x_j)_{1 \leq i,j \leq g}$ where $\{x_1, \ldots, x_g\}$ runs over all the possible elements $C$ of $G$ of size $g$, numbered in an $M_{24}$-equivariant way. For such a determinant to be nonzero, each linear form $v \mapsto v \cdot x_i$ has to be nonzero on $Q$: the subset $C$ has thus to contain all the elements of $F$, and a point in each $Z$ in $Z$. In other words, such a $C$ has to meet each of the $g$ orbits of $c$ in exactly one point. Denote by $C(c)$ the set of elements of $G$ of size $g$ with this property. For all $C = \{x_1, \ldots, x_g\}$ in $C(c)$ we have

1. $\det(v'_i \cdot x_j)_{1 \leq i,j \leq g} = \pm 2^{g/2}$.

By Lemma 2.3 (ii) and (iv), the set $C(c)$ consists of 5 octads (resp. 18 dodecads) if $c$ has shape $1^4 5^4$ (resp. $1^6 3^6$), and the normalizer $G$ of $\langle c \rangle$ in $M_{24}$ permutes $C(c)$ transitively. If we fix $C = \{x_1, \ldots, x_g\}$ in $C(c)$, we may thus find a $|C(c)|$-element subset $\Gamma \subseteq G$ with

$$\omega_g(v') = \pm \sum_{\gamma \in \Gamma} \det(v'_i \cdot x_j)_{1 \leq i,j \leq g}.$$

We claim that the $|\Gamma|$ determinants above are equal. This will show $\omega_g(v') = \pm |C(c)|2^{g/2}$ by (5). For any $\gamma \in G$ we have

$$\det(v'_i \cdot x_j)_{1 \leq i,j \leq g} = \det(v_i^{-1} v'_i \cdot x_j)_{1 \leq i,j \leq g} = \det \gamma^{-1} \det(v'_i \cdot x_j)_{1 \leq i,j \leq g}.$$

As $Q$ is orientable by Lemma 2.1 and Proposition 2.2, we have $\det \gamma|Q = 1$, and we are done. We may actually avoid the use of these lemmas and proposition as follows. If $c$ has shape $1^4 5^4$, we may choose $\Gamma = \langle c \rangle$ by Lemma 2.3 (ii), and we clearly have $\gamma|Q = \text{id}$. If $c$ has shape $1^6 3^6$, the proof of Lemma 2.3 (iv) defines a natural $G$-equivariant bijection $u \mapsto Z_u$ between $U$ and $Z$. For any $\gamma \in G$ we have thus $\det \gamma|Q = \epsilon^2 = 1$, where $\epsilon$ is the signature of the image of $\gamma$ in $\mathfrak{S}_U$.

We now prove $\omega_{16}(u) = \pm 5$ in (i). Observe first that for any oriented octad $(O, o)$, there is a sign $\epsilon$ such that for all $u'_1, \ldots, u'_{16}$ in $Q \Omega$ we have

$$\omega_{16}(u'_1, \ldots, u'_{16}) = \epsilon \omega_{24}((\sigma_o \wedge u'_1 \wedge u'_2 \wedge \ldots \wedge u'_{16})$$. 

$G_U \to \mathfrak{S}_U$ is $\langle \gamma \rangle$, and we conclude that this morphism is surjective by the equality $2160/3 = 6!$. □
Indeed, the alternating 16-form on the right is $O(\text{Leech})$-invariant, as both $\sigma_o$ and $\omega_{24}$ are, so it is proportional to $\omega_{16}$. But if $\{u'_1, \ldots, u'_{16}\}$ is a 16-element subset of $G$, both sides are equal to $\pm 1$, and we are done.

Choose a basis $u'$ of $Q^\perp \otimes \mathbb{Q}$ made of 16 elements of the form $\sqrt{2}(\nu_i - \nu_{c(i)})$ with $i$ in $\Omega \setminus F = \bigcup_{Z \in \mathcal{Z}} Z$ (i.e. choose 4 elements $i$ in each $Z \in \mathcal{Z}$). Comparing covolumes as in the first case of the proof, we have to show $\omega_{16}(u') = \pm 5 \cdot 2^5$. Apply Formula (6) to $u' = (u'_1, \ldots, u'_{16})$. If $\gamma(O)$ is an octad such that $\gamma(\beta_O) \land u'_1 \land u'_2 \land \cdots \land u'_{16}$ is nonzero, that octad meets at most once each $u$ in $\Omega$. By Lemma 2.3 (i) and (ii), there are 5 such octads, permuted transitively by $c$. We may choose $O$ to be one of them. We then have

$$\omega_{16}(u'_1, \ldots, u'_{16}) = \epsilon \sum_{k \in \mathbb{Z}/|\mathcal{Z}|} \omega_{24}(\epsilon^k \beta_o \land u'_1 \land u'_2 \land \cdots \land u'_{16}).$$

Now $c$ preserves $Q^\perp$ and has determinant 1 on it (being of order 5), so we have $u'_1 \land \cdots \land u'_{16} = c^k(u'_1 \land \cdots \land u'_{16})$ and the sum above is 5 times $\omega_{24}(\beta_o \land u'_1 \land u'_2 \land \cdots \land u'_{16})$ by $c$-invariance of $\omega_{24}$. An easy computation shows that we have $\omega_{24}(\beta_o \land u'_1 \land u'_2 \land \cdots \land u'_{16}) = \pm 2^9$. 

We are now able to prove Theorem 2, assuming Proposition 2.2.

**Proof.** (Proposition 2.2 implies Theorem 2) Let $L_g$ be the set of sublattices of Leech isometric to $Q_g$. This set is nonempty by Lemma 2.1 and we fix one of its elements, that we denote $Q_g$. By Proposition 2.2, $O(\text{Leech})$ acts transitively on $L_g$, so we may find an $n_g$-element subset $\Gamma \subset O(\text{Leech})$ with $L_g = \Gamma \cdot Q_g$.

Fix a $\mathbb{Z}$-basis $u_1, \ldots, u_g$ of $Q_g$, and denote by $2n$ its Gram matrix. The $n$-th Fourier coefficient of $F_g$ is the sum, over all the $g$-uples $(v_1, \ldots, v_g)$ of elements of Leech with $2n = (v_i \cdot v_j)\leq i,j \leq g$, of $\omega_g(v_1, \ldots, v_g)$. There are exactly $n_g|O(Q_g)|$ such $g$-uples, namely the $(\gamma \gamma' u_1, \ldots, \gamma \gamma' u_g)$ with $\gamma \in \Gamma$ and $\gamma' \in O(Q_g)$. The $O(\text{Leech})$-invariance of $\omega_g$, the trivial equality $\omega_g(\gamma \gamma' u_1, \ldots, \gamma \gamma' u_g) = (\det \gamma') \omega_g(u_1, \ldots, u_g)$ for $\gamma'$ in $O(Q_g)$, and the property $\det \gamma' = 1$ (as $Q_g$ is orientable), imply that the $n$-th Fourier coefficient of $F_g$ is $n_g|O(Q_g)|\omega_g(u_1, \ldots, u_g)$. We conclude by Lemma 2.4. 

3. Properties of the lattices $Q_g$

The aim of this section is to prove Proposition 2.2. We make first some preliminary remarks about root lattices and their sublattices.

Let $R$ be a root system in the Euclidean space $V$. We will follow Bourbaki’s definitions and notations in [Bou68, Chap. VI] and assume furthermore that we have $\alpha \cdot \alpha = 2$ for all $\alpha$ in $R$. In particular, each irreducible component of $R$ is of type $A_l$ ($l \geq 1$), $D_l$ ($l \geq 3$) or $E_l$ ($l = 6, 7, 8$), and $R$ is identified to its dual root
system, with $\alpha^\vee = \alpha$ for all roots $\alpha$. We denote by $Q(R)$ the even lattice of $V$ generated by $R$ and by $P(R)$ the dual lattice $Q(R)^\perp$, so that we have
\[
\text{res } Q(R) = P(R)/Q(R).
\]
It is well known that the trivial inclusion $R \subset R(Q(R))$ is an equality. We will simply denote by $A_l$, $D_l$ and $E_l$ for $Q(R)$ when $R$ is $A_l$, $D_l$ or $E_l$ respectively. The Weyl group of $R$ will be denoted by $W(R)$, and the orthogonal group of $Q(R)$ by $A(R)$. The group $W(R)$ is the subgroup of $A(R)$ generated by the orthogonal symmetries $s_\alpha(x) = x - (\alpha \cdot x)\alpha$ with $\alpha \in R$, hence acts trivially on $\text{res } Q(R)$. It permutes simply transitively the positive root systems $R_+$ of $R$. Fix such an $R_+$, and denote by $\{\alpha_i \mid i \in I\}$ its simple roots. The $\alpha_i$ form a $\mathbb{Z}$-basis of $Q(R)$, whose dual basis $\varpi_i$ (the fundamental weights) is thus a $\mathbb{Z}$-basis of $P(R)$. The Weyl vector $\rho$ associated to $R_+$ is the half-sum of elements of $R_+$, it satisfies $\rho = \sum_{i \in I} \varpi_i$.

Assume now $R$ is irreducible of rank $\dim V = |I| = l$; we will always identify the set $I$ with $\{1, \ldots, l\}$ as in Bourbaki. The highest positive root is the unique element $\tilde{\alpha}$ in $R_+$ satisfying $\alpha \cdot \varpi_i \leq \tilde{\alpha} \cdot \varpi_i$ for all $i$ in $I$ and $\alpha$ in $R$. There are unique integers $n_i > 0$ for $i = 1, \ldots, l$ with $\tilde{\alpha} = \sum_{i=1}^l n_i \alpha_i$. Let $h(R)$ be the Coxeter number of $R$ [Bou68, Chap. V & VI], for $h = h(R)$ we have
\[
|R| = lh, \quad n_1 + n_2 + \ldots + n_l = h - 1 \quad \text{and} \quad \rho \cdot \rho = \frac{l}{12} h(h+1).
\]
Indeed, the first equality is [Bou68, Chap. V §6 Thm. 1] and the second is [Bou68, Chap. VI §1 Prop. 31] (see also [Kos59, Theorem 8.4]). The last equality may either be checked case by case, using the ADE classification, or deduced from [Kos59].

Recall $h(A_l) = l + 1$, $h(D_l) = 2l - 2$, $h(E_6) = 12$, $h(E_7) = 18$ and $h(E_8) = 30$. Following Borel-de Siebenthal and Dynkin, the sublattice
\[
BS_i(R) = \{x \in Q(R) \mid x \cdot \varpi_i \equiv 0 \text{ mod } n_i\}
\]
is the root lattice $Q(R_i)$ where $R_i$ is the root system of $V$ having as a set of simple roots $-\tilde{\alpha}$ and the $\alpha_j$ with $j \neq i$ [Bou68, Chap. VI, §4, Exercise 4]. The Dynkin diagram of $R_i$ is thus obtained by removing $\alpha_i$ from the extended Dynkin diagram of $R$. We clearly have $W(R_i) \subset W(R)$. The fundamental weights of $R_i$ with respect to the simple roots above are $-\frac{1}{n_i} \varpi_i$ and the $\varpi_j - \frac{n_j}{n_i} \varpi_i$ for $j \neq i$; in particular, the corresponding Weyl vector of $R_i$ is $\rho - \frac{h}{n_i} \varpi_i$.

1 We may argue as follows. Recall that the height of the positive root $\alpha \in R_+$ is $h(\alpha) = \rho \cdot \alpha$. We thus have $2 \rho \cdot \rho = \sum_{\alpha \in R_+} h(\alpha)$. By Bourbaki’s theory of the canonical bilinear form [Bou68, Ch. VI §1.12] we also have $h(R) \rho \cdot \rho = \sum_{\alpha \in R_+} h(\alpha)^2$ as $R$ is of type ADE. Let $\text{Exp}(R)$ be the set of exponents of $R$ [Bou68, Ch. V §6 Théor. 2]. By Kostant loc. cit., we have for any map $f : \mathbb{Z}_{\geq 1} \to \mathbb{R}$ the identity $\sum_{\alpha \in R_+} f(h(\alpha)) = \sum_{m \in \text{Exp}(R)} F(m)$ with $F(m) = \sum_{u=1}^m f(u)$ (see [CL19, p. 82]). We apply this to $f(x) = x$ and $f(x) = x^2$. And using the involution $m \mapsto h - m$ of $\text{Exp}(R)$ [Bou68, Ch. V §6.2], we obtain two linear relations between $\rho \cdot \rho$ and $\sum_{m \in \text{Exp}(R)} m^2$.

Inverting the system gives the result.
Observe that for any integer \( p \geq 1 \), we have an \( A(R) \)-equivariant isomorphism
\[
P(R) \otimes \mathbb{Z}/p\mathbb{Z} \xrightarrow{\sim} \text{Hom}(Q(R), \mathbb{Z}/p\mathbb{Z})
\]
\[
\xi \mapsto (x \mapsto \xi \cdot x \mod p).
\]

Assertion (ii) and (iii) below are Propositions 3.4.1.2 and 3.2.4.8 in [CL19] (see also [Kos59]).

**Lemma 3.1.** Let \( R \) be an irreducible root system, \( h = h(R) \), and \( p \geq 1 \) an integer.

(i) Each \( W(R) \)-orbit in \( P(R)/pQ(R) \) admits a unique representative of the form \( \sum_i m_i \omega_i \) with \( m_i \geq 0 \) for all \( i \) and \( \sum_i m_i n_i \leq p \).

(ii) The kernel of any linear form \( Q(R) \rightarrow \mathbb{Z}/p\mathbb{Z} \) with \( p < h \) contains some element of \( R \).

(iii) There is a unique \( W(R) \)-orbit of linear forms \( Q(R) \rightarrow \mathbb{Z}/h\mathbb{Z} \) whose kernel does not contain any root, namely the orbit of the form \( x \mapsto \rho \cdot x \mod h \).

**Proof.** The set \( \Pi \) of \( v \in V \) with \( v \cdot \alpha_i \geq 0 \) for all \( i \), and with \( v \cdot \tilde{\alpha} \leq 1 \), is a fundamental domain for the affine Weyl group \( W_{aff}(R) = Q(R) \rtimes W(R) \) acting on \( V \) [Bou68, Chap. VI §2]. For any \( \xi \) in \( P(R) \), the \( W_{aff}(R) \)-orbit of \( \frac{1}{p}\xi \) meets thus \( \Pi \) in a unique element: this proves (i). Any linear form \( \varphi : Q(R) \rightarrow \mathbb{Z}/p\mathbb{Z} \) may be written \( \varphi(x) = \xi \cdot x \mod p \) for some \( \xi \in P(R)/pQ(R) \). Replacing \( \varphi \) by \( w(\varphi) \) for some \( w \in W(R) \) we may assume \( \xi \) has the form \( \sum_i m_i \omega_i \) with the \( m_i \) as in (i). If the kernel of \( \varphi \) contain neither the \( \alpha_i \) nor \( \tilde{\alpha} \), we must have \( m_i > 0 \) for all \( i \) and \( \sum_i m_i n_i < p \), and thus \( h - 1 = \sum_i n_i \leq \sum_i m_i n_i < p \). This proves (ii). In the case \( p = h \) this inequality implies \( m_i = 1 \) for each \( i \), hence \( \xi = \sum_i \omega_i = \rho \). For any positive root \( \alpha \) in \( R \) we have \( 0 < \alpha \cdot \rho \leq \tilde{\alpha} \cdot \rho = h - 1 \). As we have \( R = R(Q(R)) \), this shows (iii). \( \square \)

A root system \( R \) is called equi-Coxeter if its irreducible components all have the same Coxeter number, called the Coxeter number of \( R \), and denoted by \( h(R) \).

**Corollary 3.2.** Let \( R \) be an equi-Coxeter root system of rank \( l \) and Coxeter number \( h \). Then assertion (iii) of Lemma 3.1 holds and there is a unique \( W(R) \)-orbit of sublattices \( L \subset Q(R) \) with no root and \( Q(R)/L \simeq \mathbb{Z}/h\mathbb{Z} \). These lattices are of the form \( \{ x \in Q(R) \mid x \cdot \rho \equiv 0 \mod h \} \) for a Weyl vector \( \rho \) for \( R \). Assuming furthermore \( \rho \in Q(R) \), \( h \) odd and \( l(h + 1) \equiv 0 \mod 12 \), they satisfy \( \text{res } L \simeq H(\mathbb{Z}/h\mathbb{Z}) \downarrow \text{res } Q(R) \).

**Proof.** The first assertion is a trivial consequence of (iii) of Lemma 3.1 and of \( \rho \cdot \alpha = 1 \) for a simple root \( \alpha \) of \( R \). The identity \( \rho \cdot \rho = l h(h + 1)/12 \) (a consequence of (7)) shows that \( \rho \) is a nonzero isotropic vector in \( Q(R) \otimes \mathbb{Z}/h\mathbb{Z} \), so the last assertion follows from the general Lemma 3.16 below. \( \square \)
We have \( \text{res } A_n \simeq \mathbb{Z}/(n+1)\mathbb{Z} \) with \( q(\overline{1}) \equiv \frac{n}{2(n+1)} \mod \mathbb{Z} \), \( \text{res } E_6 \simeq -\text{res } A_2 \), \( \text{res } E_8 = 0 \). As \(-1\) is a square modulo 5, Corollary (3.2) implies:

**Corollary-Definition 3.3.** Let \( R \) be either \( 2A_4 \) or \( 3A_2 \), and set \( p = h(R) \) (either 5 or 3) and \( g = \text{rank } R \) (either 8 or 6). Define \( Q_p \) as the sublattice of \( Q(R) \) whose elements \( x \) satisfy \( x \cdot \rho \equiv 0 \mod p \), for a fixed Weyl vector \( \rho \) in \( Q(R) \). Then \( Q_p \) is an even lattice, without roots, satisfying \( \text{res } Q_p \simeq \text{res } E_6 \oplus H(\mathbb{Z}/p\mathbb{Z})^2 \).

**Proposition 3.4.** Assume either \( p = 5 \) and \( E \) is the root lattice \( E_8 \), or \( p = 3 \) and \( E \) is the root lattice \( E_6 \). Up to isometry, there is a unique triple of even lattices \( (A, B, C) \) with \( A \subset B \subset C \), both inclusions of index \( p \), \( C \simeq E \) and \( R(A) = \emptyset \).

**Proof.**

Set \( R = R(E) \), so that we have \( E = Q(R) \). We have to show that there is a unique \( W(R) \)-orbit of index \( p \) subgroups \( B \subset E \) such that \( B \) possesses an index \( p \) subgroup without roots, and that for such a \( B \) there is a unique \( O(B) \cap O(E) \)-orbit of index \( p \) subgroups of \( B \) without roots. We claim (provocatively) that both properties follow at once from Lemma 3.1 and an inspection of the extended Dynkin diagrams of \( E_8 \) and \( E_6 \) drawn below:

![Dynkin diagrams](image)

(Each simple root \( \alpha_i \) is labelled with the integer \( n_i \).) Indeed, assume for instance \( R \simeq E_8 \) and \( p = 5 = n_5 \). Note that the irreducible root systems with Coxeter number \( \leq 5 \) are the \( A_l \) with \( 1 \leq l \leq 4 \), so by assertion (ii) of the lemma, the irreducible components of \( R(B) \) must have this form. On the other hand, assertion (i) asserts that for a suitable choice of a positive system of \( R \) the lattice \( B \) is the kernel of \( x \mapsto \xi \cdot x \mod 5 \) with \( \xi = \sum_i m_i \varpi_i \) and \( \sum_i m_i n_i \leq 5 \). Consider the set

\[
J = \{ j \mid m_j \neq 0 \}.
\]

We must have \( |J| \leq 2 \) (note \( n_i \geq 2 \) for all \( i \)) and \( \alpha_j \in R(B) \) for \( j \notin J \). An inspection of the Dynkin diagram of \( E_8 \) shows that in the case \( |J| = 2 \), we have \( J \subset \{1, 2, 7, 8\} \) and \( \{2, 7\} \not\subset J \), and \( R(B) \) contains an irreducible root system of rank 5: a contradiction. So we have \( |J| = 1 \) and \( J \neq \{4\} \). But this clearly implies \( J = \{5\} \) and \( \xi = \varpi_5 \) by another inspection of this diagram. So \( B \) is the Borel-de Siebenthal lattice \( BS_5(R) = Q(R_5) \), and is isomorphic to the root lattice \( A_4 \oplus A_4 \). Note that we have \( h(A_4) = 5 = p \). By the last assertion of Lemma 3.1 applied to \( R_5 \), there is a unique \( W(R_5) \)-orbit of index 5 sublattices of \( Q(R_5) \) without root. As we have \( W(R_5) \subset W(R) \), this concludes the proof in the case \( R \simeq E_8 \). The case \( R \simeq E_6 \) is entirely similar. \( \square \)
Proposition 3.5. Let \((g, p, m)\) be either \((8, 5, 4)\) or \((6, 3, 5)\). Up to isometry, \(Q_g\) is the unique even lattice of rank \(g\) without roots satisfying \(Q_g^{2}/Q_g \simeq (\mathbb{Z}/p\mathbb{Z})^m\).

Moreover, \(O(Q_g)\) permutes transitively the totally isotropic planes (resp. lines, resp. flags) of \(\text{res } Q_g\). The inverse image in \(Q_g^{2}\) of such an isotropic plane (resp. line) is isometric to \(E_g\) (resp. to \(A_4 \oplus A_4\) for \(g = 8\), to \(A_2 \oplus A_2 \oplus A_2\) for \(g = 6\)).

In the statement above, by a \textit{totally isotropic flag} of \(\text{res } Q_g\) we mean a pair \((D, P)\) with \(D\) a line and \(P\) a totally isotropic plane containing \(D\).

\textbf{Proof.} Let \(A\) be an even lattice of rank \(g\) with \(A^2/A \simeq (\mathbb{Z}/p\mathbb{Z})^m\). The isomorphism class of an \(m\)-dimensional linking quadratic space \(V\) over \(\mathbb{Z}/p\mathbb{Z}\) is determined by its Gauss sum \(\gamma(V) = |V|^{-1/2} \sum_{v \in V} e^{2\pi i q(v)}\). The Milgram formula \([\text{MH73, Appendix } 4]\) asserts \(\gamma(\text{res } A) = e^{2\pi i g} = \gamma(\text{res } Q_g)\) and proves \(\text{res } A \simeq \text{res } Q_g\).

The even lattices \(L\) containing \(A\) with index \(p^i\) are in natural bijection with the totally isotropic subspaces of dimension \(i\) over \(\mathbb{Z}/p\mathbb{Z}\) inside \(\text{res } A\), via the map \(L \mapsto L/A\). We have already proved \(\text{res } A \simeq H(\mathbb{Z}/p\mathbb{Z})^2 \oplus \text{res } E_g\). By Witt’s theorem, any isotropic line (or plane) is thus part of a totally isotropic flag of \(\text{res } A\). By Proposition 3.4, it only remains to show that any even lattice \(L\) containing \(A\) with \(\dim_{\mathbb{Z}/p\mathbb{Z}} L/A = 2\) is isometric to \(E_g\). But such an \(L\) has determinant 1 in the case \(g = 8\), and determinant 3 otherwise. As is well known, this shows \(L \simeq E_8\) in the first case, and \(L \simeq E_6\) in the second (use e.g. that such a lattice must be the orthogonal of an \(A_2\) embedded in \(E_8\)). \(\square\)

This proposition implies in particular that the fixed point lattice \(Q\) considered in Lemma 2.1, in the case of an element \(c\) with shape \(1^4 5^4\), is isometric to \(Q_8\).

Proposition 3.6. For \(g = 6, 8\), the natural morphism \(O(Q_g) \rightarrow O(\text{res } Q_g)\) is an isomorphism.

\textbf{Proof.} Set \(A = Q_g\). Fix an isotropic line \(D\) in the quadratic space \(\text{res } A\) over \(\mathbb{F}_p\) (with \(p = 3\) for \(g = 6\), \(p = 5\) otherwise). We have a canonical filtration \(0 \subset D \subset D^\perp \subset \text{res } A\), and a nondegenerate quadratic space \(V = D^\perp/D\) over \(\mathbb{F}_p\). The stabilizer \(P\) of \(D\) in \(O(\text{res } A)\) is in a natural (splittable) exact sequence

\[1 \rightarrow U \rightarrow P \rightarrow \text{GL}(D) \times O(V) \rightarrow 1\]

\((P\) is a “parabolic subgroup” with “unipotent radical” \(U\)). We have an isomorphism \(\beta : U \xrightarrow{\sim} \text{Hom}(\text{res } A)/D^\perp, V)\) characterized by

\[g(x) \equiv x + \beta(g)(x) \mod D\]

for all \(g \in U\) and \(x \in \text{res } A\). (By duality \(U\) is also naturally isomorphic to \(\text{Hom}(V, D)\), but we will not need this point of view.) Denote by \(B\) the even lattice defined as the inverse image of \(D\) in \(A^2\). We have natural isomorphisms \(V \simeq \text{res } B\) and \(B/A \simeq D\) (see Lemma 3.16 (i)). The stabilizer \(S\) of \(D\) in \(O(A)\) is \(O(A) \cap O(B)\). By Proposition 3.5, we are left to check that the natural map
$S \to P$ is an isomorphism. We first study $O(A) \cap O(B)$. Set $k = g/(p - 1)$. By the same proposition, we may also assume that we have

$$B = A^k_{p-1} \quad \text{and} \quad A = \{(a_i)_{1 \leq i \leq k} \in B \mid \sum_{i=1}^{k} \rho' \cdot a_i \equiv 0 \mod p\},$$

where $\rho'$ is some Weyl vector in $A_{p-1}$ (e.g. the vector $((p - 1)/2, ..., -(p - 1)/2)$).

Let $R = kA_{p-1}$ be the root system of $B$. For general reasons, the subgroup $G(R)$ of $A(R)$ fixing the Weyl vector $\rho = (\rho', \ldots, \rho')$ of $R$ is naturally isomorphic to $\{\pm 1\}^k \rtimes \mathfrak{S}_k$ (automorphisms of the Dynkin diagram of $R$), and we have $O(B) = A(R) = W(R) \rtimes G(R)$. This proves

$$O(B) \simeq \mathfrak{S}_k^k \rtimes (\{\pm 1\}^k \rtimes \mathfrak{S}_k).$$

We trivially have $G(R) \subset O(A)$, hence we only have to determine $W(R) \cap O(A)$. By definition of $A$, this is the subgroup of $W(R)$ preserving $\mathbb{Z}_p + pP(R)$. As $\rho$ is in $Q(R)$ and $pP(R) \subset Q(R)$, $W(R) \cap O(A)$ is also the subgroup of $W(R)$ preserving the subspace of the quadratic space $Q(R) \otimes \mathbb{F}_p$ generated by $\rho$ and its kernel $pP(R)/pQ(R)$. But the kernel of $A_{p-1} \otimes \mathbb{F}_p$ is generated by the image $e$ of the vector $(1 - p, 1, \ldots, 1)$, and is fixed by $\mathfrak{S}_p$. So $W(R) \cap O(A)$ is the subgroup of $(\sigma_1, \ldots, \sigma_k)$ in $\mathfrak{S}_p^k$ such that there is $\lambda$ in $\mathbb{F}_p^*$ such that for all $j = 1, \ldots, k$ there is $b_j$ in $\mathbb{F}_p$ with

$$(9) \quad \sigma_j(\rho') \equiv \lambda \cdot \rho' + b_j \mod pA_{p-1}. $$

To go further it will be convenient to identify $A_{p-1}$ with the subgroup of $(x_i)_{i \in \mathbb{F}_p}$ in $\mathbb{Z}_p^k$ satisfying $\sum_i x_i = 0$ in such a way that we have $\rho'_i = i$ for all $i$ in $\mathbb{F}_p$. If we do so, $W(R) \cap O(A)$ becomes the subgroup of $(\sigma_1, \ldots, \sigma_k)$ in $\mathfrak{S}_p^k$ such that there is $\lambda$ in $\mathbb{F}_p^*$ and $b_1, \ldots, b_k$ in $\mathbb{F}_p$ with $\sigma_j^{-1}(i) = \lambda i + b_j$ for all $i$ in $\mathbb{F}_p$ and all $j = 1, \ldots, k$ ("$k$ affine transformations with common slope"). We have shown

$$W(R) \cap O(A) = \mathbb{F}_p^k \rtimes \mathbb{F}_p^*$$

and

$$(10) \quad O(A) \cap O(B) = \mathbb{F}_p^k \rtimes (\mathbb{F}_p^x \rtimes (\{\pm 1\}^k \rtimes \mathfrak{S}_k)).$$

It remains to identify the action of this group on res $A$. The reduction modulo $A$ of the natural inclusions $A \subset B \subset B^2 \subset A^2$, is $0 \subset D \subset D^\perp \subset \text{res } A$ by definition, and we have set $V = \text{res } B$. Note that res $A$ is generated by $D^\perp$ and the image of the vector $p^{-1} \rho$, and that $W(R)$ acts trivially on $V$. Dividing Formula (9) by $p$ gives the action of $W(R) \cap O(A)$ on (res $A$)/$D$:

- $\lambda$ is an element of $\text{GL}((\text{res } A)/D^\perp)$, which is naturally isomorphic to $\text{GL}(D)$ by duality, and
- for $\lambda = 1$, i.e. when considering an element of $W(R) \cap O(A)$ mapping to $U$, the family $(b_j)_{1 \leq j \leq k}$ is the matrix of an element of $\text{Hom}((\text{res } A)/D^\perp, V)$ in the bases $p^{-1} \rho$ of $(\text{res } A)/D^\perp$ and $((p^{-1} e, 0, \ldots, 0), \ldots, (0, \ldots, 0, p^{-1} e))$ of $V$. 
The natural map $O(A) \to O(\text{res } A)$ thus identifies $W(R) \cap O(A)$ with the inverse image of $GL(D) \times 1$ in $P$. In order to conclude that $O(A) \cap O(B) \to P$ is an isomorphism, we are left to check that the natural map
\[
\{\pm 1\}^k \times \mathfrak{S}_k \to O(\text{res } A^k_{p-1}) = O(I_k \otimes \mathbb{F}_p)
\]
is an isomorphism. Injectivity is clear (for any $p > 2$ and $k > 0$). Surjectivity is particular to the two cases at hand: for $(p, k) = (3, 3)$ or $(5, 2)$, the only elements of norm 1 in $I_k \otimes \mathbb{F}_p$ are the standard basis elements and their opposites. \qed

**Proposition 3.7.** The lattice $Q_8$ is orientable, whereas $Q_6$ is not.

**Proof.** Set again $A = Q_g$ and $p = 3$ (case $g = 6$) or $p = 5$ (case $g = 8$). We will view the linking quadratic space $\text{res } A$ over $\mathbb{Z}/p\mathbb{Z}$ as traditional quadratic space over $\mathbb{Z}/p\mathbb{Z}$ by multiplying its quadratic form by $p$ (making it $\mathbb{Z}/p\mathbb{Z}$-valued instead of $\frac{1}{p}\mathbb{Z}/\mathbb{Z}$-valued). This quadratic space is nondegenerate and isotropic (it has dimension > 2) so by a classical theorem of Eichler [Die71, Ch. II §8.I] the determinant and spinor norm maps induce an isomorphism
\[
O(\text{res } A)^{ab} \simeq \{\pm 1\} \times (\mathbb{F}_p^\times \otimes \mathbb{Z}/2\mathbb{Z}).
\]
We will give two elements $\gamma, \gamma'$ of $O(A)$ inducing orthogonal reflections of $\text{res } A$ and with distinct spinor norms. The previous proposition and (11) will then imply that $\gamma$ and $\gamma'$ generate $O(A)^{ab}$.

Set $k = g/(p - 1)$. By definition, $A$ is the index $p$ subgroup of the root lattice $B = A^k_{p-1}$ defined by $x \cdot \rho \equiv 0 \mod p$, where $\rho = (\rho', \ldots, \rho')$ is a fixed Weyl vector in $B$. As already seen in the proof of Proposition 3.6 the subgroup $G$ of $O(B)$ fixing $\rho$ is a subgroup of $O(A)$ naturally isomorphic to $\{\pm 1\}^k \times \mathfrak{S}_k$. The subgroup $1 \times \mathfrak{S}_k \subset G$ is the obvious one, but the element $(-1, 1, \ldots, 1) \times 1$ acts on $B$ as $(x_1, \ldots, x_k) \mapsto (-\sigma x_1, x_2, \ldots, x_k)$, where $\sigma$ in $\mathfrak{S}_p$ is the unique element sending $\rho'$ to $-\rho'$. We take $\gamma, \gamma'$ in $G$ with $\gamma = (-1, 1, \ldots, 1) \times \text{id}$ and $\gamma' = (1, \ldots, 1) \times \tau$, where $\tau$ is a transposition in $\mathfrak{S}_k$. Then $\gamma$ and $\gamma'$ act trivially on $A^2/B^2 = \langle p^{-1}\rho \rangle$ and induce orthogonal reflections of $\text{res } B$ and $\text{res } A$, with spinor norm $\frac{1}{2} \det(\text{res } A^2_{p-1})$ for $\gamma$ and $2 \cdot \frac{1}{2} \det(\text{res } A^2_{p-1})$ for $\gamma'$. We actually have $\frac{1}{2} \det(\text{res } A^2_{p-1}) \equiv \frac{p-1}{2}$ in $(\mathbb{Z}/p\mathbb{Z})^\times$, but what only matters for this proof is that these spinor norms are distinct, as 2 is not a square in $(\mathbb{Z}/p\mathbb{Z})^\times$ for $p = 3, 5$.

We have $\det \gamma |_A = (-1)^{(p-1)/2}$ and $\det \gamma' |_A = (-1)^{p-1} = 1$: this shows that det is trivial on $O(A)$ for $p = 5$ but not for $p = 3$. \qed

For $g = 6, 8$, we have seen that there is a unique $O(Q_g)$-orbit of overlattices $E \supset Q_g$ isomorphic to $E_g$. We now define $Q_{2g}$ by a doubling process.

**Definition 3.8.** Set $(g, p) = (6, 3)$ or $(8, 5)$ and fix an embedding $Q_g \subset E_g$ arbitrarily. Define $Q_{2g}$ as the sublattice of $E_g \oplus E_g$ consisting of elements $(x, y)$.
satisfying $x + y \in Q_g$. Then $Q_{2g}$ is an even lattice, without roots, satisfying $\text{res } Q_{2g} \simeq H(\mathbb{Z}/p\mathbb{Z})^2 \oplus \text{res } E_g^2$.

Let us check the last assertion in the definition above. Note that a root in $E_g \oplus E_g$ must belong either to $E_g \oplus 0$ or to $0 \oplus E_g$, so the fact that $Q_g$ has no root implies that $Q_{2g}$ has no root either. The assertion on the residue of $Q_{2g}$ follows from $(E_g \oplus E_g)/Q_{2g} \simeq (\mathbb{Z}/p\mathbb{Z})^2$, the fact that $\text{res } Q_{2g}$ is a subquotient of the $\mathbb{Z}/p\mathbb{Z}$-vector space $\text{res } Q_g \oplus \text{res } Q_g$, and Lemma 3.16. The following statements are analogues of Propositions 3.4 and 3.5 (although their proofs are slightly different).

**Proposition 3.9.** Set $(g, p) = (6, 3)$ or $(8, 5)$ and $E = E_g$. Up to the action of $O(E) \times O(E)$ there is a unique sublattice $A$ of index $p^2$ in $E \oplus E$ without roots. For such an $A$, the natural map $O(A) \cap (O(E) \times O(E)) \rightarrow \text{GL}((E \oplus E)/A)$ is surjective.

**Proof.** Fix $A$ as in the statement. The sublattice $A \cap (E \oplus 0)$ of $E \oplus 0$ has index dividing $p^2$ and has no root, so by Proposition 3.4 it has index $p^2$ and there is $\gamma$ in $O(E)$ with $(\gamma \times 1)(A \cap (E \oplus 0)) = Q_g \oplus 0$. Arguing similarly with $A \cap (0 \oplus E)$, we obtain the existence of $h$ in $O(E) \times O(E)$ such that $h(A)$ contains $Q_g \oplus Q_g$. Set $A' = h(A)$.

Denote by $P$ the totally isotropic plane $E/Q_g$ of $\text{res } Q_g$, and by $I$ the plane $A'/(Q_g \oplus Q_g)$ inside $P \oplus P$. We have seen that the two natural projections $I \rightarrow P$ are injective, hence bijective. There is thus an element $\varphi$ in $\text{GL}(P)$ with $I = \{ (x, \varphi(x)), x \in P \}$. Set $S = O(E) \cap O(Q_g)$. By Proposition 3.6, the natural morphism $S \rightarrow \text{GL}(P)$ is surjective. By multiplying $h$ by a suitable element in $1 \times O(E)$ we may thus assume that we have $\varphi = -\text{id}_P$, that is, $A' = Q_{2g}$. We have proved the first assertion. For the second, observe that $S$ embeds diagonally in $O(E) \times O(E)$, and as such, it preserves $Q_{2g}$ and acts on the totally isotropic plane $P' = (E \oplus E)/Q_{2g}$ of $\text{res } Q_{2g}$. Moreover, the natural map $E/Q_g \rightarrow (E \oplus E)/Q_{2g}$, $x \mapsto (x, 0) \mod Q_{2g}$, defines an $S$-equivariant isomorphism $P \rightarrow P'$. The surjectivity of $S \rightarrow \text{GL}(P)$ thus implies that of $S \rightarrow \text{GL}(P')$. \hfill $\Box$

**Proposition 3.10.** Let $(g, p, m)$ be either $(8, 5, 4)$ or $(6, 3, 6)$. Up to isometry, $Q_{2g}$ is the unique even lattice of rank $2g$ without roots satisfying $Q_{2g}^p/Q_{2g} \simeq (\mathbb{Z}/p\mathbb{Z})^m$.

Moreover, $O(Q_{2g})$ permutes transitively the totally isotropic planes (resp. lines, resp. flags) of $\text{res } Q_{2g}$. The inverse image in $Q_{2g}^p$ of such an isotropic plane (resp. line) is isometric to $E_g \oplus E_g$ (resp. to an even lattice with root system $m\mathbf{A}_{p-1}$).

**Proof.** Let $A$ be an even lattice of rank $2g$ with $A^2/A \simeq (\mathbb{Z}/p\mathbb{Z})^m$. The Milgram formula applied to $A$ and $Q_{2g}$ shows $\text{res } A \simeq \text{res } Q_{2g}$ (see the proof of Corollary 3.5). The even lattices $L$ containing $A$ with index $p^2$ are in natural bijection with
the totally isotropic subspaces of dimension $i$ over $\mathbb{Z}/p\mathbb{Z}$ inside $\text{res } A$, via the map $L \mapsto L/A$. As we have $\text{res } A \simeq H(\mathbb{Z}/p\mathbb{Z})^2 \oplus \text{res } E_2^2$, the maximal isotropic subspaces of $\text{res } A$ have dimension 2 over $\mathbb{Z}/p\mathbb{Z}$. Fix such a plane in $\text{res } A$ and denote by $F$ its inverse image in $A^i$. We have $\text{res } F \simeq \text{res } E_2^2$, so $F$ is an even lattice with same rank and residue as $E_2 \oplus E_2$.

Assume first $g = 8$. Then $F$ is unimodular. We know since Witt that it is either isometric to $E_8 \oplus E_8$, or to a certain lattice $E_{16}$ with root system $D_{16}$. Assuming furthermore that $A$ has no root, we claim that the $F$ cannot be isometric to $E_{16}$. Indeed, using the method explained in the proof of Proposition 3.4, Lemma 3.1 (i) and an inspection of the Dynkin diagram of $D_{16}$ (including the $n_i$'s):

```
1 2 2 2 2 2 2 2 2 2
1```

show that an index 5 subgroup of $D_{16}$ always contains an irreducible root system isomorphic to $A_5$. But $A_5$ has Coxeter number 6, so $A_5$ has no index 5 subgroup without roots by Lemma 3.1 (ii): this proves the claim.

Assume now $g = 6$. We have $\text{res } F \simeq -\text{res } A_3^2$. This is well-known to imply that $F$ is isometric to $E_6 \oplus E_6$, $E_8 \oplus A_2 \oplus A_2$ or to a certain lattice $E_{12}$ having root system $D_{10}$. (One way to prove this is to start by observing that such a lattice is the orthogonal of some $A_2 \oplus A_2$ embedded an even unimodular lattice, hence in $E_8 \oplus E_8$ or in $E_{16}$. ) An inspection of the Dynkin diagrams of $E_8$ and $D_{10}$ shows that an index 3 subgroup of $E_9$ or $D_{12}$ always contains an irreducible root system isomorphic to $A_3$, whose Coxeter number is $> 3$. Assuming $A$ has no root, this implies $F \simeq E_6 \oplus E_6$ by Lemma 3.1 (ii).

We have just shown that in both cases, assuming $A$ has no roots, the inverse image in $A^i$ of a totally isotropic plane of $\text{res } A$ is isometric to $E_6 \oplus E_6$. By Proposition 3.4, there is a unique isometry class of pairs $(A, F)$ with $F \simeq E_6 \oplus E_6$, $A$ of index $p^2$ in $F$, and $R(A) = \emptyset$. This shows $A \simeq Q_{2g}$ as well as the transitivity of $O(Q_{2g})$ on the totally isotropic planes in $\text{res } Q_{2g}$. Moreover, the same proposition also asserts that the stabilizer in $O(Q_{2g})$ of an isotropic plane $P$ in $\text{res } Q_{2g}$ surjects naturally onto $\text{GL}(P)$. This shows the transitivity of $O(Q_{2g})$ on the isotropic lines (resp. flags) in $\text{res } Q_{2g}$.

Fix an even lattice $B \subset E_6$ containing $Q_6$ with index $p$. We known from Proposition 3.4 that such a $B$ exists and is a root lattice with root system $\frac{g}{p-1} A_{p-1}$. The sublattice $C \subset E_6 \oplus E_6$ whose elements $(x, y)$ satisfy $x + y \in B$ contains $Q_{2g}$, and defines an isotropic line $C/Q_{2g}$ in $\text{res } Q_{2g}$. Its root system $R(C)$ is isomorphic to $2 \frac{g}{p-1} A_{p-1}$. This concludes the proof of the proposition.

**Proposition 3.11.** For $g = 6, 8$, the natural morphism $O(Q_{2g}) \to O(\text{res } Q_{2g})$ is surjective, with kernel isomorphic to $\mathbb{Z}/3\mathbb{Z}$ for $g = 6$, $\mathbb{Z}/5\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$ for $g = 8$. 

Proof. Set $E = E_q$, $Q = Q_q$ and consider the group $S = O(E) \cap O(Q)$. The inclusions $Q \subset E \subset E^2 \subset Q^2$ define a composition series $U_1 \lhd U_2 \lhd U_3 \lhd S$, where:

- $U_3$ is the kernel of the natural morphism $\beta : S \to \text{GL}(E/Q)$,
- $U_2$ is the kernel of the natural morphism $\beta_3 : U_3 \to O(\text{res } E)$,
- $U_1$ is the kernel of the natural morphism $\beta_2 : U_2 \to \text{Hom}(E^3/E, E/Q)$ given by $g(x) = x + \beta_2(g)(\overline{x})$ for all $g$ in $U_2$ and all $x$ in $E^2$ with image $\overline{x}$ in $E^2/E$.

Moreover, if $\text{Hom}(Q^2/E^2, E/Q)^{\text{antisym}}$ denotes the group of antisymmetric group homomorphisms $Q^2/E^2 \to E/Q$, with $E/Q$ identified with $\text{Hom}(Q^2/E^2, Q/\mathbb{Z})$ using the symmetric bilinear form of $Q \otimes \mathbb{Q}$, we have a natural morphism:

- $\beta_1 : U_1 \to \text{Hom}(Q^2/E^2, E/Q)$, given by $g(x) = x + \beta_1(g)(\overline{x})$ for all $g$ in $U_1$ and all $x$ in $Q^2/E^2$ with image $\overline{x}$ in $Q^2/E^2$.

Last but not least, since the natural map $O(Q) \to O(\text{res } Q)$ is an isomorphism by Proposition 3.6, the morphisms $\beta$, $\beta_3$, $\beta_2$ above are surjective, and $\beta_1$ is an isomorphism. Let $p$ denote the prime such that we have $E/Q \simeq (\mathbb{Z}/p\mathbb{Z})^2$, we have proved in particular $U_1 \simeq \mathbb{Z}/p\mathbb{Z}$.

Set now $F = E \oplus E$, $A = Q_{2q}$ and consider the group $T = O(F) \cap O(A)$. On the one hand, we have $O(F) = O(E)^2 \rtimes \mathfrak{S}_2$. As $\mathfrak{S}_2$ clearly stabilizes $A$, this shows

$$T = G \rtimes \mathfrak{S}_2 \quad \text{with} \quad G = \{(g_1, g_2) \in S \times S \mid \beta(g_1) = \beta(g_2)\}.$$ 

On the other hand, $T$ is also the stabilizer in $O(A)$ of the subspace $F/A$ of res $A$. By Proposition 3.10 we are left to prove that the natural morphism $\nu : T \to \overline{T}$, where $\overline{T}$ is the stabilizer of $F/A$ in $O(\text{res } A)$, is a surjection whose kernel is as in the statement.

To the inclusions $A \subset F \subset F^2 \subset A^2$ is associated as above a composition series $V_1 \lhd V_2 \lhd V_3 \lhd \overline{T}$, whose successive quotients $\overline{T}/V_3$, $V_3/V_2$, $V_2/V_1$ and $V_1$ are naturally identified with the groups $\text{GL}(F/A)$, $O(\text{res } F)$, $\text{Hom}(F^2/F, F/A)$ and $\text{Hom}(A^2/F^2, F/A)^{\text{antisym}}$. The following observations below will prove $\nu(U_i \times U_i \times \mathfrak{S}_2) = V_i$ for $i = 1, 2, 3$, $\nu(T) = \overline{T}$ and identify ker $\nu$.

**Action of $\mathfrak{S}_2$.** By definition of $A$ the group $\mathfrak{S}_2$ acts trivially on $F/A$, hence on $A^2/F^2$ as well. Moreover, it swaps the two factors of res $F = \text{res } E \oplus \text{res } E$. Recall that this linking quadratic space is 0 for $g = 8$, isomorphic to $H(\mathbb{Z}/3\mathbb{Z})$ for $g = 6$. As $V_2$ is a $p$-group and $p$ is odd it follows that $\mathfrak{S}_2$ acts trivially on res $A$ for $g = 8$.

**Action of $G$ on $F/A$.** As $\mathfrak{S}_2$ acts trivially on $F/A$, Proposition 3.9 implies that $\nu$ induces an isomorphism $T / (U_3 \times U_3) \times \mathfrak{S}_2 \simeq \overline{T}/V_3$.

**Restriction of $\nu$ to $(U_3 \times U_3) \times \mathfrak{S}_2$.** For $g = (g_1, g_2)$ in $U_3 \times U_3$ and $(x_1, x_2)$ in $F^2 = E^3 \oplus E^3$, we have $g(x_1, x_2) \equiv (g_1(x_1), g_2(x_2)) \mod F$. So $\nu$ induces an isomorphism between $U_3/U_2 \times U_3/U_2$ and the subgroup $O(\text{res } E) \times O(\text{res } E)$ of $O(\text{res } E \oplus \text{res } E)$. This subgroup has index 2 for $g = 6$ (and 1 for $g = 8$) but recall that in this case $\mathfrak{S}_2$ swaps the two factors of res $E \oplus \text{res } E$.
Restriction of $\nu$ to $U_2 \times U_2$. The map $\iota : E/Q \to F/A, x \mapsto (x,0)$, is an isomorphism. For $g = (g_1, g_2)$ in $U_2 \times U_2$ and $(x_1, x_2)$ in $F^{\mathbb{Z}} = E^{\mathbb{Z}} \oplus E^{\mathbb{Z}}$ we thus have the following equalities in $F/A$:

$$g(x_1, x_2) - (x_1, x_2) = (\beta_2(g_1)(x_1), \beta_2(g_2)(x_2)) = \iota(\beta_2(g_1)(x_1) + \beta_2(g_2)(x_2)).$$

This shows that $\nu$ induces an isomorphism $U_2/U_1 \times U_2/U_1 \sim V_2/V_1$.

Restriction of $\nu$ to $U_1 \times U_1$. We have $A^2 = \{(y_1, y_2) \in Q^2 \oplus Q^2 \mid y_1 \equiv y_2 \mod E^2\}$. For $g = (g_1, g_2)$ in $U_1 \times U_1$ and $(x_1 + y, x_2 + y)$ in $A^2$ with $x_i$ in $E^{\mathbb{Z}}$ and $y$ in $Q^2$, we have the following equality in $F/A$ (with $\iota$ defined as above):

$$g(x_1 + y, x_2 + y) - (x_1 + y, x_2 + y) = (\beta_1(g_1)(y), \beta_1(g_2)(y)) = \iota(\beta_1(g_1)(y) + \beta_1(g_2)(y)).$$

This shows $\nu(U_1 \times U_1) = V_1$ and

$$(12) \quad \ker \nu_{U_1 \times U_1} = \{(g_1, g_2) \in U_1 \times U_1 \mid \beta_1(g_1) + \beta_1(g_2) = 0\} \cong \mathbb{Z}/p\mathbb{Z}.$$ 

All in all, we have shown $\nu(T) = T$, and if $K \cong \mathbb{Z}/p\mathbb{Z}$ denotes the group in (12), $\ker \nu = K \times \mathfrak{S}_2$ for $g = 8$, and $\ker \nu = K$ for $g = 6$. \hfill \square

Proposition 3.12. The lattice $Q_{12}$ is orientable.

Proof. As the kernel of $O(Q_{12}) \to O(\text{res } Q_{12})$ has odd cardinality (namely 3) by Proposition 3.11, it is contained in $SO(Q_{12})$. Arguing as in the proof of Proposition 3.7, we are left to find two elements $g, g'$ in $O(Q_{12})$ with determinant 1 and whose images in $O(\text{res } Q_{12})$ are reflections with distinct spinor norms. In the following arguments, it will be convenient to view linking quadratic spaces over $\mathbb{Z}/3\mathbb{Z}$ as traditional quadratic spaces over $\mathbb{Z}/3\mathbb{Z}$ by multiplying their quadratic form by 3 (which becomes then $\mathbb{Z}/3\mathbb{Z}$-valued instead of $\frac{1}{3}\mathbb{Z}/\mathbb{Z}$-valued), so that it makes sense to talk about their determinant.

Consider first the non-trivial element $g$ of the group $\mathfrak{S}_2$ naturally acting on $E_6 \oplus E_6$. Then $g$ acts trivially on $(E_6 \oplus E_6)/Q_{12}$, and in the obvious way on res $E_6 \oplus \text{res } E_6$. It acts thus as a reflection with spinor norm $2 \cdot \frac{1}{2} \det(\text{res } E_6)$ in $(\mathbb{Z}/3\mathbb{Z})^\times$ (the squares of $(\mathbb{Z}/3\mathbb{Z})^\times$ are $\{1\}$). Moreover, we have $\det g = (-1)^6 = 1$.

Let $s$ be an order two element of $O(Q_6) \cap O(E_6)$ acting trivially on $E_6/Q_6$ and by $-1$ on $\text{res } E_6$. Such an $s$ exists by Proposition 3.6. By construction, it is a reflection in $O(\text{res } Q_6)$ with spinor norm $\frac{1}{2} \det(\text{res } E_6) = \det(\text{res } A_2)$ in $(\mathbb{Z}/3\mathbb{Z})^\times$. So $s$ is conjugate in $O(Q_6)$ to the element denoted $\gamma'$ in the proof of Proposition 3.7, and we have thus $\det s = \det \gamma' = 1$ as was shown loc. cit. Consider now the order 2 element $g' = (s, 1)$ in $O(E_6) \times O(E_6)$. As $s$ preserves $Q_6$ and acts trivially on $E_6/Q_6$, the element $g'$ preserves $Q_{12}$ and has a trivial image in $\text{GL}(E_6 \oplus E_6)/Q_{12})$. It acts as $\text{diag}(-1, 1)$ in res $E_6 \oplus \text{res } E_6$. It acts thus on res $Q_{12}$ as a reflection with spinor norm $\frac{1}{2} \det(\text{res } E_6)$. This spinor norm is not the same as that of $g$ as 2 is not a square in $(\mathbb{Z}/3\mathbb{Z})^\times$. The orientability of $Q_{12}$ follows then from the equalities $\det g' = \det s \times 1 = 1$. \hfill \square
We finally set $Q_0 = 0$ and $Q_{24} = \text{Leech}$. We denote by $n_g$ the number of isometric embeddings $Q_g \to \text{Leech}$, and by $K_g$ the kernel of the morphism $O(Q_g) \to O(\text{res } Q_g)$. By Propositions 3.6 and 3.11 we have $|K_g| = 1$ for $g < 12$, $|K_{12}| = 3$, $|K_{16}| = 10$, and of course $K_{24} = O(\text{Leech})$.

**Proposition 3.13.** For $g$ in $\{0, 8, 12, 16, 24\}$ there is a unique $O(\text{Leech})$-orbit of sublattices $Q$ of Leech with $Q \simeq Q_g$, and we have $n_g |K_{24-g}| = |O(\text{Leech})|.$

**Proof.** Let $Q$ be a sublattice of Leech isomorphic to $Q_g$. By [CL19, Prop. B.2.2 (d)], the lattice $Q^\perp$ satisfies $\text{res } Q^\perp \simeq -\text{res } Q$. By Propositions 3.5 and 3.10, we have $Q^\perp \simeq Q_{g'}$ with $g' = 24-g$. Moreover, the stabilizer of $Q$ in $O(\text{Leech})$ trivially coincides with that of $Q^\perp$. To prove uniqueness we are thus left to show that there is a unique $O(Q_g) \times O(Q_{g'})$-orbit of overlattices $L \supset Q_g \oplus Q_{g'}$ with $L \simeq \text{Leech}$. Note that the existence of such an $L$ follows from Lemma 2.1.

Consider now an arbitrary maximal isotropic subspace $I$ in $\text{res } Q_g \oplus \text{res } Q_{g'}$ (which is a hyperbolic linking quadratic space over $\mathbb{F}_p$ with $p = 5$ or $3$). Let $L$ be the inverse image of $I$ in $Q_g^\perp \oplus Q_{g'}^\perp$, an even unimodular lattice. We assume furthermore that it has no root. Then $L \cap (Q_g^\perp \oplus 0)$ is an even lattice without root containing $Q_g \oplus 0$. By Propositions 3.5 and 3.10 it must be $Q_g \oplus 0$, and similarly we have $L \cap (0 \oplus Q_{g'}^\perp) = 0 \oplus Q_{g'}$. It follows that both projections $I \to \text{res } Q_g$ and $I \to \text{res } Q_{g'}$ are injective, hence isomorphisms. So there is an isometry $\varphi : \text{res } Q_g \simeq -\text{res } Q_{g'}$, such that we have $I = I_\varphi$, with $I_\varphi = \{(x, \varphi(x)), x \in \text{res } Q_g\}$. By Propositions 3.6 and 3.11, the map $O(Q_{g'}) \to O(\text{res } Q_{g'})$ is surjective. This shows that $1 \times O(Q_{g'})$ permutes transitively the $I_\varphi$, and that the stabilizer in this group of any $I_\varphi$ is the kernel of $O(Q_{g'}) \to O(\text{res } Q_{g'})$, and we are done. \hfill $\Box$

We have also proved above the following:

**Corollary 3.14.** Fix $g$ in $\{0, 8, 12, 16, 24\}$ and an isometric embedding of $Q_g \oplus Q_{g'}$ in Leech, with $g' = 24-g$. The stabilizer $S$ of $Q_g$ in $O(\text{Leech})$ is $O(\text{Leech}) \cap (O(Q_g) \times O(Q_{g'}))$ and the natural map $S \to O(Q_g)$ is surjective with kernel $1 \times K_{g'}$.

**Proposition 3.15.** The lattice $Q_{16}$ is orientable.

**Proof.** Fix an isometric embedding of $Q_8 \oplus Q_{16}$ in Leech. By Corollary 3.14, for any $\gamma$ in $O(Q_{16})$ there is $\gamma'$ in $O(Q_8)$ such that $\gamma \oplus \gamma'$ is in $O(\text{Leech})$. As any element of $O(\text{Leech})$ has determinant $1$ we have $\det \gamma \det \gamma' = 1$. But we have $\det \gamma' = 1$ as $Q_8$ is orientable, hence $\det \gamma = 1$. \hfill $\Box$

We have used several times the following simple lemma.

**Lemma 3.16.** Let $L$ be an even lattice.

(i) The map $M \mapsto M/L$ defines a bijection between the set of even lattices $M$ in $L \otimes \mathbb{Q}$ containing $L$ and the set of totally isotropic subgroups $I \subset \text{res } L$ (that is, with $q(I) = 0$). In this bijection, we have $\text{res } M \simeq I^\perp/I$. If
furthermore $I$ is a direct summand of the abelian group $\text{res } L$, and if $|I|$ is odd, then we have a noncanonical isomorphism $\text{res } L \simeq H(I) \oplus \text{res } M$.

(ii) Let $h$ be an odd integer $\geq 1$ and $x \in L$ with $x \cdot x \equiv 0 \mod h$. Assume that the natural map $L \to \mathbb{Z}/h\mathbb{Z}, y \mapsto y \cdot x \mod h$ is surjective, and denote by $M$ its kernel. Then $M$ is an even lattice with $L/M \simeq \mathbb{Z}/h\mathbb{Z}$ and res $M \simeq \text{res } L \oplus H(\mathbb{Z}/h\mathbb{Z})$.

Proof. The first two assertions in (i) are obvious [CL19, Prop. 2.1.1]. For the last assertion of (i) choose first a subgroup $J$ of $I^\perp$ with $I^\perp = J \oplus I$. Then $J$ is nondegenerate in $\text{res } L$, $I$ is a totally isotropic direct summand of $V := J^\perp$, and we have an exact sequence $0 \to I \to V \to \text{Hom}(I, Q/\mathbb{Z}) \to 0$. We now argue as in the proof of Proposition 2.1.2 of [CL19] (beware however that the statement loc. cit. does not hold for linking quadratic spaces of even cardinality). Choose a supplement $I'$ of $I$ in $V$, i.e. $V = I \oplus I'$. As $V$ is nondegenerate, any bilinear form on $I'$ is of the form $(x, y) \mapsto x \cdot \varphi(y)$ for some morphism $\varphi : I' \to I$. We apply this to the form $(x, y) \mapsto \frac{1}{2} x \cdot y$, which is well defined as $|V|$ is odd. Then the subgroup $\{x - \varphi(x), x \in I'\}$ is a totally isotropic supplement of $I$ in $V$. This implies $V \simeq H(I)$ (see Proposition-Definition 2.1.3 loc. cit.).

For assertion (ii), consider the natural map $M^s \to \mathbb{Z}/h\mathbb{Z}, y \mapsto y \cdot x \mod h$. This is well defined as we have $x \in M$ by assumption, and its restriction to $L$ induces an isomorphism $L/M \overset{\sim}{\to} \mathbb{Z}/h\mathbb{Z}$. So $L/M$ is a direct summand of $\text{res } M$ and we conclude the proof by (i).

4. Standard $L$-functions of the eigenforms $F_g$

In this section, we show that the Siegel modular forms $F_g$ defined in (2) are eigenforms and give an expression for their standard $L$-functions.

Proposition 4.1. Let $L$ be an integral lattice whose roots generate $L \otimes \mathbb{R}$. For any $g \geq 1$, there is no nonzero, $O(L)$-invariant, alternating $g$-form on $L$.

Proof. Let $\omega : L^g \to \mathbb{R}$ be such a form. It is enough to show $\omega(x_1, \ldots, x_g) = 0$ for any $x_1, \ldots, x_g$ in $L$, with $x_i$ roots of $L$. Fix such $x_i$ and let $s$ be the reflection associated to the root $x_i$. We have $s \in O(L)$ as $L$ is integral, $s(x_i) = -x_i$ and $s(x_i) \in x_i + \mathbb{Z}x_i$ for all $i$, hence the following equalities

$$\omega(x_1, x_2, \ldots, x_g) = \omega(s(x_1), s(x_2), \ldots, s(x_g)) = -\omega(x_1, x_2, \ldots, x_g) = 0.$$

Fix an integer $n \equiv 0 \mod 8$ and consider the set $\mathcal{L}_n$ of even unimodular lattices in the standard Euclidean space $V = \mathbb{R}^n$. For all $g \geq 1$ we denote by $\text{Alt}_n^g$ the free $\mathbb{R}$-vector space with generators the $(L, \omega)$, with $L$ in $\mathcal{L}_n$ and $\omega$ an alternating $g$-form on $V$, and with relations the

$$(\gamma^{-1}(L), \omega \circ \gamma) = (L, \omega) \quad \text{and} \quad (L, \lambda \omega + \omega') = \lambda (L, \omega) + (L, \omega'),$$
for all $L$ in $L_n$, all $\gamma$ in $O(V)$, all alternating $g$-forms $\omega, \omega'$ on $V$ and all $\lambda$ in $\mathbb{R}$. It follows readily from these definitions that the Siegel theta series construction $(L; \omega) \mapsto \Theta(L; \omega) = \sum_{\gamma \in L_n} \omega(\gamma) q^{\frac{1}{2} \lambda^2}$ factors through an $\mathbb{R}$-linear map

\begin{equation}
\Theta : \text{Alt}_g \longrightarrow S_{n/2+1}(\text{Sp}_2(\mathbb{Z})).
\end{equation}

If $L_1, \ldots, L_h$ denote representatives for the isometry classes of even unimodular lattices in $V$, we also have an $\mathbb{R}$-linear isomorphism

\begin{equation}
\text{Alt}_g \cong \bigoplus_{i=1}^h (A^g V^*)^O(L_i).
\end{equation}

The classification of even unimodular lattices in rank $\leq 24$ (or simply, Venkov’s argument in [CS99, Chap. 18, §2, Prop. 1]) shows that apart from Leech these lattices are generated over $\mathbb{Q}$ by their roots. Proposition 4.1 and Formula (14) thus show that $\text{Alt}_g$ vanishes for $n < 24$, and together with (1), imply:

**Proposition 4.2.** $\text{Alt}_g$ has dimension 1 for $g$ in \{8, 12, 16, 24\}, 0 otherwise.

Let us denote by $O_n$ the orthogonal group scheme of a fixed even unimodular lattice of rank $n$, e.g. of $D_n + \mathbb{Z} e$ with $e = \frac{1}{2}(1, \ldots, 1)$. For any finite dimensional representation $U$ of $O(V)$, the space of level 1 automorphic forms of $O_n$ with coefficients in $U$ [CL19, §4.4.4]. As such it is equipped with an action of the (commutative) Hecke ring $H(O_n)$ of $O_n$ [CL19, §4.2.5 & §4.2.6]. For all $g \geq 1$, the space $\text{Alt}_g$ is canonically isomorphic to the dual of $M_{A^g V^*}(O_n)$, hence carries an $H(O_n)$-action as well. As an example, for any prime $p$ the Kneser $p$-neighbor operator is the endomorphism of $\text{Alt}_g$ sending $(L, \omega)$ to the sum of $(L', \omega)$ over the $L'$ in $\mathcal{L}_n$ with $L \cap L'$ of covolume $p$. The so-called Eichler commutations relations imply that the map $\Theta$ in (13) sends an $H(O_n)$-eigenvector on the left-hand side either to 0 or to a Siegel eigenform on the right-hand side (i.e. an $H(\text{Sp}_g)$-eigenvector): see [Fre82], as well as [Ral82] for an interpretation in terms of Satake parameters.

For $g = 8, 12, 16, 24$, the space $\text{Alt}_g$ has dimension 1, so it is generated by an $H(\text{Sp}_{2g})$-eigenvector. Our main theorem asserts that the image of $\text{Alt}_g$ under $\Theta$ is generated by $F_g$ and is nonzero. We have proved:

**Corollary 4.3.** For $g = 8, 12, 16, 24$, the Siegel modular form $F_g$ is an eigenform.

We now discuss the standard $L$-functions of the eigenforms $F_g$, or more precisely, their collections of Satake parameters. We need some preliminary remarks and notations mostly borrowed from [CL19, §6.4].

For any integer $n \geq 1$ we denote by $\mathcal{X}_n$ the set of sequences $c = (c_2, \ldots, c_p, \ldots, c_\infty)$, where the $c_p$ are semisimple conjugacy classes in $\text{GL}_n(\mathbb{C})$ indexed by the primes $p$, and where $c_\infty$ is a semisimple conjugacy class in $\text{M}_n(\mathbb{C})$. The direct sum and

\[^3\text{We have a similar definition with } O \text{ replaced by } SO \text{ that we will also use below.}\]
tensor product induce componentwise two natural operations \( \mathcal{X}_n \times \mathcal{X}_m \to \mathcal{X}_{n+m} \) and \( \mathcal{X}_n \times \mathcal{X}_m \to \mathcal{X}_{nm} \), denoted respectively \((c, c') \mapsto c \oplus c'\) and \((c, c') \mapsto cc'\). An important role will be played by the element \([n]\) of \( \mathcal{X}_n \) such that \([n]_p\) (resp. \([n]_{\infty}\)) has the eigenvalues \(\frac{p^{n-1} - 1}{2}i\) for \(i = 0, \ldots, n - 1\).

Any Siegel eigenform \( F \) for \( \text{Sp}_{2g}(\mathbb{Z}) \) has an associated collection of Satake parameters, semisimple conjugacy classes in \( \text{SO}_{2g+1}(\mathbb{C}) \) indexed by the primes, as well as an infinitesimal character (as defined by Harish-Chandra), which may be viewed as a semisimple conjugacy class in the Lie algebra of \( \text{SO}_{2g+1}(\mathbb{C}) \). So \( F \) gives rise to an element in \( \mathcal{X}_{2g+1} \) using the natural (or “standard”) representation \( \text{SO}_{2g+1}(\mathbb{C}) \to \text{GL}_{2g+1}(\mathbb{C}) \). This element is called the standard parameter of \( F \).

For \( g = 8, 12, 16, 24 \) we denote by \( \psi_g \) the standard parameter of the eigenform \( F_g \), and by \( \psi'_g \) that of a generator of \( M_{24}(\mathbb{Q}) = (\text{Alt}_{24}^6)^\ast \). By definition, \( \psi_g \) is in \( \mathcal{X}_{2g+1} \) and \( \psi'_g \) is in \( \mathcal{X}_{12} \).

Using Theorem 2, Rallis’s aforementioned theorem asserts
\[
\psi'_8 = \psi_8 \oplus [7] \quad \text{and} \quad \psi_9 = \psi'_9 \oplus [2g - 23] \quad \text{for} \quad g \geq 12.
\]

In the spirit of standard conjectures by Langlands and Arthur (see. [CL19, §6.4.4]), we will express those \( \psi_g \) and \( \psi'_g \) in terms of Satake parameters of certain cuspidal automorphic eigenforms for \( \text{GL}_m(\mathbb{Z}) \). The four following forms will play a role:

- For \( w = 11, 17 \), we denote by \( \Delta_w \in X_2 \) the collection of the Satake parameters, and of the infinitesimal character, of the classical modular normalized eigenform of weight \( w + 1 \) for \( \text{PGL}_2(\mathbb{Z}) \). For example, the \( p \)-th component of \( \Delta_{11} \) has determinant 1 and trace \( \tau(p)/p^{11/2} \). The eigenvalues of \( (\Delta_w)_\infty \) are \( \pm \frac{w}{2} \).

- For \( (w, v) = (19, 7) \) and \( (21, 13) \), and following [CL19, §9.1.3], there is a unique (up to scalar) cuspidal eigenform for \( \text{PGL}_4(\mathbb{Z}) \) whose infinitesimal character has the eigenvalues \( \pm w/2, \pm v/2 \); we denote by \( \Delta_{w,v} \in X_4 \) the collection of its Satake parameters, and of this infinitesimal character. As explained \textit{loc. cit.}, they are also the spinor parameters of generators of the 1-dimensional space of Siegel modular forms for \( \text{Sp}_4(\mathbb{Z}) \) with coefficients in the representations \( \text{Sym}^6 \Box \det^6 \) and \( \text{Sym}^{12} \Box \det^6 \) of \( \text{GL}_2(\mathbb{C}) \) respectively. See [CL19, Tables C3 & C.4] and [BCFvdG17] for more information on these Satake parameters.

**Theorem 4.4.** The parameters \( \psi_g \) and \( \psi'_g \) are given by the following table:

| \( g \) | 8         | 12        | 16        | 24        |
|--------|----------|-----------|-----------|-----------|
| \( \psi_g \) | \( \Delta_{21,13}[4] \oplus [4] \) | \( \Delta_{19,7}[6] \oplus [1] \) | \( \Delta_{17}[8] \oplus [9] \oplus [7] \oplus [1] \) | \( \Delta_{11}[12] \oplus [25] \) |
| \( \psi'_g \) | \( \Delta_{21,13}[4] \oplus [7] \oplus [1] \) | \( \Delta_{19,7}[6] \) | \( \Delta_{17}[8] \oplus [7] \oplus [1] \) | \( \Delta_{11}[12] \) |

**Proof.** By Proposition 7.5.1 of [CL19], relying on [Ike01] and [Wei86] or [Bö89], we have \( \psi'_{24} = \Delta_{11}[12] \), and thus \( \psi_{24} = \Delta_{11}[12] \oplus [25] \) by (15). The remaining
parameters are harder to determine, and at the moment we only know how to do it using Arthur’s results [Art13] together with [AMR, Taï19].

The irreducible representation $\Lambda^{12} V$ of $O(V)$ is the sum of two irreducible non-isomorphic representations $A^\pm$ of $SO(V)$. As a consequence, the two spaces $M_{A^\pm}(SO_{24})$ have dimension 1 and are isomorphic to $M_{A^{12}}(O_{24})$ as $H(O_{24})$-modules (see [CL19, §4.4.4]). The eigenvalues of $s = (\Delta_{19,7}[6])_\infty$ are $\pm i$ with $i = 1, \ldots, 12$, so $s$ is the image in $M_{24}(C)$ of the infinitesimal character of $A^\pm$. By Arthur’s multiplicity formula for $SO_{24}$, discussed in [CL19, Thm. 8.5.8] and which applies by [AMR, Taï19], there is an $H(O_{24})$-eigenvector in $M_{A^\pm}(SO_{24})$ with standard parameter $\Delta_{19,7}[6]$; this parameter must be $\psi_8'$ because we have $\dim M_{A^\pm}(SO_{24}) = 1$.

The two non-isomorphic representations $\Lambda^8 V$ and $\Lambda^{16} V$ of $O(V)$ have isomorphic and irreducible restriction $B$ to $SO(V)$. As a consequence, the space

$$M_B(SO_{24}) \simeq M_{A^8 V}(O_{24}) \oplus M_{A^{16} V}(O_{24})$$

has dimension 2 (see [CL19, §4.4.4]). Assume $\psi \in \mathcal{X}_{24}$ is either $\Delta_{21,13}[4] \oplus [7] \oplus [1]$ or $\Delta_{17}[8] \oplus [7] \oplus [1]$. The eigenvalues of $\psi_\infty$ are the $\pm i$ with $0 \leq i \leq 12$ and $i \neq 4$, so $\psi_\infty$ is the image in $M_{24}(C)$ of the infinitesimal character of $B$. An inspection of Arthur’s multiplicity formula for $SO_{24}$ [CL19, Thm. 8.5.8] shows that there is an $H(O_{24})$-eigenvector in $M_B(SO_{24})$ with standard parameter $\psi$. These two parameters are distinct and the isomorphism (16) is $H(O_{24})$-equivariant by [CL19, §4.4.4], it thus only remains to explain which of the two eigenvectors above belongs to $M_{A^8 V}(O_{24})$. But Arthur’s multiplicity formula for $Sp_{16}$ (or Ikeda’s results) shows that there is no cuspidal Siegel eigenform for $Sp_{16}(Z)$ with standard parameter $\Delta_{17}[8] \oplus [1]$, as explained in [CL19, Example 8.5.3]. This proves $\psi'_8 = \Delta_{21,13}[4] \oplus [7] \oplus [1]$ by (15), hence $\psi'_8 = \Lambda_{17}[8] \oplus [7] \oplus [1]$, and the whole table follows from (15) again. □
