Comparison of the Prevalence and Trend of Malnutrition between 0–6 Years and 7–11 Years Old Iranian Children: A Systematic Review and Meta-Analysis

Abstract
Background: To plan for decreasing the prevalence of malnutrition among children, reliable data of current status are required. The aim of the present cross-sectional study was to estimate the prevalence and trend of malnutrition among Iranian children. Methods: PubMed, ISI Web of Science, Scopus, Google Scholar, and Iranian databases including SID and Magiran were searched for studies published prior to October 2017 with MeSH terms of Malnutrition, Nutrition Disorders, Wasting, Stunting, Underweight, Undernutrition, Nutrition, Anthropometry, Weight, and Children and Iran. Three random effect models were applied to estimate the pooled prevalence of underweight, stunting, and wasting. Meta-regression and cumulative meta-analysis were performed. All analyses were also conducted separately for two different age groups including 0–6 years old (preschool) and 7–11 years old (primary school). Seventy-five studies (information of 1,069,815 individuals) were included in the final meta-analysis. Results: The overall prevalence of underweight, stunting, and wasting was estimated to be 8.4% [95% confidence interval (CI): 7.6–9.1], 14.5% (95% CI: 13.1–15.9) and 5.6% (95% CI: 5.0–6.2) in children age 0–6 years, and 6.6% (95% CI: 4.8–8.4), 7.3% (95% CI: 5.6–9.1), and 8.3% (95% CI: 6.1–10.7) in children age 7–11 years, respectively. Conclusions: The cumulative meta-analysis showed a decrease in the general trend of malnutrition in both preschool and primary school children of Iran. Stunting and wasting were the most common form of malnutrition in Iranian preschool and primary school children, respectively. The decreasing trend of malnutrition was much more noticeable about stunting.

Keywords: Child, growth disorders, Iran, malnutrition, stunting, underweight, wasting

Introduction
Lack of the provision of children’s nutritional needs inhibits optimal growth and development. As a result, malnutrition occurs which is a big challenge that nations face. Although the estimated global prevalence of malnutrition has shown a decline from the 1990s, it still affects a lot of people in low- and middle-income countries. According to the United Nations International Children’s Emergency Fund (UNICEF)/World Health Organization (WHO)/World Bank Group Joint Child Malnutrition Estimates in 2017, the worldwide prevalence of childhood stunting and wasting was 22.2% and 7.5%, respectively.[1] It has been estimated that 45% of deaths of children under 5 years of age are related to malnutrition.[2] Malnutrition also has long-term consequences such as poor physical and mental function, increased vulnerability to infections, developing noncommunicable diseases in adulthood, and economic burden for healthcare system.[3] Some of these effects can be persistent and irreversible.[4] Despite classification of Iran as an upper-middle income country by the World Bank and an increase in the number of overweight and obese children, malnutrition is still a problem in this country. In the UNICEF global nutrition report in 2016, Iran has been ranked 14th and 53rd regarding stunting and wasting among nearly 130 countries, respectively.[5] A national survey of the under-5-year Iranian children in 2010 showed that 5.7% were underweight, 10.13% were stunted, and the prevalence of wasting was 3.29%.[6]

Different factors may play roles in developing pediatrics malnutrition. Socioeconomic status, infectious diseases, maternal educational level, poor hygiene, and development.
and low health literacy are the most important factors determining undernutrition in children. Lack of access to health services, low education, poverty, food insecurity, and lack of nutritional knowledge have been proposed as main risk factors of malnutrition in Iran.

To plan for decreasing the prevalence of malnutrition among children, reliable data sources are required. The huge amount of all national information in this field should be summarized with a systematic review study. In addition, evaluating national trend of malnutrition can help policymakers to assess the effectiveness of interventional programs designed to solve the problem. Therefore, we conducted a systematic review and meta-analysis to determine the prevalence and trend of malnutrition in 0–6 years compared with 7–11 years old Iranian children. To the best of our knowledge, our study is comprehensive because (1) it covers two age groups of children, (2) it is based on all three indices of malnutrition (underweight, stunting, and wasting), and (3) it investigates the trend of malnutrition. According to our knowledge, there is no comprehensive study evaluating the trend of malnutrition among Iranian children.

**Methods**

**Study design and search strategy**

PubMed, ISI Web of Science, Scopus, Google Scholar, and English and Persian Iranian databases including SID and Magiran were searched for studies published prior to October 2017 with MeSH terms “malnutrition OR wasting OR wasted OR stunting OR stunted OR underweight OR undernutrition OR undernourished OR nutrition OR anthropometry OR weight OR height OR stature OR failure to thrive OR nutrition status” AND “children OR child OR childhood” AND “Iran.”

Based on the definition of the WHO, malnutrition in children is diagnosed when weight for age, height for age (HAZ), or weight for height (WHZ) z-scores are below 2 standard deviation compared with the international reference median value.

**Inclusion and exclusion criteria**

In addition to primary articles, articles’ references were also manually searched for additional studies. After excluding duplicates, the titles and abstracts of each article were reviewed independently by two of the authors for inclusion. The inclusion criteria were as follows: studies that were conducted in Iran (published articles in either Persian or English languages), participants less than 12 years, and classification of malnutrition according to the National Center for Health Statistics (NCHS)/WHO criteria.

The exclusion criteria were reported malnutrition using percentiles or percent of median (not based on the WHO definition of malnutrition), studies on nonhealthy children, and studies which their full-texts were not found after contacting their journal office. In cases of disagreement between two authors, the third author was consulted.

**Quality assessment and data extraction**

The quality of studies was assessed through “Quality Assessment Checklist for Prevalence Studies” (adapted from Hoy et al.). The total score of this checklist was categorized into three subgroups including low risk (0–3), moderate risk (4–6), and high risk (7–9) of bias. Studies with a low risk of bias were included in meta-analysis accordingly.

**Data analysis**

The variance of underweight, stunting, and wasting, as the three most commonly used anthropometric indices for the assessment of malnutrition in children, was computed using the binomial distribution formula in each study. Publication bias was evaluated through visual examination of funnel plots and through Egger’s test. The heterogeneity index among different studies calculated using tau square ($t^2$) test.

As the heterogeneity among studies was significant, three random effect models using Meta command in Stata was applied to estimate the pooled prevalence of underweight, stunting, and wasting. The effect of different variables as the source of the heterogeneity was investigated using meta-regression approach (quality score, mean age, age group, deprivation index, date of publication group, and sample size group were the variables that were included in the meta-regression approach). Cumulative meta-analysis was performed to evaluate the time-trend of each anthropometric index of children malnutrition after data sorting by publication date. The quality score of studies, mean age of participants, age group, sample size of studies, publication date, and deprivation index of cities were entered in meta-regression as independent variables. The sample size was categorized into extra small ($n < 200$), small ($n = 201–500$), medium ($n = 501–1000$), large ($n = 1001–10,000$), and extra-large ($n ≥ 10,000$). Publication date of studies was categorized into four groups: before 2000, 2000–2005, 2006–2011, and 2012–2017. Deprivation index of cities was determined according to Sheikh-Beiglou’s study in which cities have a score of 1–30 based on four methods used to measure the development level. All analyses were also conducted separately for two different age groups of target population including 0–6 years old (preschool) and 7–11 years old (primary school) and were compared. We used Stata version 11 (College Station, TX, USA) for conducting the analysis.

**Results**

**Summary of included studies**

Out of 513 identified studies through our search strategy, 75 studies (age group 0–6, 60; and age group 7–12, 15 studies) had our inclusion criteria and were included in the meta-analysis [Figure 1 and Table 1]. In total, the
information of 1,052,143 children age 0–6 years and 17,672 children age 7–11 years were considered in meta-analysis.

Meta-analysis

The overall prevalence of underweight was 8.1% [95% confidence interval (CI): 7.3–8.8], stunting was 13.1% (95% CI: 11.9–14.2), and wasting was 6.1% (95% CI: 5.5–6.6) in both age groups.

The corresponding figure in two subgroups of age is shown in Table 2, Figures 2a-f and 3. The results of meta-regression showed the date of publication (coefficient = −0.02; 95% CI: −0.04; −0.004) and deprivation index (coefficient = 0.002; 95% CI: 0.009–0.03) for underweight; the date of publication (coefficient = −0.06; 95% CI: −0.09, −0.03) for stunting; and the mean age of children in each age group (coefficient = 0.02; 95% CI: 0.009–0.03) and age group (coefficient = −0.09; 95% CI: −0.16, −0.02) for wasting were the main sources of the heterogeneity [Table 3].

Cumulative meta-analysis

The results of meta-regression and cumulative meta-analysis showed the significant decreasing trends of underweight and stunting in both age groups; however, the trend of wasting was decreasing but not significant. This trend was

WAZ=Weight for age, HAZ=Height for age, WHZ=Weight for height
This systematic review and meta-analysis was conducted on the published literature to estimate the prevalence of malnutrition among Iranian children. Totally, 75 published studies gained eligibility for inclusion in this review, most of which were published during the past decade. The national prevalence of underweight, stunting, and wasting in children age 0–6 years was as follows: 8.4%, 14.5%, and 5.6%. The corresponding figures for children age 7–11 years was 6.6%, 7.3%, and 8.3%. According to the reported statistics of malnutrition in neighboring countries of Iran including Turkey in 2008,[14] (underweight 2.8%, stunting 10.3%, and wasting 0.9%) and Pakistan in 2012,[13] (underweight 39.4%, stunting 63.9%, and wasting 17.9%), Iran represents an intermediate state. This variation could be related to the differences in risk factors of pediatrics malnutrition including short birth spacing, socioeconomic status, mother’s low level of education, and insufficient nutritional knowledge.[16]

more obvious in age group 0–6 years old. Moreover, the trend of reduction was more noticeable for stunting in both age groups [Table 3 and Figure 4a-f].

**Discussion**

This systematic review and meta-analysis was conducted on the published literature to estimate the prevalence of malnutrition among Iranian children. Totally, 75 published studies gained eligibility for inclusion in this review, most of which were published during the past decade. The national prevalence of underweight, stunting, and wasting in children age 0–6 years was as follows: 8.4%, 14.5%, and 5.6%. The corresponding figures for children age 7–11 years was 6.6%, 7.3%, and 8.3%. According to the reported statistics of malnutrition in neighboring countries of Iran including Turkey in 2008,[14] (underweight 2.8%, stunting 10.3%, and wasting 0.9%) and Pakistan in 2012,[13] (underweight 39.4%, stunting 63.9%, and wasting 17.9%), Iran represents an intermediate state. This variation could be related to the differences in risk factors of pediatrics malnutrition including short birth spacing, socioeconomic status, mother’s low level of education, and insufficient nutritional knowledge.[16]

**Table 2: Prevalence of underweight, stunting, and wasting in 0–6 and 7–11 years old Iranian children**

| Underweight % (95% CI) | 0–6 years | 7–11 years |
|------------------------|-----------|------------|
| 8.4 (7.6-9.1)          | 6.6 (4.8–8.4)|            |
| 14.5 (13.1-15.9)       | 7.3 (5.6-9.1) |            |
| 5.6 (5.6-6.2)          | 8.3 (6.0-10.7)|           |

CI=confidence interval
Interestingly, stunting was more prevalent among 0–6 years old children. This observed prevalence was higher than the World Bank data (7.1% in 2004)\textsuperscript{17} and lower than the global prevalence of stunting among children under 5 years of age (25% in 2013).\textsuperscript{18} In addition, compared with the latest WHO website statistics,\textsuperscript{1} our finding is more promising. Our findings confirm that stunting is the most common form of malnutrition in children below 6 years of age.\textsuperscript{18} Stunting is associated with higher morbidity and mortality rates, retardate physical and mental growth, and an increased risk of adulthood diseases.\textsuperscript{18} As stunting is reflective of chronic malnutrition, performing more accurate screening programs might result in achieving global nutrition targets for 2025.\textsuperscript{19}

In children age 7–11 years, wasting was more noticeable than underweight and stunting. In contrast to HAZ, WHZ is a measure of more acute malnutrition. This finding was comparable with a study in Nigeria by Adedeji \textit{et al}. In this study, the prevalence of thinness was 11.1%, underweight had a prevalence of 10.7%, and 10.1% of children were stunted.\textsuperscript{20} Inadequate intake of carbohydrate, having a large family size, and household food insecurity have been introduced as determinants of malnutrition in school children.\textsuperscript{21}
The results of cumulative meta-analysis can be interpreted in two ways: first, regarding the last line of cumulative meta-analysis result, the cumulative prevalence of underweight, stunting, and wasting was 6.5% (95% CI: 6.4–6.6), 6.9% (95% CI: 6.8–6.9), and 4.3% (95% CI: 4.2–4.4) in children age 0–6 years, and 3.4% (95% CI: 3.1–3.6), 5.3% (95% CI: 5.1–5.6), and 4.7% (95% CI: 4.4–4.9) in children age 7–11 years, respectively. Second, the general trend of malnutrition is decreasing in both preschool and primary school Iranian children; this is much more noticeable about stunting. Our results are comparable with the world trend in malnutrition. A decrease in the global prevalence of malnutrition has been reported from nearly 40% in 1990 to 25% in 2013. This illustrates Iran’s significant success in achieving global nutrition targets for 2025. This reduction was highly significant for Asian countries. According to the “first 1000 days theory,” failure to grow in the period between conception and child’s second birthday has a critical role in being stunted. So, our further reduction in stunting compared with wasting and underweight could be attributed to improved prenatal health cares.

**Limitation of Study**

This study can be considered as an important step in highlighting the extent of the problem by producing reliable data sources and help policymakers improve children nutrition policies. However, several limitations should be considered when interpreting our findings. Mentioned heterogeneity could confound the observed results. In addition, some studies included in the review did not report...
Figure 2d: Forest plot of the prevalence of stunting in 7–11 years old Iranian children

Figure 2e: Forest plot of the prevalence of wasting in 0–6 years old Iranian children
all malnutrition indicators, or few studies had presented their results divided by sex; therefore, we were unable to perform subgroup analysis by sex. Moreover, any potential misclassification bias is possible to have occurred in the results of included studies.

**Conclusions**

To the best of our knowledge, this systematic review is the first study that compared the pooled prevalence and trend of malnutrition between Iranian preschool and primary school children. Stunting and wasting were the most common form of malnutrition in Iranian preschool and primary school children, respectively. The general trend of malnutrition is decreasing in both preschool and primary school Iranian children; this is much more noticeable about stunting. In summary, the prevalence of malnutrition in Iran was in the lower limit of the global statistics. Higher number of stunted children under 5 years of age is an alarm for politicians to design preventive national programs for controlling chronic malnutrition.
