The inhibition of cellular toxicity of amyloid-β by dissociated transthyretin

Qin Cao, Daniel H. Anderson, Wilson Y. Liang, Joshua Chou, and Lorena Saelices

From the Departments of Biological Chemistry and Chemistry and Biochemistry, Molecular Biology Institute, University of California, Los Angeles, Los Angeles, California, USA, and the Center for Alzheimer’s and Neurodegenerative Diseases, Department of Biophysics, O’Donnell Brain Institute, University of Texas Southwestern Medical Center, Dallas, Texas, USA

The protective effect of transthyretin (TTR) on cellular toxicity of β-amyloid (Aβ) has been previously reported. TTR is a tetrameric carrier of thyroxine in blood and cerebrospinal fluid, the pathogenic aggregation of which causes systemic amyloidosis. However, studies have documented a protective effect of TTR against cellular toxicity of pathogenic Aβ, a protein associated with Alzheimer’s disease. TTR binds Aβ, alters its aggregation, and inhibits its toxicity both in vitro and in vivo. In this study, we investigate whether the amyloidogenic ability of TTR and its antiamyloid inhibitory effect are associated. Using protein aggregation and cytotoxicity assays, we found that the dissociation of the TTR tetramer, required for its amyloid pathogenesis, is also necessary to prevent cellular toxicity from Aβ oligomers. These findings suggest that the Aβ-binding site of TTR may be hidden in its tetrameric form. Aided by computational docking and peptide screening, we identified a TTR segment that is capable of altering Aβ aggregation and toxicity, mimicking TTR cellular protection. EM, immune detection analysis, and assessment of aggregation and cytotoxicity revealed that the TTR segment inhibits Aβ oligomer formation and also promotes the formation of nontoxic, nonamyloid amorphous aggregates, which are more sensitive to protease digestion. Finally, this segment also inhibits seeding of Aβ catalyzed by Aβ fibrils extracted from the brain of an Alzheimer’s patient. Together, these findings suggest that mimicking the inhibitory effect of TTR with peptide-based therapeutics represents an additional avenue to explore for the treatment of Alzheimer’s disease.

The physiological importance of transthyretin in Alzheimer’s disease was first reported by Schwarzman et al. in 1994 (1). One of the hallmarks of Alzheimer’s disease is the formation of brain plaques composed of β-amyloid peptide (Aβ). A 42-residue-long β-amyloid peptide (Aβ42) is the predominant variant in neuritic plaques of AD patients, with higher amyloidogenicity and cellular toxicity in vitro (2, 3). Many studies have shown that transthyretin (TTR) binds to Aβ, alters its aggregation, and inhibits its toxicity both in vitro and in vivo (4–8). In vitro, TTR co-aggregates with Aβ oligomers into large nontoxic assemblies, thereby inhibiting cellular toxicity (9, 10). In vivo, TTR sequesters Aβ and facilitates its clearance in the brain (1). More recently, the Buxbaum laboratory (6) showed that overexpression of WT human TTR suppressed disease progression in the APP23 transgenic AD mouse model. They also showed that silencing the endogenous TTR gene in AD transgenic mice accelerated Aβ42 deposition (5).

What makes the pair of TTR and Aβ42 particularly interesting is the amyloid nature of the two elements. In health, TTR functions as a transporter of retinol and thyroxine in blood, cerebrospinal fluid, and the eye and is secreted by the liver, choroid plexus, and retinal epithelium, respectively. However, dissociation of tetrameric TTR leads to amyloid fibril formation and systemic TTR amyloid deposition in patients of transthyretin amyloidosis (11–13). Whether the amyloidogenicity of TTR is linked to its interaction to Aβ42 is still under debate. Previous work showed that different aggregation propensities of TTR result in distinct interaction capabilities: fewer amyloidogenic variants had increased affinity for Aβ (7). However, this did not impact on the levels of inhibition of Aβ aggregation, and cytotoxicity protection was not assessed. Here we attempt to fill the experimental gap by studying the protective effect of TTR variants at different aggregated states over Aβ42 cellular toxicity. In addition, we show the identification and characterization of a segment of TTR that binds Aβ42 triggering the formation of nonamyloid amorphous aggregates that are more sensitive to protease digestion, therefore mimicking TTR inhibitory effect over Aβ42.

Results

We first evaluated the protection against Aβ42 cytotoxicity by nine TTR variants with distinct aggregation propensities in several aggregated states (Table 1). The amyloidogenic behavior of three representative TTR variants is shown in Fig. 1 (A and B). For this assay, recombinant transthyretin was incubated at 37 °C, pH 4.3; protein aggregation was followed by immunodot blot of the insoluble fractions collected by centrifugation at several time points (Fig. 1A); and EM was performed after 4 days of incubation (Fig. 1B). We found that M-TTR, a monomeric-engineered form of transthyretin that is soluble at physiological pH (14), shows notable aggregation after 1 day of incubation at pH 4.3 (Fig. 1, A–C). NSTTR is an artificially mutated variant of TTR carrying the double mutation N99R/S100R that, although remaining tetrameric in solution (Fig. 1C), shows a slower aggregation pattern than M-TTR (Fig. 1, A and B). T119M is a very stable mutant that did not show any sign of aggregation in 4 days (Fig. 1, A–C). Consistently, T119M results

TTR protection of amyloid-\(\beta\) cytotoxicity

in a significant delay of the onset of hereditary neuropathic TTR amyloidosis in patients who carry both \(tttr-V30M\) and \(tttr-T119M\) genes (15). We then incubated A\(\beta\)42 with the samples obtained from Fig. 1A for 16 h and evaluated its cytotoxicity by following MTT reduction. Three observations were made.

The first observation is that once aggregated, TTR does not prevent \(A\beta\)42 toxicity, for any of the variants (Fig. 1D). In addition, the variant NSTTR, which aggregates at a slow pace, resulted to be cytoprotective longer than M-TTR (Fig. 1D). The third observation is that T119M, which does not dissociate and aggregate, does not prevent toxicity either (Fig. 1D). We observed the same phenomena when the other six TTR variants were evaluated (Fig. S1). Although variants S112I, M13R/L17R, or A108R/L110R are mainly monomeric or dimeric in solution, the cytotoxic protection at day 0 is not greater than NSTTR or L55P that are mainly tetrameric in solution (Fig. 1C and Fig. S1B). This finding suggests that the capacity to protect from \(A\beta\)42 toxicity does not correlate with the initial oligomeric state of soluble variants (Fig. 1C and Fig. S1B) but rather with the dissociation state at the moment of the co-incubation with \(A\beta\)42 (Fig. 1, A and B, and Fig. S1C). A control experiment shows that the TTR variants used in this assay were not cytotoxic in the absence of \(A\beta\)42, with the exception of M-TTR, which resulted in a 20% reduction of cell viability (Fig. S1D).

Overall, our results indicate that dissociation of TTR is required for the inhibition of \(A\beta\) cytotoxicity. In addition, the data suggest that a more stable dissociated TTR exerts more \(A\beta\)42 inhibition than a more amyloidogenic variant. These findings led us to wonder whether a segment of TTR that is only exposed when dissociated but not in the aggregate might be similarly capable of altering \(A\beta\) toxicity.

Table 1

| TTR variant | Mutation | Oligomeric state in solution |
|-------------|----------|------------------------------|
| M-TTR       | F87M/L110M | Monomer                      |
| NSTTR       | N99R/S100R | Tetramer                      |
| T119M       | T119M     | Tetramer                      |
| WT          | None      | Tetramer                      |
| A108R/L110R | A108R/L110R | Tetramer + dimer + monomer   |
| M13R/L17R   | M13R/L17R | Dimer + monomer              |
| S112I       | S112I     | Tetramer                      |
| L55P        | L55P      | Tetramer                      |
| L55P/T119M  | L55P/T119M | Tetramer                     |

Figure 1. The inhibition of \(A\beta\)42 cytotoxicity by TTR depends on the aggregation propensity of each TTR variant. A, aggregation assay of three TTR variants followed by immunodot blot of insoluble fractions collected prior to incubation or after 1, 2, and 4 days of incubation at 37\(^\circ\) C, as labeled. All samples were treated equally and onto the same membrane. Cropping was applied for ethetical reasons. B, electron micrographs of aggregated TTR variants after 4 days of incubation. Scale bar, 200 nm. C, size-exclusion chromatography of soluble TTR variants at pH 7.4. D, cytotoxicity assay of \(A\beta\)42 in the presence of TTR variants at different stages of aggregation, followed by MTT reduction. A 5-fold molar excess of soluble TTR (50 \(\mu\)M, considering monomeric concentration) and aggregated samples collected after 1, 2 and 4 days of incubation were added to soluble 10 \(\mu\)M \(A\beta\)42 and incubated overnight. The samples were added to HeLa cells, and MTT reduction was measured after 24 h. Buffer-treated cells were considered 100% viability and used for normalization \((n = 3)\). All replicates are shown. Error bars, S.D. **, \(p \leq 0.005\); ***, \(p \leq 0.0005\). N.D., significance not detected. These results suggest that the dissociation of the tetrameric TTR structure precedes \(A\beta\)42 cytotoxicity protection, whereas aggregated TTR does not exert any effect.
The peptide TTR(105–117) was found to be highly amyloidogenic. We first analyzed the amyloidogenicity of TTR sequence by ZipperDB, which measures the propensity of every six-residue segment to form amyloid fibrils (19, 20) (Fig. S2A). TTR predictions show that the region that contains this segment is highly prone to form amyloid structures. In fact, we found the segment TTR(105–117) and the shorter peptide TTR(106–117) to be amyloidogenic in solution (Fig. S2B), which may explain the lack of inhibitory effect in previous studies (21). In contrast to the amorphous aggregates generated by recombinant full-length TTR, these peptides form amyloid-like fibrils (Fig. S2B). We then explored several sequence modifications to increase solubility, by eliminating the first tyrosine or adding a charged tag to the N-terminal end. The sequences and names of all the analyzed peptides are listed in Table 2. We found that TTR(105–117) amyloidogenicity was fully hindered by the addition of a polyarginine tag (Fig. S2B).

The soluble tagged derivatives of the segment TTR(105–117) inhibited Aβ42 fibril formation (Fig. 3 and Figs. S3 and S4). We first evaluated the inhibitory effect of TTR-derived peptides over Aβ42 fibril formation in thioflavin T (ThT) assays (Fig. 3A and Fig. S3). Of all the peptides that we analyzed, the best Aβ42 inhibitory effect was obtained with TTR-S (sequence YTIAALLSPYYSRRRRR), which contains a four-arginine tag followed by TTR(105–117) (Fig. S3). After an incubation of 2 days, we analyzed the samples by EM and found that the addition of TTR-S promoted the formation of amorphous aggregates (Fig. 3B) that were not birefringent when stained with Congo red (Fig. 3C). Remarkably, we found that TTR-S also promoted the formation of amorphous species when incubated with preformed Aβ42 fibrils (Fig. 3B). These aggregates were also found to be thioflavin T−negative (Fig. 3A), and nonbirefringent when stained with Congo red (Fig. 3C). The structural characterization of Aβ42 amorphous aggregates by CD showed that the addition of TTR-S to preformed fibrils resulted in a significant structural shift from β to helical secondary motifs (Fig. 3D). Additionally, we found that this structural modification results in cytotoxicity protection (Fig. 4). HeLa, PC12, and SH-SY5YSY cells were subjected to Aβ42 clearance (Fig. 3A–D). We found that the addition of TTR-S results in a significant reduction of Aβ42 cellular toxicity. This protective effect may be explained by the inhibition of the formation of A11-positive oligomers as a result of the incubation with TTR-S (Fig. 3D). It is worth noting that the larger aggregates did not resolve in the SDS-PAGE gel.

Next we found that the binding of TTR-S to soluble and fibrillar Aβ42 alters their protease resistance. Others have shown that TTR increases Aβ42 clearance in vivo (1). We reasoned that the large assemblies that form upon binding to TTR might be more sensitive to proteolytic activity than amyloid fibrils, thereby facilitating clearance. This hypothesis would also explain the protective effect found in vivo (6). We explored this hypothesis by analyzing proteolytic sensitivity of TTR-S–derived amorphous aggregates (Fig. 5). We incubated soluble and fibrillar Aβ42 with TTR-S overnight and collected the insoluble fractions by centrifugation. The immunoblot of insoluble fractions showed that amorphous aggregates that result in vivo...
TTR protection of amyloid-β cytotoxicity

from the incubation of TTR-S with both soluble and fibrillar Aβ42 were easily digested by proteinase K after 1 h (Fig. 5, A and B). In contrast, Aβ42 fibrils showed a significantly higher resistance to proteinase K digestion. We included soluble Aβ42 in the assay as a control of proteolytic activity.

Finally, we evaluated TTR-S ability to hinder amyloid seeding caused by fibrils extracted from the brain of an AD patient (Fig. 5C). The extraction of Aβ fibrils was performed by several cycles of homogenization and ultracentrifugation as described by Tycko (22). Amyloid seeding was measured by thioflavin T fluorescence. As expected, we found that the addition of sonicated patient-derived fibrils to soluble Aβ42 resulted in the acceleration of fibril formation. In contrast, incubation with TTR-S resulted in inhibition of Aβ42 fibril formation even in the presence of patient-derived Aβ seeds.

Discussion

Our results indicate that the dissociation of the TTR tetramer is required to prevent cytotoxicity from Aβ oligomers. These results are consistent with the model proposed by Buxbaum and co-workers (16), in which dissociated TTR

Figure 3. Effect of TTR-S on both soluble and fibrillar Aβ42. A, ThT fluorescence was measured from samples containing 10 μM Aβ42 in the presence and absence of a 3-fold molar excess of TTR-S. TTR-S was added before incubation (green) or after 18 h of incubation (red). TTR-S alone (purple) and buffer (not shown) were used as negative controls (n = 4). All replicates are shown. For a complete assessment of Aβ42 inhibition by TTR-derived peptides, see Fig. S4. B, Electron micrographs of Aβ42 fibrils formed in the absence of inhibitor (top panel), Aβ42 amorphous aggregates formed when TTR-S was added after 18 h of incubation (middle panel), and Aβ42 amorphous aggregates formed when TTR-S was added prior to incubation (bottom). Scale bar, 400 nm. Insets, pictures of test tubes containing the same samples shown by EM but 10 times more concentrated. These pictures were taken after 30 min of incubation and reveal obvious precipitation upon addition of TTR-S. C, Congo red staining of samples shown in A under bright field (left panels) and polarized light (right panels). D, CD traces of Aβ42 fibrils, Aβ42 fibrils after addition of TTR-S, and soluble Aβ42 after addition of TTR-S. The table below shows the calculated percentage of various structural conformations: helix, β-stranded, and others (turns and unstructured). These analyses indicate that the TTR-derived peptide TTR-S inhibits Aβ42 aggregation and promotes the formation of nonamyloid amorphous aggregates.
monomers efficiently bind Aβ oligomers, which are thought to be responsible for cellular Aβ-associated toxicity (23). They also found that tetrameric TTR binds to soluble monomeric Aβ, thereby suppressing aggregation in vitro (16). Others have also found an association between genetic stabilization of transthyretin and decreased risk of cerebrovascular disease (24). Consistently, an additional study found that the stabilization of the tetrameric form of TTR promotes Aβ clearance in a mouse model of Alzheimer’s disease (25). In our study, we did not find any effect of tetrameric TTR on...

Figure 5. Evaluation of the inhibitory effect of TTR-S by protease digestion and amyloid seeding. A, anti-Aβ42 immunodot blot of Aβ42 aggregates after proteinase K digestion. Soluble Aβ42 and preformed fibrils were incubated with TTR-S. Half of the sample was subjected to centrifugation, and soluble (S) and insoluble (I) fractions were collected. Increasing concentrations of proteinase K were added to the other half of the sample and incubated at 37 °C for 1 h. The samples were analyzed by dot blot using E610 specific anti-Aβ42 antibody. As negative control, we included a sample with TTR-S alone. B, the signal was quantified using ImageJ and plotted as shown. This assay shows that Aβ42 amorphous aggregates generated after the addition of TTR-S are degraded by proteinase K more readily than Aβ42 fibrils. C, amyloid seeding assay followed by ThT signal. Soluble Aβ42 was incubated with AD ex vivo seeds in the presence or absence of TTR-S. Samples with only TTR-S, with only AD seeds, or with buffer were included as negative control. Note that the addition of TTR-S results in inhibition of Aβ42 seeding (n = 3). All replicates are shown.

Aβ42 cytotoxicity. For instance, the tetrameric nonamyloidogenic T119M variant did not inhibit Aβ42 cytotoxicity (Fig. 1). Consistently, the nonamyloidogenic variant L55P/T119M did not inhibit cytotoxicity, whereas the amyloidogenic L55P variant did (Fig. S1). Taken together, other studies and our results suggest that tetrameric TTR may be protective in vivo perhaps not by recruiting toxic oligomers, but by sequestering and promoting clearance of Aβ monomers. In contrast, dissociated TTR seems to inhibit Aβ cytotoxicity by binding to toxic oligomeric species triggering the formation of large nontoxic assemblies.

Using computational tools, we generated a TTR-derived peptide that inhibits Aβ42 fibril formation and cellular toxicity (Fig. 3). This TTR-derived peptide, called TTR-S, contains the highly amyloidogenic segment TTR(105–117) followed by a polyarginine tag (Fig. S3). Our results are consistent with previous NMR studies showing that the interaction of TTR residues Lys15, Leu17, Ile107, Ala108, Ala109, Leu110, Ala120, and Val121 with Aβ contributes to the inhibition of Aβ fibril formation in vitro (16). In addition, others have shown that the segment TTR(106–117), one residue shorter, was capable of binding Aβ when immobilized on a membrane (8). However, the same peptide was not effective inhibiting Aβ aggregation in solution (21), unless the peptide was made cyclic, therefore not amyloidogenic (26), probably because of the high amyloidogenicity of this segment (Fig. S3). In our study, we solubilized TTR (105–117) by adding a charged tag, which confers higher solubility and also hinders self-aggregation (Fig. S3). The addition of a polyarginine tag was sufficient to convert a highly amyloidogenic peptide into an inhibitor of Aβ42 cellular toxicity even at substoichiometric concentrations (Fig. 4A).

TTR-S inhibits Aβ42 oligomer formation while promoting the formation of nontoxic, nonamyloid, amorphous aggregates. Previous studies of the inhibition of Aβ cytotoxicity by TTR have revealed that TTR co-aggregates with Aβ oligomers into large nontoxic assemblies, thereby inhibiting cellular toxicity in vivo (28, 29). In contrast, we found that TTR-S inhibits amyloid formation (28, 29). Finally, we evaluated the inhibitory effect of TTR-S on Aβ amyloid seeding. As shown previously, we found that the addition of ex vivo fibril extracts to soluble Aβ accelerates fibril formation (28, 29). In contrast, we found that TTR-S inhibits amyloid seeding catalyzed by Aβ extracted from the brain tissue of an AD patient (Fig. 5C).

In summary, our results suggest that the dissociation of the TTR tetramer into monomers is required to prevent cytotoxicity from Aβ oligomers. In addition, we found that a segment derived from TTR, TTR-S, exerts antimyloid activity, thereby...
inhibiting Aβ42 cytotoxicity and amyloid seeding. We also found that TTR-S binds to soluble and fibrillar species, causing a structural rearrangement that leads to an increase of protease sensitivity. Finally, we found that TTR-S inhibits amyloid seeding catalyzed by Aβ fibrils extracted from the brain of an AD patient. Our results encourage further evaluation of the inhibitory effect of TTR-derived peptides by additional experimentation. Additional experiments may include independent cell death assays to confirm our MTT-based cytotoxicity assays and evaluation of the species that result from the inhibition of seeded polymerization by ex vivo fibrils using techniques such as EM imaging, CD, and protease digestion analysis. The present study represents an expansion of the current knowledge on the mechanism of protection of TTR over Aβ42 cellular toxicity and opens a potential therapeutic avenue.

Experimental procedures

Patients and tissue material

Post-mortem brain tissue from the occipital lobe of an 83-year-old female patient of Alzheimer’s disease was obtained from Dr. Vinters at the Pathology Department of the University of California, Los Angeles. The patient was previously evaluated for the presence of amyloid plaques by immunohistochemistry and pathologically diagnosed for Alzheimer’s disease. The University of California, Los Angeles Office of the Human Research Protection Program granted exemption from internal review board review because the specimen was anonymized.

Recombinant protein purification

TTR mutants were cloned and purified as previously described (18). Briefly, exponentially growing Escherichia coli RosettaTM(DE3)pLysS competent cells (Millipore) were treated with 1 mM of isopropyl β-d-thiogalactopyranoside for 3 h. Mutant TTR were purified by nickel-affinity chromatography using HisTrap columns (GE Healthcare), followed by gel-filtration chromatography using a HiLoad 16/60 Superdex 75 column (GE Healthcare) running on an AKTA FPLC system. β-Amyloid peptide (Aβ42) was overexpressed through E. coli recombinant expression system and was purified as reported previously (30). The fusion construct for Aβ42 expression contains an N-terminal His tag, followed by 19 repeats of Asn-Ala-Asn-Pro, TEV protease site, and the human Aβ42 sequence. Briefly, the fusion construct was expressed into inclusion bodies in E. coli BL21(DE3) cells. 8 M urea was used to solubilize the inclusion bodies. Fusion proteins were purified through HiTrap HP columns, followed by reversed-phase HPLC. After TEV cleavage, Aβ42 peptide was purified from the cleavage solution by reversed-phase HPLC followed by lyophilization. To disrupt preformed aggregation, lyophilized Aβ42 was resuspended in 100% hexafluoroisopropanol, which was finally removed by evaporation.

TTR protection of amyloid-β cytotoxicity

Size-exclusion chromatography with multiangle light scatter and refractometer detection

Components of 0.5-μg protein samples were separated by a silica-based size-exclusion column (Toso Biosep G3000SWXL; 5 μm beads, 7.8 × 300 mm with guard column). The elution buffer contained 0.025 M NaH2PO4, 0.1 M Na2SO4, 1 mM Na3VO4, which was weighed on an analytical scale, titrated together to pH 6.5 with NaOH, and diluted to final volume in a 2-liter volumetric flask. The flow rate was 0.4 ml/min. Samples were 0.1-μm filtered (Millipore UltraFree MC centrifugal filters). Each injection was 40–50 μl. The peaks were detected by UV absorbance at 280 nm (Waters 2487), light scatter, and index of refraction (Wyatt Technologies MiniDAWN and OPTILAB DSP). Molecular weights were calculated with Astra software, from the light scatter and refractometer signals, transferring the dn/dc and normalization parameters determined from the monomer peak of BSA.

TTR aggregation assay

TTR aggregation assays were performed as previously described (31). Briefly, 1 mg/ml TTR sample in 10 mM sodium acetate, pH 4.3, 100 mM KCl, and 10 mM EDTA was incubated at 37°C during a maximum of 7 days. Transmission EM micrographs were taken after 7 days of incubation. Insoluble fractions were sampled and used to follow TTR aggregation by immunodot blot.

Transmission EM

Transmission EM was performed to visualize TTR mutant aggregation and the fibrillation of Aβ42 in the presence of TTR mutants or TTR-derived inhibitors. 5 μl of solution was spotted onto freshly glow-discharged carbon-coated EM grids (Ted Pella, Redding, CA, USA). The grids were rinsed three times with 5 μl of distilled water after 3 min of incubation, followed by staining with 2% uranyl acetate for 2 min. A T12 Quick CryoEM electron microscope at an accelerating voltage of 120 kV was used to examine the specimens. The images were recorded digitally by a Gatan 2kX2k CCD camera.

Cell lines

HeLa, PC-12 Adh, and SH-SY5Y (catalog nos. CRL-2, CRL-1721.1, and CRL-2266, respectively; ATCC) cell lines were used for measuring the toxicity of Aβ42. HeLa cells were cultured in Dulbecco’s modified Eagle’s medium with 10% fetal bovine serum, PC-12 cells were cultured in ATCC-formulated F-12K medium (ATCC; catalog no. 30-2004) with 2.5% fetal bovine serum and 15% horse serum.

MTT-based cell assay

We performed MTT-based cell viability assay to assess the cytotoxicity of Aβ42 with or without the addition of TTR mutants or TTR-derived peptide inhibitors. A CellTiter 96 aqueous nonradioactive cell proliferation assay kit (MTT) (catalog no. G4100, Promega, Madison, WI, USA) was used. Prior to toxicity test, HeLa, PC-12, and SH-SY5Y cells were plated at 10,000, 15,000, and 10,000 cells/well, respectively, in 96-well
Thioflavin T fibrillation assay

The aggregation of His-tagged TTR mutants was followed by immunodot blot analysis as described by Saelices et al. (18) using SuperSignal® West HisProbe™ kit following the manufacturer’s instructions (Life Technologies). Briefly, 100 μl of samples was spun at 13,000 rpm for 30 min, and the pellet was resuspended in the same volume of fresh buffer and spun again. The final pellet was resuspended in 6 M guanidine chloride and dotted onto nitrocellulose membranes (0.2 μm, Bio-Rad). We used a concentration of the HisProbe antibody of 1:10,000. The aggregation of Aβ42 was followed by Western and immunodot blotting analysis. For the Western blots, 7.5 μl of 6 μm samples were separated by SDS-PAGE (NuPAGE 4–12% Bis-Tris gel, Life Technologies) or native gels (NativePAGE 4–16% Bis-Tris gel, Life Technologies) and transferred onto a nitrocellulose membrane (iBlot® 2 NC mini stacks, Life Technologies) by iBlot® 2 membrane transfer system (Life Technologies). For the immunodot blot analysis, 2–15-μl of samples were dotted onto a nitrocellulose membrane (Bio-Rad). We used concentrations of 6E10 antibody of 1:2000 (Biologend®) (33), OC antibody of 1:25,000, and A11 antibody of 1:500 (Millipore and Life Technologies, respectively) (34). The horseradish peroxidase–conjugated anti-mouse IgG antibody (Sigma–Aldrich) was used as secondary antibody at a concentration of 1:2000, and anti-rabbit IgG antibody (Thermo Scientific) was used to detect OC and A11 at a concentration of 1:1000. The membrane was finally developed using the SuperSignal® West Pico chemiluminescent substrate kit (Life Technologies), following the manufacturer’s instructions.

CD spectroscopy

Secondary structures of Aβ42 samples were analyzed by CD spectroscopy. The samples (200 μl) were placed into a 1-mm-path length quartz cell (Hēllma Analytics). A Jasco J-810 UV-visible spectropolarimeter was employed. The spectra were obtained in a wavelength range of 190–250 nm, with a time response of 2 s, a scan speed of 50 nm/min, and a step resolution of 0.1 nm. Each spectrum was the average of five accumulations. All of the samples were assayed at a concentration of 50 μg/ml in 15 mM phosphate buffer (pH 7.4). The spectra were recorded at 25° C. The results are expressed as the mean residue molar ellipticity,

$$\theta = \frac{\theta \times 100 \times M}{C \times l \times n}$$

where θ is the ellipticity in degrees, l is the optical path in cm, C is the concentration in mg/ml, M is the molecular mass, and n is the number of residues in of the sample molecule. The ellipticity of the samples of Aβ after addition of TTR-S was normalized by using the ellipticity of TTR-S as a blank. The percentage of the various structural conformations was calculated by using the software package CDPro, which includes three programs to determine the secondary structure fractions: CONTIN, SELCON, and CDSSTR (35). The results are displayed as the mean values and standard deviations of the three methods.

Proteinase K assay

Soluble Aβ42 was prepared in PBS and filtered (0.22 nm). Aβ42 fibrils were obtained after 1–2 weeks of incubation in PBS at room temperature. Three-fold molar excess of TTR-S was added to soluble or fibrillar Aβ42 and incubated for 16 h. Soluble and insoluble fractions were extracted by centrifugation of half of the sample prior to incubation. PK digestion was performed in a reaction volume of 100 μl containing 10 μM of Aβ42 samples and varying concentrations of PK (from 0.2 to 50
µg/ml) in 0.1 M Tris-HCl buffer, pH 7.5, for 1 h at 37°C. The reactions were quenched with 1 mM phenylmethylsulfonyl fluoride, and the samples were analyzed by dot blot using E610 specific anti-Aβ42 antibody. As negative control, we included a sample with TTR-S alone. The signal was quantified using ImageJ.

Statistical analysis

Statistical analysis of cell assays was performed with Prism 7 for Mac (GraphPad Software) using an unpaired t test. All samples were included in the analysis. All quantitative experiments are presented as independent replicates or as means ± S.D. of at least three independent experiments.

Data availability

The data sets and images used and/or analyzed during the current study are available from the corresponding author on reasonable request. All remaining data are contained within the article.

Acknowledgments—We thank Prof. David Eisenberg and Prof. Cong Liu for significant support. We also thank Dr. Harry V. Vinters for supplying the AD brain tissue and the patient who generously donated it.

Author contributions—Q. C. and L. S. data curation; Q. C. and L. S. validation; Q. C., D. H. A., W. Y. L., J. C., and L. S. investigation; L. S. conceptualization; L. S. formal analysis; L. S. supervision; L. S. funding acquisition; L. S. visualization; L. S. methodology; L. S. writing—original draft; L. S. project administration; L. S. writing—review and editing.

Funding and additional information—This work was supported by Amyloidosis Foundation Grants 20160759 and 20170827 (to L. S.) and the People Programme (Marie Curie Actions) of the European Union’s Seventh Framework Programme FP7/2007–2013 under Research Executive Agency Grant Agreement 298559 (to L. S.).

Conflict of interest—L. S. is a consultant for ADRx, Inc.

Abbreviations—The abbreviations used are: AD, Alzheimer’s disease; TTR, transthyretin; Aβ, amyloid-β peptide; Aβ42, amyloid-β peptide 1–42; ThT, thioflavin T; M-TTR, monomeric TTR variant; NSTTR, N98R/S99R TTR variant; MTT, 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide; TTR-S, TTR segment modified with a polyarginine tag; PDB, Protein Data Bank.
