Abstract

Lattice spin models in statistical physics are used to understand magnetism. Their Hamiltonians are a discrete form of a version of a Dirichlet energy, signifying a relationship to the Harmonic map heat flow equation. The Gibbs distribution, defined with this Hamiltonian, is used in the Metropolis-Hastings (M-H) algorithm to generate dynamics tending towards an equilibrium state. In the limiting situation when the inverse temperature is large, we establish the relationship between the discrete M-H dynamics and the continuous Harmonic map heat flow associated with the Hamiltonian. We show the convergence of the M-H dynamics to the Harmonic map heat flow equation in two steps: First, with fixed lattice size and proper choice of proposal size in one M-H step, the M-H dynamics acts as gradient descent and will be shown to converge to a system of Langevin stochastic differential equations (SDE). Second, with proper scaling of the inverse temperature in the Gibbs distribution and taking the lattice size to infinity, it will be shown that this SDE system converges to the deterministic Harmonic map heat flow equation. Our results are not unexpected, but show remarkable connections between the M-H steps and the SDE Stratonovich formulation, as well as reveal trajectory-wise out of equilibrium dynamics to be related to a canonical PDE system with geometric constraints.

1 Introduction

The Metropolis-Hastings (M-H) algorithm \cite{13} is widely used in particle statistics for model estimations \cite{23, 4, 21, 3, 22}. It constructs a discrete-time Markov chain to sample a desired probability distribution by accepting or rejecting proposed states. For applications in statistical physics, it is often the Gibbs or canonical distribution that is to be sampled. In this case, the algorithm accepts all the proposed new states with lower energy and often rejects the proposals with higher energy. Similar behavior can be obtained from a Langevin Stochastic differential equation (SDE) that performs gradient descent with noise; it too has the Gibbs distribution as its steady-state distribution. This suggests that the Langevin SDE might be the optimal M-H algorithm in which all proposals are accepted.

For certain forms of probability distributions, the diffusion limit and therefore optimal scaling, of the random walk M-H algorithm has been obtained in \cite{27, 5, 23}. Specifically, for product measures in \cite{27} and the Gibbs distribution of a lattice model in \cite{5}, the weak convergence to Langevin diffusions have been shown by comparing generator functions. For non-product form measures the weak convergence to a stochastic partial differential equation was shown in \cite{23}. These works consider the weak convergence only in equilibrium. Subsequent works \cite{15, 14} consider scaling limits of out of equilibrium systems approaching equilibrium.

To address the question of trajectory-wise convergence, we study the XY and the classical Heisenberg lattice spin models \cite{28} that play an important role in statistical physics to understand phase transitions and other phenomena including superconductivity \cite{20, 7}. The XY and classical Heisenberg models are defined on a periodic d-dimensional lattice $T_d$ with $\delta x = \frac{1}{N}$ the distance between adjacent vertices. Each spin sits at a lattice point and is described by a unit vector $\sigma_i : T_d \rightarrow S^n$, where $n = 1$ for the XY model and $n = 2$ for the classical Heisenberg model. The Hamiltonian of the system,

$$H = J \sum_{\langle i, j \rangle} \| \sigma_i - \sigma_j \|^2,$$

(1)

gives energy to misaligned neighboring spins where $\langle i, j \rangle$ represents nearest neighbors and $J = N^{2-d}$ is a scaling factor. Denote $\sigma$ as the total spin configuration of $\sigma_i, i \in T_d$, the M-H algorithm accepts/rejects based on the Gibbs distribution defined as

$$\rho(\sigma) = Z^{-1} \exp(-\beta H(\sigma)),$$

(2)

where $\beta = (k_B T)^{-1}$ is the inverse temperature and $Z$ is the normalizing factor (aka partition function). The distribution is unaware of the confining geometry that the spins must remain in $S^n$. Rather, it is included in the proposal step of the M-H algorithm. As the nearest neighbor coupling is encoded in $H$, it follows naturally from our analysis here that with no accept/reject step each spin behaves like a Brownian motion on the surface of $S^n$. It follows similarly from our analysis in the proof. Since the XY model and the classical Heisenberg model are widely used to study superconductors and ferromagnets, their critical properties are of interest. Asymptotic results on the total spin of the mean-field XY and classical Heisenberg models have been studied by large deviation theory and Stein’s method in \cite{17, 18}. Numerically, Monte Carlo methods are used to verify analytical results about XY model in \cite{22, 3} and classical Heisenberg model in \cite{26, 6}.

We will show the M-H algorithm applied to the above lattice system produces equivalent trajectories to the overdamped Langevin equation,

$$d\sigma_i = P_{\sigma_i}^\perp (\Delta_N \sigma_i) dt + P_{\sigma_i}^\perp \left( \sqrt{\frac{2N}{\beta}} dW_t \right),$$

(3)

(interpreted in the Stratonovich sense) in the limit of small perturbations to create the proposal where

$$\Delta_N \sigma_i = -N^2 (2\sigma_i - \sigma_{i+1} - \sigma_{i-1}),$$
is the discrete Laplacian and $P^+(x) = y - (x \cdot y)x$ for $\|x\| = 1$ is the projection of $y$ onto the tangent plane of $x$. The Stratonovich understanding of (3) is essential to keep the $\sigma_i$ as unit vectors, and for more on this equation see [1]. Under the Itô understanding, an Itô correction term will drop out in (3) and show naturally in the proof in section 3. This system is the Langevin system that performs gradient descent on the energy defined by (1) with the added constraint that $\sigma_i$ is confined to $S^n, n = 1, 2$. In $S^2$, the classical Heisenberg model, this system is an SDE representation of the overdamped Landau-Lifshitz-Gilbert equation that has the Gibbs distribution as its invariant measure [19].

Taking the number of lattice points, $N$, to infinity or equivalently the lattice spacing $\delta x = \frac{1}{N}$ to zero, the limit of the deterministic part of (3) is the partial differential equation (PDE) called the harmonic map heat flow equation

$$\partial_t \sigma = P^+(\Delta \sigma).$$

In the $S^2$ case, (3) is in the form of the overdamped Landau-Lifshitz equation [9]

$$\partial_t \sigma = -\sigma \times (\sigma \times \Delta \sigma).$$

In [10] this Landau-Lifshitz equation was shown to be equivalent to the Harmonic map heat flow from $T^d \to S^2$. With the scaling $J = N^{2-d}$, the Hamiltonian in (1) is the discrete form of the Dirichlet energy, $\int_\Omega |\nabla \sigma|^2 d\Omega$, for this harmonic map heat flow. This suggests that by decreasing the temperature, the out of equilibrium dynamics of the M-H algorithm converge to the deterministic flow of (5) with large $N$ for the classical Heisenberg model. We will show this equivalence by showing the convergence of the system of SDE (3) to the PDE (1) in the limit of large $N$ with an appropriate scaling of the temperature to zero with $N$.

One method to obtain the deterministic limit of a stochastic system is to consider the hydrodynamic limit with relative entropy bound [11, 30, 8]. Due to the geometric constraint in XY and classical Heisenberg model, it is difficult to calculate the averages with respect to the Gibbs states as in [11, 30, 8] if the spin is expressed in Cartesian coordinates. One might try to use polar coordinates to do window averaging but the potential is not convex as in [8]. Since the hydrodynamic limit for XY and classical Heisenberg model are not fully understood, we choose an alternative way of taking inverse temperature $\beta$ to infinity along with particle number $N \to \infty$.

One difficulty in the proof comes from the constraint of the spins staying as unit vectors. This requires a normalising step in the M-H algorithm and makes the calculation complicated. We take the Taylor expansion of the M-H step and approximate it as a linear step. This truncation of the spin vector does not stay on the sphere but the error for the subsequent steps is shown to converge in the limit as $N \to \infty$ with our system size dependent choice of parameters. Moreover, in the weak convergence result of M-H dynamics to diffusion process [27, 5, 23], the assumption of equilibrium is essential to bound the error terms. The result here only assumes that we are starting the M-H dynamics (and thus the SDE system) from a deterministic initial condition satisfying a certain regularity condition and then evolving into equilibrium. To bound the error terms, the scaling chosen here is worse than in the previously mentioned papers and is likely not be optimal. We will use numerical simulations to explore how tight these bounds appear to be.

The remainder of the paper is as follows. In Section 2 we present the main results in two parts. First, the convergence of M-H dynamics to the SDE system (3) as the proposal size of M-H step goes to zero is stated, then the convergence of the SDE system (3) to the deterministic PDE (4) as the lattice size goes to infinity and temperature to zero is stated. The key steps of the proof are given in Sections 3 and 4 for the more complicated classical Heisenberg model from $T^1 \to S^2$ with details appearing in the Appendix. The proof for XY model follows similarly. For the M-H to SDE (3) proof in Section 3 we apply a similar approach as in [23], by first Taylor expanding the M-H step, keeping only the first three terms, then computing the required conditional expectations with respect to the Gaussian random variables to obtain the drift and diffusion terms of an Euler step for the diffusion process. Then, the difference between the M-H and SDE dynamics in $L^2$ norm is bounded by a Grönwall inequality. For the SDE (3) to PDE (5) proof in Section 4 we compare the SDE system with the finite difference approximation of the Landau-Lifshitz equation. The difference between the SDE and ODE system is governed by another diffusion process. We will rescale this process and show the rescaled error is bounded for a long time using stopping time. These convergence results are supported by numerical simulations of the systems in Section 5. Conclusions are presented in Section 6.

**Remark 1.1.** We only show the case $T^1 \to S^2$. The calculation could be generalised for other cases of $T^d \to S^2$ quite similarly.

2 Main Results

In this section we will explain how we apply M-H algorithm to the XY and classical Heisenberg models, and state our main results. Our first result is that the M-H dynamics is close to a stochastic Euler scheme for the SDE (3) in Itô understanding. The bound on the error between the M-H dynamics and the SDE (3) is accomplished using arguments similar to the convergence of the stochastic Euler method. Our second result bounds the error between the SDE system and the finite difference approximation of the harmonic map heat flow equation (4).

2.1 Metropolis-Hastings step

Here, we explicitly state the M-H dynamics for XY and classical Heisenberg models we consider with Hamiltonian given by (1) for the case $d = 1$.

Consider a set of spins evolving in time, $\sigma^n_{i}$ for particle $i = 1 \ldots N$ and time step $n \geq 0$ with time step size $\delta t$. To create the proposal, take the normal random vector $w^n_i = \left( z_1 \begin{array}{c} z_2 \end{array} \right)$, with $z_1, z_2 \sim \mathcal{N}(0, 1)$ for the XY model and three-dimensional normal random vector $w^n_i = \left( \begin{array}{c} z_1 \\ z_2 \\ z_3 \end{array} \right)$, with $z_1, z_2, z_3 \sim \mathcal{N}(0, 1)$, for the classical Heisenberg model. Then project to the tangent plane of $\sigma^n_i$ to get the random vector $\nu^n_i = \mathcal{P}_\perp \sigma^n_i (w^n_i)$.

Since we are trying to get a trajectory-wise convergence result, it is convenient to embed the M-H algorithm and the SDE dynamics in the same probability space. To this end, we define $w^n_i = W_i((n + 1)\delta t) - W_i(n\delta t) / \sqrt{\delta t}$, where $W_i, 1 \leq i \leq N$ are the Brownian motion in (3). At time step $n$ the proposal for next time step is

$$\tilde{\sigma}^n_i = \exp_{\sigma^n_i}(\varepsilon \nu^n_i), \quad 1 \leq i \leq N,$$

with $\exp_{\sigma^n_i}$ the exponential map and $\varepsilon$ the proposal size. The values $\sigma^n$ and $\tilde{\sigma}^n$ are used to denote the total spin configuration $\sigma^n_{i}, 1 \leq i \leq N$ at time step $n$ and the total proposal spin configuration $\tilde{\sigma}^n_{i}, 1 \leq i \leq N$.

The proposal $\tilde{\sigma}^n$ is accepted with probability

$$\alpha = 1 \wedge e^{-\beta \delta H},$$

and rejected otherwise, where

$$\delta H = H(\tilde{\sigma}^n) - H(\sigma^n) = \sum_{j=1}^{N} \frac{\partial H}{\partial \sigma^n_j} \cdot (\tilde{\sigma}^n_j - \sigma^n_j) + 2J \sum_{j=1}^{N} (\tilde{\sigma}^n_j - \sigma^n_j) \cdot (\tilde{\sigma}^n_j - \sigma^n_j) - J \sum_{j=1}^{N} (\tilde{\sigma}^n_j - \sigma^n_j) \cdot (\tilde{\sigma}^n_{j+1} - \sigma^n_{j+1} + \tilde{\sigma}^n_{j-1} - \sigma^n_{j-1})$$
is the difference between the Hamiltonian of the proposal \( \tilde{\sigma}^n \) and of the current spin configuration \( \sigma^n \). Then
\[
\sigma^{n+1} = \kappa_n \tilde{\sigma}^n + (1 - \kappa_n) \sigma^n, \quad \kappa_n \sim \text{Bernoulli}(\alpha(\tilde{\sigma}^n, \sigma^n)).
\]

Repeating this step, we create a discrete Markov process at time steps \( n + 1, n + 2, \ldots \) and we will show the convergence of the Markov chain to the solution to the Langevin SDE system (3).

**Remark 2.1.** In fact, either choice of the following projection gives us the same result for the classical Heisenberg model
\[
P_{\tilde{\sigma}^n}^{\perp}(w^n_i) = \begin{cases} 
\sigma^n_i \times w^n_i \\
-\sigma^n_i \times (\sigma^n_i \times w^n_i) = w^n_i - \sigma^n_i (\sigma^n_i)^T w^n_i
\end{cases}
\]
as both lead to random walk on the sphere (see Appendix C).

### 2.2 Convergence of Metropolis dynamics to SDE system

First we are going to show the convergence from M-H dynamics to Langevin SDEs with fixed number of particles \( N \) as the proposal size \( \varepsilon \to 0 \). Intuitively, using the Taylor series truncation of the proposal, the approximation of one M-H step leads to an expression that looks like one Euler step for simulating the SDE in Itô sense.

Let \( F_t \) denote the filtration generated by the Brownian motion \( W_i \) in (3) and Bernoulli random variables \( \kappa_n \) at \( n\delta t \), we denote the conditional expectation \( \mathbb{E}[: F_{n\delta t}] \) by \( \mathbb{E}_n [:] \).

The drift over one step of the Metropolis-Hastings algorithm for the \( i \)-th particle for small \( \varepsilon \) is approximated by
\[
\mathbb{E}_n [\sigma_i^{n+1} - \sigma_i^n] \approx -\frac{1}{2} \beta \varepsilon^2 P_{\sigma_i^n}^{\perp} \left( \frac{\partial H}{\partial \sigma_i^n} \right) - \varepsilon^2 \sigma_i^n. \tag{9}
\]
where \( P_{\sigma_i^n}^{\perp} = I - \sigma_i^n (\sigma_i^n)^T \) is the projection onto the tangent plane of \( \sigma_i^n \).

Denoting the noise contribution over one step as
\[
\Gamma_i^n \equiv \sigma^{n+1}_i - \sigma_i^n - \mathbb{E}_n [\sigma^{n+1}_i - \sigma_i^n], \tag{10}
\]
it is approximated by
\[
\Gamma_i^n \approx \varepsilon \nu_i^n = \varepsilon P_{\sigma_i^n}^{\perp} (w_i^n). \tag{11}
\]
Thus, one step of the Metropolis-Hastings algorithm is approximately given by
\[
\sigma_i^{n+1} - \sigma_i^n \approx -\frac{1}{2} \beta \varepsilon^2 P_{\sigma_i^n}^{\perp} \left( \frac{\partial H}{\partial \sigma_i^n} \right) - \varepsilon^2 \sigma_i^n + P_{\sigma_i^n}^{\perp} (\varepsilon w_i^n). \tag{12}
\]
Defining \( \beta \varepsilon^2 = N \delta t \) where \( \delta t \) is the time step size, the above equation changes to
\[
\sigma_i^{n+1} \approx \sigma_i^n - \frac{1}{2} N P_{\sigma_i^n}^{\perp} \left( \frac{\partial H}{\partial \sigma_i^n} \right) \delta t - \frac{N}{\beta} \sigma_i^n \delta t + P_{\sigma_i^n}^{\perp} \left( \sqrt{\frac{N}{\beta}} w_i^n \sqrt{\delta t} \right). \tag{13}
\]
Since \( \frac{\partial H}{\partial \sigma_i^n} = 2J(2\sigma_i^n - \sigma_{i+1}^n - \sigma_{i-1}^n) \) and \( J = N \) when \( d = 1 \), the above is the Euler step for the Langevin SDE (3) in Itô interpretation
\[
d\sigma_i = P_{\sigma_i^n}^{\perp} (\Delta_N \sigma_i) dt - \frac{N}{\beta} \sigma_i dt + P_{\sigma_i^n}^{\perp} \left( \sqrt{\frac{N}{\beta}} dW_i \right). \tag{14}
\]
This intuitive idea leads to the first result:

**Theorem 2.1.** Define the piecewise constant interpolation of M-H dynamics as \( \tilde{\sigma}_i(t) \),
\[
\tilde{\sigma}_i(t) = \sigma_i^n \quad n\delta t \leq t < (n + 1)\delta t, \tag{15}
\]
and $\sigma_i(t)$ as the solution for the Langevin SDE system \((14)\) with initial condition $\|\sigma_i(0)\| = 1, 1 \leq i \leq N$. If we think of the proposal in M-H step coming from the noise $\varepsilon w_n^i = \sqrt{N\beta^{-1}} [W_i((n + 1)\delta t) - W_i(n\delta t)]$, then we have the following strong convergence result:

$$
E \left[ \sup_{0 \leq s \leq t} \|\sigma_i(s) - \tilde{\sigma}_i(s)\|^2 \right] \leq C_1 \sqrt{\delta t} \exp(C_2 T), \quad t \in [0, T], 1 \leq i \leq N, \tag{16}
$$

for any $T \in (0, \infty)$, where $C_1, C_2$ are functions of $N, \beta, J, T$ and independent of the choice of $i$ and $\delta t$.

**Remark 2.2.** The equation \((14)\) is equivalent to the SDE in Stratonovich sense \((5)\) which gives $d\|\sigma_i\|^2 = 2\sigma_i \cdot d\sigma_i = 0$ to make $\sigma_i$ stay on the unit sphere.

**Remark 2.3.** Theorem 2.1 is a trajectory-wise convergence result.

### 2.3 Convergence of SDE system to the Landau-Lifshitz equation

Notice in the SDE \((14)\), if $\beta$ is chosen to be $\beta = N\gamma$, $\gamma > 1$, formally the noise part disappears with $N \to \infty$. This gives the idea of the second result:

**Theorem 2.2.** For the harmonic map heat flow equation \((14)\) with periodic boundary condition and initial condition satisfying

$$
\|\sigma(\cdot, 0)\| = 1, ||\nabla\sigma(\cdot, 0)|| \leq \lambda, \tag{17}
$$

for some $\lambda$ as in \((10)\), the solution exists and is smooth. Denote the finite difference approximation of \((14)\) as

$$
d\tilde{\sigma}_i = P_{\tilde{\sigma}_i}^\perp(\Delta_N \tilde{\sigma}_i), \quad \|\tilde{\sigma}_i\| = 1, \tag{18}
$$

and $\|\tilde{\sigma}_i(t) - \sigma(i\delta x, t)\| \to 0$ on any fixed time interval where the solution remains well defined, when the space discretization $\delta x = \frac{1}{N}$ goes to zero \([22]\) Theorem 1).

For any $0 < p < \frac{3}{2}$, there exist a constant $\gamma > 1, \beta = N\gamma$ and constants $C_1, C_2$ independent of $N$, such that if

$$
\left( \left( \frac{N}{\beta} \right)^{1-p} T + C_1 \frac{1}{N} \left( \frac{N}{\beta} \right)^{1-2p} \right) e^{C_2 T} \leq 1,
$$

then the difference between the SDE \((14)\) and the finite difference approximation \((18)\) has the following bound

$$
E \left[ \sup_{0 \leq s \leq t} \frac{1}{N} \sum_{i=1}^N \|\sigma_i(s) - \tilde{\sigma}_i(s)\|^2 \right] \leq \left( \frac{N}{\beta} \right)^{p/2}, \quad t \in [0, T]. \tag{19}
$$

As $\gamma > 1, \frac{N}{\beta}$ is small when $N$ is large, so the difference between the SDE system and finite difference approximation of the PDE is bounded by a small term for a long time $T$ that goes to $\infty$ with $N \to \infty$. The solution for PDE is smooth so the finite difference approximation is close to the PDE solution as shown in \([20]\).

**Remark 2.4.** The choice of $\gamma$ depends on $p$ with the following relation

$$
\left( \frac{N}{\beta} \right)^{p/2} \leq 1.
$$

For a uniform bound in $0 \leq t \leq T$, we need $p < \frac{1}{2}$ so $\gamma > 13$. For a bound with some fixed $t \in [0, T]$, we only need $p < 1$ and $\gamma > 7$. We do not believe this bound is sharp for the convergence result at all, which will be addressed in Section 4 when we perform numerical simulations of these models. We find that $\gamma = \frac{3}{2}$ is enough to see convergence in our numerical simulations.
3 Metropolis-Hastings dynamics to SDE system

In this section the convergence of the M-H algorithm to the SDE (14) for the classical Heisenberg model will be shown by calculating the drift and diffusion of one M-H step, which is approximately a stochastic Euler step for (14). Then the error estimation of stochastic Euler’s method is used to give a bound on the difference between M-H and SDE dynamics with proposal size $\varepsilon \to 0$. Here the basic steps are outlined, the detail of error estimation is given in Appendix A.

Remark 3.1. The proof for the XY model will be similar, one only needs to change the random vector $\nu_i$ on the tangent plane as a two-dimensional vector.

3.1 Set-up

In the calculation to follow, we have the following assumptions and notations.

The number of the particles $N$ on unit length is fixed and the limiting case $\varepsilon \to 0$ is considered. We have $\beta, J$ as functions of $N$ so they are also regarded as constant.

In the calculation, the proposal $\tilde{\sigma}_i^n$ is approximated by normalizing $\sigma_i^n + \varepsilon \nu_i^n$ 

$$\tilde{\sigma}_i^n = \exp_{\sigma_i^n}(\varepsilon \nu_i^n) \approx \frac{\sigma_i^n + \varepsilon \nu_i^n}{\|\sigma_i^n + \varepsilon \nu_i^n\|}.$$ 

By Taylor expanding $\frac{\sigma_i^n + \varepsilon \nu_i^n}{\|\sigma_i^n + \varepsilon \nu_i^n\|}$, the proposal $\tilde{\sigma}_i^n$ can be approximated by order $\varepsilon$ and $\varepsilon^2$ expansion

$$\tilde{\sigma}_i^n \approx \sigma_i^n + \varepsilon \nu_i^n,$$

$$\tilde{\sigma}_i^n \approx \sigma_i^n + \varepsilon \nu_i^n - \frac{1}{2} \varepsilon^2 (\nu_i^n \cdot \nu_i^n) \sigma_i^n. \quad (20)$$

The proof of the following Lemma is shown in Appendix A.

Lemma 3.1. Denote

$$a_i^n \equiv \tilde{\sigma}_i^n - \frac{\sigma_i^n + \varepsilon \nu_i^n}{\|\sigma_i^n + \varepsilon \nu_i^n\|},$$

$$c_i^n \equiv \tilde{\sigma}_i^n - (\sigma_i^n + \varepsilon \nu_i^n),$$

$$d_i^n \equiv \tilde{\sigma}_i^n - (\sigma_i^n + \varepsilon \nu_i^n - \frac{1}{2} \varepsilon^2 (\nu_i^n \cdot \nu_i^n) \sigma_i^n).$$

Then $E \left[\|a_i^n\|^k\right] \leq A_k \varepsilon^k, E \left[\|c_i^n\|^k\right] \leq C_k \varepsilon^{2k}$ and $E \left[\|d_i^n\|^k\right] \leq D_k \varepsilon^{3k}$.

Using the approximation (21), $\delta H$ in (8) can be written as

$$\delta H = \varepsilon \frac{\partial H}{\partial \sigma_i^n} \cdot \nu_i^n + R_i^n + h_i^n \approx O(\varepsilon),$$

$$R_i^n \equiv \varepsilon \sum_{j \neq i} \frac{\partial H}{\partial \sigma_j^n} \cdot \nu_j^n \approx O(\varepsilon),$$

$$h_i^n \equiv \sum_j \frac{\partial H}{\partial \sigma_j^n} \cdot c_j^n + 2J \sum_j \delta \sigma_j^n \cdot \delta \sigma_j^n - J \sum_j \delta \sigma_j^n \cdot (\delta \sigma_{j+1}^n + \delta \sigma_{j-1}^n) \approx O(\varepsilon^2), \quad (21)$$

and we only keep the $\varepsilon$ term in $\delta H$ in the following calculation so $\delta H$ is approximated by a normal random variable. We are going to show the calculation for one specific particle $i$ so we take $i$-th term $\frac{\partial H}{\partial \sigma_i^n} \cdot \nu_i^n$ and the summation of $j \neq i$ terms as a single term $R_i^n$. 

7
3.2 Drift

Proposition 3.1. Let \( \{\sigma^n\} \) be the Markov chain given by the Metropolis-Hastings algorithm, and \( \{\sigma^n_i\} \) the spin for i-th particle at time step n. Then

\[
\mathbb{E}_n [\sigma_i^{n+1} - \sigma_i^n] = - \frac{1}{2} \beta \varepsilon^2 P_{\sigma_i^n} \left( \frac{\partial H}{\partial \sigma_i^n} \right) - \varepsilon^2 \sigma_i^n + \theta_i^n,
\]

where the error term

\[
\theta_i^n = \mathbb{E}_n [\sigma_i^{n+1} - \sigma_i^n] - \left( - \frac{1}{2} \beta \varepsilon^2 P_{\sigma_i^n} \left( \frac{\partial H}{\partial \sigma_i^n} \right) - \varepsilon^2 \sigma_i^n \right)
\]

satisfies \( \mathbb{E} \left[ \| \theta_i^n \|^2 \right] \leq C \varepsilon^6 \).

In the calculation we keep the order \( \varepsilon^2 \) term. The remainder is order \( \varepsilon^3 \) and will be shown to be bounded in the error estimation for M-H and SDE dynamics. The basic steps are given in the following calculation, for details of the error estimation see Appendix A.

Since \( \sigma_i^{n+1} = \exp_{\sigma_i^n} (\varepsilon \nu_i^n) \) with probability \( 1 + e^{-\beta H} \) and stay \( \sigma_i^n \) otherwise,

\[
\mathbb{E}_n [\sigma_i^{n+1} - \sigma_i^n] = \mathbb{E}_n \left[ \left( \exp_{\sigma_i^n} (\varepsilon \nu_i^n) - \sigma_i^n \right) (1 + e^{-\beta H}) \right]
\]

\[
\approx \mathbb{E}_n \left[ \left( \varepsilon \nu_i^n - \frac{\varepsilon^2}{2} (\nu_i^n \cdot \nu_i^n) \sigma_i^n + d_i^n \right) (1 + e^{-\beta H}) \right]
\]

\[
= \varepsilon \mathbb{E}_n [\nu_i^n (1 + e^{-\beta H})] - \frac{\varepsilon^2}{2} \mathbb{E}_n [(\nu_i^n \cdot \nu_i^n) \sigma_i^n (1 + e^{-\beta H})] + \mathbb{E}_n [d_i^n (1 + e^{-\beta H})].
\]

We drop the third term in the last line of (24) as it is an \( \varepsilon^3 \) term:

\[
\mathbb{E} \left[ \| d_i^n (1 + e^{-\beta H}) \| \right] \leq \mathbb{E} \left[ \| d_i^n \| \right] \leq C \varepsilon^3,
\]

since \( 0 < |1 + e^{-\beta H}| < 1 \).

For the second term in the last line of (24), since \( 1 + e^{-\beta H} \approx 1 + O(\varepsilon) \) we have that

\[
\frac{\varepsilon^2}{2} \mathbb{E}_n [(\nu_i^n \cdot \nu_i^n) \sigma_i^n (1 + e^{-\beta H})] = \mathbb{E}_n \left[ \frac{\varepsilon^2}{2} (\nu_i^n \cdot \nu_i^n) \sigma_i^n \right] + O(\varepsilon^3) = \varepsilon^2 \sigma_i^n + O(\varepsilon^3).
\]

This corresponds to the Itô correction for (3).

The first term in the last line of (24) is the most difficult one to approximate. Using the notation in (21)

\[
1 + e^{-\beta H} = 1 + e^{-\beta (\varepsilon \frac{\partial H}{\partial \sigma_i^n} \nu_i^n + R_i^n)} \approx 1 + e^{-\beta (\varepsilon \frac{\partial H}{\partial \sigma_i^n} \nu_i^n + R_i^n)} + O(\varepsilon^2),
\]

since \( h_i^n \approx O(\varepsilon^2) \), we write it as

\[
\mathbb{E}_n \left[ \varepsilon \nu_i^n \left( 1 + e^{-\beta (\varepsilon \frac{\partial H}{\partial \sigma_i^n} \nu_i^n + R_i^n)} \right) \right] + O(\varepsilon^3).
\]

For any orthonormal basis \( \{b_1, b_2, b_3\} \) in \( \mathbb{R}^3 \), the normal random vector \( w_i^n \) can be expressed as

\[
w_i^n = (w_i^n \cdot b_1) b_1 + (w_i^n \cdot b_2) b_2 + (w_i^n \cdot b_3) b_3
\]

and \((w_i^n \cdot b_1), (w_i^n \cdot b_2), (w_i^n \cdot b_3)\) are independent standard normal random variables. Denote \( r_1 = (w_i^n \cdot b_1), r_2 = (w_i^n \cdot b_2), r_3 = (w_i^n \cdot b_3) \), \( w_i^n = r_1 b_1 + r_2 b_2 + r_3 b_3 \). Choose \( b_1, b_2 \) two orthonormal vectors on the tangent plane of \( \sigma_i^n \) and \( b_3 = \sigma_i^n \),

\[
\nu_i^n = P_{\sigma_i^n} (w_i^n) = r_1 b_1 + r_2 b_2,
\]

where \( r_1, r_2 \sim \mathcal{N}(0, 1) \) are independent. Then,

\[
\mathbb{E}_n \left[ \varepsilon \nu_i^n \left( 1 + e^{-\beta (\varepsilon \frac{\partial H}{\partial \sigma_i^n} \nu_i^n + R_i^n)} \right) \right] = \mathbb{E}_n \left[ \varepsilon r_1 \cdot b_1 \left( 1 + e^{-\beta (\varepsilon \frac{\partial H}{\partial \sigma_i^n} b_1 + \varepsilon r_2 \frac{\partial H}{\partial \sigma_i^n} b_2 + R_i^n)} \right) \right] + \mathbb{E}_n \left[ \varepsilon r_2 \cdot b_2 \left( 1 + e^{-\beta (\varepsilon \frac{\partial H}{\partial \sigma_i^n} b_1 + \varepsilon r_3 \frac{\partial H}{\partial \sigma_i^n} b_3 + R_i^n)} \right) \right].
\]

The two terms on the right are similar in form so we only show the calculation for the first one and the second one follows similarly.
Remark 3.2. For the XY model, the projection of the normal random vector onto the tangent plane of $\sigma_i^n$ is represented by the form $r_i b_1$, where $r_i \sim N(0,1)$. The other parts of the calculation basically stays the same.

Using tower property of conditional expectation for the first term on the RHS of (25), we have

$$
E_n \left[ \varepsilon r_1 b_1 \left( 1 + e^{-\beta \left( \varepsilon r_1 \frac{\partial H}{\partial \sigma_i^n} b_1 + \varepsilon r_2 \frac{\partial H}{\partial \sigma_i^n} b_2 + R_i^n \right) } \right) \right] = E_n \left[ E_n \left[ \varepsilon r_1 b_1 \left( 1 + e^{-\beta \left( \varepsilon r_1 \frac{\partial H}{\partial \sigma_i^n} b_1 + \varepsilon r_2 \frac{\partial H}{\partial \sigma_i^n} b_2 + R_i^n \right) } \right) \mid r_2, R_i^n \right] \right].
$$

We recall the following Lemma 2.4 in [23]. (See also [27].)

**Lemma 3.2.** For $z \sim N(0,1)$,

$$
E \left[ z \left( 1 + e^{az+b} \right) \right] = ae^{\frac{a^2}{2}} + b \Phi \left( -\frac{b}{|a|} - |a| \right),
$$

for any real constants $a, b$, and $\Phi(\cdot)$ is the CDF for the standard normal random variable.

The proof of this Lemma is the direct result for the integration for the expectation. And the Lemma gives

$$
E_n \left[ \varepsilon r_1 b_1 \left( 1 + e^{-\beta \left( \varepsilon r_1 \frac{\partial H}{\partial \sigma_i^n} b_1 + \varepsilon r_2 \frac{\partial H}{\partial \sigma_i^n} b_2 + R_i^n \right) } \right) \mid r_2, R_i^n \right] = -\beta \varepsilon^2 \left( \frac{\partial H}{\partial \sigma_i^n} b_1 \right) b_1 e^{-\frac{b^2}{2}} - \beta \varepsilon^2 \left( \frac{\partial H}{\partial \sigma_i^n} b_2 \right) b_2 - \beta R_i^n \Phi \left( \frac{\varepsilon r_2 \frac{\partial H}{\partial \sigma_i^n} b_2 + R_i^n}{\varepsilon \frac{\partial H}{\partial \sigma_i^n} b_1} \right) - \beta \varepsilon \frac{\partial H}{\partial \sigma_i^n} \cdot b_1.
$$

Before taking the expectation over $r_2$, we further simplify this expression by noting that $e^{O(\varepsilon)} = 1 + O(\varepsilon)$ resulting in

$$
E_n \left[ \varepsilon r_1 b_1 \left( 1 + e^{-\beta \left( \varepsilon r_1 \frac{\partial H}{\partial \sigma_i^n} b_1 + \varepsilon r_2 \frac{\partial H}{\partial \sigma_i^n} b_2 + R_i^n \right) } \right) \mid r_2, R_i^n \right] 
\approx \left( -\beta \varepsilon^2 \left( \frac{\partial H}{\partial \sigma_i^n} b_1 \right) b_1 + O(\varepsilon^3) \right) \Phi \left( \frac{\varepsilon r_2 \frac{\partial H}{\partial \sigma_i^n} b_2 + R_i^n}{\varepsilon \frac{\partial H}{\partial \sigma_i^n} b_1} \right) + O(\varepsilon).
$$

For a mean zero Gaussian random variable $z$, we know

$$
E \left[ \Phi(z) \right] = E \left[ \Phi(z) - \frac{1}{2} + \frac{1}{2} \right] = \int_{-\infty}^{\infty} \left( \Phi(z) - \frac{1}{2} + \frac{1}{2} \right) p(z) dz = \frac{1}{2},
$$

as $\Phi(z) - \frac{1}{2}$ is an odd function and the probability density function $p(z)$ is even.

Notice that $R_i^n = \varepsilon \sum_{j \neq i} \frac{\partial H}{\partial \sigma_j^n} \cdot \nu_j^n$ is a sum of independent mean zero Gaussian random variables, so $\varepsilon r_2 \frac{\partial H}{\partial \sigma_i^n} \cdot b_2 + R_i^n$ is a Gaussian random variable with mean 0, therefore

$$
E_n \left[ -\beta \varepsilon^2 \left( \frac{\partial H}{\partial \sigma_i^n} b_1 \right) b_1 \Phi \left( \frac{\varepsilon r_2 \frac{\partial H}{\partial \sigma_i^n} b_2 + R_i^n}{\varepsilon \frac{\partial H}{\partial \sigma_i^n} b_1} \right) \right] = \frac{1}{2} \beta \varepsilon^2 \left( \frac{\partial H}{\partial \sigma_i^n} \cdot b_1 \right) b_1.
$$

The second term on the RHS of (23) follows similarly,

$$
E_n \left[ \varepsilon r_2 b_2 \left( 1 + e^{-\beta \left( \varepsilon \frac{\partial H}{\partial \sigma_i^n} b_1 + \varepsilon r_2 \frac{\partial H}{\partial \sigma_i^n} b_2 + R_i^n \right) } \right) \right] = -\frac{1}{2} \beta \varepsilon^2 \left( \frac{\partial H}{\partial \sigma_i^n} \cdot b_2 \right) b_2 + O(\varepsilon^3).
$$

Combining the above

$$
E_n \left[ \sigma_i^{n+1} - \sigma_i^n \right] \approx -\frac{1}{2} \beta \varepsilon^2 P_{\sigma_i^n} \left( \frac{\partial H}{\partial \sigma_i^n} \right) - \varepsilon^2 \sigma_i^n,
$$

where $\frac{\partial H}{\partial \sigma_i^n} = \frac{1}{N^2} \Delta N \sigma_i^n$ and $\Delta N \sigma_i^n = N^2 (\sigma_{i+1}^{n} + \sigma_{i-1}^{n} - 2 \sigma_i^n)$ denotes the discrete Laplacian.
3.3 Diffusion

Recall $\Gamma_i^n$ in (10).

\[
\Gamma_i^n = \begin{cases} 
\varepsilon \nu_i^n + c_i^n - \mathbb{E}_n [\sigma_i^{n+1} - \sigma_i^n] & \text{with probability } \alpha \\
-\mathbb{E}_n [\sigma_i^{n+1} - \sigma_i^n] & \text{with probability } 1 - \alpha
\end{cases}
\]

with accept rate $\alpha$ in (7). Since $\mathbb{E}_n [\sigma_i^{n+1} - \sigma_i^n]$ is an order $\varepsilon^2$ term and $\alpha \approx 1$ with small $\varepsilon$, we are going to show

\[
\Gamma_i^n \approx \varepsilon \nu_i^n.
\]

**Proposition 3.2.** The diffusion term

\[
\Gamma_i^n = \sigma_i^{n+1} - \sigma_i^n - \mathbb{E}_n [\sigma_i^{n+1} - \sigma_i^n] = \varepsilon \nu_i^n + \phi_i^n,
\]

where

\[
\phi_i^n = \Gamma_i^n - \varepsilon \nu_i^n = \sigma_i^{n+1} - \sigma_i^n - \mathbb{E}_n [\sigma_i^{n+1} - \sigma_i^n] - \nu_i^n
\]

is a random variable with mean $\mathbb{E} [\phi_i^n] = 0$, variance $\mathbb{E} [\|\phi_i^n\|^2] \leq C \varepsilon^3$, and covariance $\mathbb{E} [\phi_i^n \cdot \phi_i^m] = 0$ for $n \neq m$.

**Proof.** For the mean

\[
\mathbb{E} [\phi_i^n] = \mathbb{E} [\sigma_i^{n+1} - \sigma_i^n - \mathbb{E}_n [\sigma_i^{n+1} - \sigma_i^n] - \varepsilon \nu_i^n],
\]

then $\mathbb{E} [\phi_i^n] = 0$. For the variance,

\[
\mathbb{E} [\|\phi_i^n\|^2] = \mathbb{E} \left[ \left\| \exp_{\sigma_i^n} (\varepsilon \nu_i^n) - \sigma_i^n - \mathbb{E}_n [\sigma_i^{n+1} - \sigma_i^n] - \varepsilon \nu_i^n \right\|^2 (1 - e^{-\beta \delta H}) \right] + \mathbb{E} \left[ \left\| \varepsilon \nu_i^n - \mathbb{E}_n [\sigma_i^{n+1} - \sigma_i^n] \right\|^2 (1 - (1 - e^{-\beta \delta H})) \right] \tag{31}
\]

The first term in the last line of (31)

\[
\mathbb{E} \left[ \left\| \sigma_i^n - \mathbb{E}_n [\sigma_i^{n+1} - \sigma_i^n] \right\|^2 (1 - e^{-\beta \delta H}) \right] \leq \mathbb{E} \left[ \left\| \sigma_i^n - \mathbb{E}_n [\sigma_i^{n+1} - \sigma_i^n] \right\|^4 \right]^{\frac{1}{2}} \mathbb{E} \left[ \left(1 - e^{-\beta \delta H} \right)^2 \right]^{\frac{1}{2}} \leq C \varepsilon^4,
\]

as $\mathbb{E}_n [\sigma_i^{n+1} - \sigma_i^n] = -\frac{\beta}{2} \varepsilon^2 \Delta \mathbb{P}_{\sigma_i^n} \left( \frac{\partial H}{\partial \sigma_i^n} \right) - \varepsilon^2 \sigma_i^n + O(\varepsilon^3)$ and $\mathbb{E} [\|c_i^n\|^4] \leq C \varepsilon^8$ shown in Appendix A.

For the second term in the last line of (31), since $\left| 1 - (1 - e^{-\beta \delta H}) \right| = \left| e^0 - e^{0 \wedge (-\beta \delta H)} \right| \leq |\beta \delta H|$, we observe

\[
\mathbb{E} \left[ \left\| \varepsilon \nu_i^n - \mathbb{E}_n [\sigma_i^{n+1} - \sigma_i^n] \right\|^2 (1 - (1 - e^{-\beta \delta H})) \right] \leq \mathbb{E} \left[ \left\| \varepsilon \nu_i^n - \mathbb{E}_n [\sigma_i^{n+1} - \sigma_i^n] \right\|^4 \right]^{\frac{1}{2}} \mathbb{E} \left[ \|\delta H\|^2 \right]^{\frac{1}{2}} \leq C \varepsilon^3,
\]

for some constant $C$, since $-\varepsilon \nu_i^n - \mathbb{E}_n [\sigma_i^{n+1} - \sigma_i^n] = -\varepsilon \nu_i^n + O(\varepsilon^2)$ and $\delta H = \varepsilon \sum_j \frac{\partial H}{\partial \sigma_j} \nu_j^n + O(\varepsilon^2)$ are both order $\varepsilon$ term.

Combining the above, the variance in (31) is bounded by $\mathbb{E} [\|\phi_i^n\|^2] \leq C \varepsilon^3$.

For the covariance of $\phi_i^n, \phi_i^m$ at different time steps $n > m$, and $\zeta = x, y, z$ denotes the coordinates of the vector,

\[
\mathbb{E} \left[ \phi_i^n \phi_i^m \right] = \mathbb{E} \left[ \mathbb{E}_n [\phi_i^n \phi_i^m] \right] = \mathbb{E} \left[ \phi_i^n \mathbb{E}_n [\phi_i^m] \right] = \mathbb{E} \left[ \phi_i^n \phi_i^m \right] = 0.
\]

**Remark 3.3.** In fact, the error term is $\mathbb{E} \left[ \|\phi_i^n\|^2 \right] \sim O(\varepsilon^3)$ and this determines the order of the convergence in Theorem 2.4. The detail of calculation is given in Appendix A.3.
3.4 Error Estimation

For the error estimation, we apply similar techniques as in the proof of stochastic Euler’s method.

Take \( \sigma_i, \tilde{\sigma}_i \) as in Theorem 2.1. For simplicity we denote \( \mu_i(\sigma) = \mathbb{P}_{\gamma_i}^t(\Delta_N \sigma_j) - \frac{N}{\sqrt{N}} \sigma_i, \psi_i(\sigma) = \sqrt{N} \beta (1 - \sigma_i \sigma_j^T) \) the coefficients in (14). When \( N, J, \beta \) are fixed and \( ||\sigma|| = 1 \), the coefficient \( \mu, \psi \) are Lipschitz continuous in each coordinates of \( x \). From Theorem 5.2.1 in [25], the SDE system has a unique solution.

Now we have the following estimate on the error.

**Proposition 3.3.** Define the error \( e(t) \) between M-H interpolation \( \tilde{\sigma}_i \) and SDE (14) solution \( \sigma_i \) as

\[
e(t) = \sup_{1 \leq i \leq N, 0 \leq s \leq t} \mathbb{E} \left[ ||\sigma_i(s) - \tilde{\sigma}_i(s)||^2 \right].
\]

(32)

For any fixed \( T > 0 \), \( e(t) \) is bounded by

\[
e(t) \leq C(N, J, \beta, T) \sqrt{\delta t} \quad t \in [0, T].
\]

(33)

**Proof.** For the proof we are going to show \( e(t) \) satisfies the Grönwall inequality (\( C_i \) denotes some constant bound):

\[
e(t) \leq (C_1T + C_2) \int_0^t e(s)ds + \left( C_3 \sqrt{\delta t} + C_4 \delta t + C_5 \delta t^2 \right),
\]

so \( e(t) \leq \left( C_3 \sqrt{\delta t} + C_4 \delta t + C_5 \delta t^2 \right) \exp(C_1T(T + C_2)). \)

Since \( \tilde{\sigma}_i(t) = \sigma_i \left( \frac{t}{\delta t} \right) = \sigma_i + \sum_{j=0}^{[\frac{t}{\delta t}]-1} \left( \sigma_j^{i+1} - \sigma_j^i \right) \) and both \( \sigma_i, \tilde{\sigma}_i \) start from the same initial condition, from definition of \( e(t) \) and \( \theta_i^\nu \) in (23), \( \Gamma_i^\nu \) in (10), \( \phi_i^\nu \) in (30):

\[
e(t) = \sup_{1 \leq i \leq N, 0 \leq s \leq t} \mathbb{E} \left[ ||\sigma_i(s) - \tilde{\sigma}_i(s)||^2 \right]
= \sup_{1 \leq i \leq N, 0 \leq s \leq t} \mathbb{E} \left[ \left\| \int_0^s \mu_i(\sigma(u))du + \int_0^s \psi_i(\sigma(u))dW_i(u) - \sum_{j=0}^{[\frac{s}{\delta t}]-1} \left( \mathbb{E} \left[ \sigma_j^{i+1} - \sigma_j^i \right] + \Gamma_j^\nu_i \right) \right\|^2 \right]
= \sup_{1 \leq i \leq N, 0 \leq s \leq t} \mathbb{E} \left[ \left\| \int_0^s \mu_i(\sigma(u))du + \int_0^s \psi_i(\sigma(u))dW_i(u) - \sum_{j=0}^{[\frac{s}{\delta t}]-1} \left( \mu_i(\sigma^j)\delta t + \varepsilon \nu_i^j + \theta_i^\nu_j + \phi_i^\nu_j \right) \right\|^2 \right]
\]

(35)

where \( \mu_i(\sigma^j)\delta t = \int_{\delta t}^{(j+1)\delta t} \mu_i(\sigma(u))du \) and \( \varepsilon
nu_i^j = \int_{\delta t}^{(j+1)\delta t} \psi_i(\sigma(u))dW_i \). Applying Hölder’s inequality and \( \mathbb{E} \left[ |X + Y|^2 \right] \leq 2 \mathbb{E} \left[ |X|^2 + |Y|^2 \right] \) produces

\[
e(t) \leq C \sup_{1 \leq i \leq N, 0 \leq s \leq t} \mathbb{E} \left[ \left\| \int_0^{[\frac{s}{\delta t}]} \mu_i(\sigma(u))du \right\|^2 + \left\| \int_0^{[\frac{s}{\delta t}]} \left( \psi_i(\sigma(u)) - \psi_i(\tilde{\sigma}(u)) \right) dW_i \right\|^2 \right.
+ \left\| \int_0^{[\frac{s}{\delta t}]} \mu_i(\sigma(u))du \right\|^2 + \left\| \int_0^{[\frac{s}{\delta t}]} \psi_i(\sigma(u))dW_i \right\|^2 + \left\| \sum_{j=0}^{[\frac{s}{\delta t}]-1} \theta_i^j \right\|^2 + \left\| \sum_{j=0}^{[\frac{s}{\delta t}]-1} \phi_i^\nu_j \right\|^2 \right].
\]

(36)

Using Hölder inequality for the first term in (36) with the coordinate \( \zeta = x, y, z \)

\[
\left\| \int_0^{[\frac{s}{\delta t}]} \mu_i,\zeta(\sigma(u)) - \mu_i,\zeta(\tilde{\sigma}(u))du \right\|^2 \leq \int_0^{[\frac{s}{\delta t}]} \left( \mu_i,\zeta(\sigma(u)) - \mu_i,\zeta(\tilde{\sigma}(u)) \right)^2 du \int_0^{[\frac{s}{\delta t}]} 1^2 du,
\]

and
since $\mu_t$ is Lipschitz,
\[
\int_0^t (\mu_{i,\zeta}(\sigma(u)) - \mu_{i,\zeta}(\bar{\sigma}(u)))^2 du \leq C_1 \int_0^t (\sigma_{i,\zeta}(u) - \bar{\sigma}_{i,\zeta}(u))^2 du,
\]

combine $\zeta = x, y, z$ terms,
\[
\sup_{1 \leq i \leq N, 0 \leq s \leq t} \mathbb{E} \left[ \left\| \int_0^t \mu_i(\sigma(u)) - \mu_i(\bar{\sigma}(u)) du \right\|^2 \right] \leq C_1 t \int_0^t e(s) ds.
\]

Applying Itô isometry to the second term of (36) for the $x$ coordinate
\[
\mathbb{E} \left[ \left( \int_0^t \left( \psi(x(u)) - \psi(x(u)) \right) dW_i(u) \right)^2 \right]_x
\]
\[
= \mathbb{E} \left[ \left( \int_0^t \left( \bar{\sigma}_x^i dW_i^x + \bar{\sigma}_y^i dW_i^y + \bar{\sigma}_z^i dW_i^z \right)^2 \right) \right]
\]
\[
= \mathbb{E} \left[ \left( \int_0^t \left( \bar{\sigma}_x^i \bar{\sigma}_x^i dW_i^x + \bar{\sigma}_y^i \bar{\sigma}_y^i dW_i^y + \bar{\sigma}_z^i \bar{\sigma}_z^i dW_i^z \right)^2 \right) \right]
\]
\[
= \mathbb{E} \left[ \left( \int_0^t \left( (\bar{\sigma}_x^i)^2 - (\sigma_t^x)^2 \right)^2 du + \int_0^t (\bar{\sigma}_x^i \bar{\sigma}_x^i - \sigma_t^x \sigma_t^x)^2 du + \int_0^t (\bar{\sigma}_x^i \bar{\sigma}_x^i - \sigma_t^x \sigma_t^x)^2 du \right) .
\]

Since
\[
((\bar{\sigma}_x^i)^2 - (\sigma_t^x)^2)^2 \leq (|\bar{\sigma}_x^i| + |\sigma_t^x|)^2 (\bar{\sigma}_x^i - \sigma_t^x)^2 \leq 4(\bar{\sigma}_x^i - \sigma_t^x)^2,
\]
\[
(\bar{\sigma}_x^i \sigma_t^y - \sigma_t^x \sigma_t^y)^2 = (\bar{\sigma}_x^i - \sigma_t^x)(\bar{\sigma}_x^i - \sigma_t^y)^2 \leq 2(\bar{\sigma}_x^i - \sigma_t^x)^2(\bar{\sigma}_x^y - \sigma_t^y)^2 + 2(\sigma_t^x)^2(\bar{\sigma}_x^y - \sigma_t^y)^2,
\]
\[
(\bar{\sigma}_x^i \sigma_t^z - \sigma_t^x \sigma_t^z)^2 = (\bar{\sigma}_x^i - \sigma_t^x)(\bar{\sigma}_x^z + \sigma_t^z(\sigma_t^z - \sigma_t^x))^2 \leq 2(\bar{\sigma}_x^i - \sigma_t^x)^2(\bar{\sigma}_x^y)^2 + 2(\sigma_t^x)^2(\bar{\sigma}_x^y - \sigma_t^y)^2,
\]
then
\[
\mathbb{E} \left[ \left( \int_0^t \left( \psi(x(u)) - \psi(x(u)) \right) dW_i(u) \right)^2 \right] \leq C \mathbb{E} \left[ \int_0^t (\bar{\sigma}_x^i - \sigma_t^x)^2 + (\bar{\sigma}_y^i - \sigma_t^x)^2 + (\bar{\sigma}_z^i - \sigma_t^x)^2 ds \right]
\]

and $y, z$ coordinates of the second term in (36) are similar. Summing up $x, y, z$ coordinates, the second term in (36) is bounded by
\[
\sup_{1 \leq i \leq N, 0 \leq s \leq t} \mathbb{E} \left[ \left\| \int_0^t (\psi(x(u)) - \psi(x(u))) dW_i(u) \right\|^2 \right] \leq C_2 t \int_0^t e(s) ds.
\]

For the third term in (36)
\[
\left\| \int_0^t \mu_i(\sigma(s)) ds \right\|^2 \leq C_3 \delta t^2,
\]

since $\|\sigma_i\| = 1$ and $s - \frac{1}{\delta t} \leq \delta t$.

Apply Itô isometry again for the fourth term in (36),
\[
\mathbb{E} \left[ \left\| \int_0^t \psi_i(\sigma(s)) dW_i(u) \right\|^2 \right] \leq C_4 \delta t.
\]
From Cauchy inequality and \( \mathbb{E} \left[ \left\| \theta^j_i \right\|^2 \right] \leq C \varepsilon^6 \) in Proposition 3.3, the fifth term in (36) is bounded by

\[
\mathbb{E} \left[ \left\| \sum_{j=0}^{t - 1} \frac{1}{\sqrt{t}} \theta^j_i \right\|^2 \right] \leq \sqrt{\frac{t}{\delta t}} \sum_{j=0}^{t - 1} \mathbb{E} \left[ \left\| \theta^j_i \right\|^2 \right] \leq C_5 \left( \frac{t}{\delta t} \right)^2 \varepsilon^6 = C_6 \delta t.
\]

From Proposition 3.2, \( \mathbb{E} \left[ \phi^j_i \cdot \phi^k_i \right] \leq C \delta_{jk} \varepsilon^3 \) with \( \delta_{jk} \) the Kronecker delta, the sixth term in (36)

\[
\mathbb{E} \left[ \left\| \sum_{j=0}^{t - 1} \frac{1}{\sqrt{t}} \phi^j_i \right\|^2 \right] = \sum_{j=0}^{t - 1} \mathbb{E} \left[ \left\| \phi^j_i \right\|^2 \right] \leq C_7 \left( \frac{t}{\delta t} \right) \varepsilon^3 \leq C_8 \sqrt{\delta t}.
\]

Combining all above, we get the Grönwall inequality (34).

**Remark 3.4.** In Grönwall inequality, the \( C_3 \sqrt{\delta t} \) term decides the order of convergence. It comes from \( \mathbb{E} \left[ \left\| \sum_{j=0}^{t - 1} \frac{1}{\sqrt{t}} \phi^j_i \right\|^2 \right] \), which we show as \( O(\varepsilon^3) \) term in (36).

With Proposition 3.3, we can get a uniform bound by using Doob’s martingale inequality in (26) for a nonnegative submartingale \( X_t \) and constant \( p > 1 \):

\[
\mathbb{E} \left[ \sup_{0 \leq s \leq t} X_s \right]^{1/p} \leq \frac{p}{p - 1} \mathbb{E} \left[ \left\| X_t \right\|^{p} \right]^{1/p}.
\]

(37)

**Proposition 3.4.** Define the error between M-H and SDE dynamics for \( i \)-th spin as

\[
e_i(t) = \mathbb{E} \left[ \sup_{0 \leq s \leq t} \left\| \sigma_i(s) - \bar{\sigma}_i(s) \right\|^2 \right] \quad t \in [0, T], 1 \leq i \leq N,
\]

for any \( T \in \mathbb{R}^+ \). There exists some constant \( C \) as a function of \( T, N, J, \beta \) and independent of \( i, \delta t \)

\[
e_i(t) \leq C \sqrt{\delta t}.
\]

(39)

**Proof.** Similar to (36) in Proposition 3.3 we have

\[
\mathbb{E} \left[ \sup_{0 \leq s \leq t} \left\| \sigma_i - \bar{\sigma}_i \right\|^2 \right] \leq C \mathbb{E} \left[ \sup_{0 \leq s \leq t} \left( \int_0^{\sqrt{t} \delta t} \mu_i(\sigma) - \mu_i(\bar{\sigma}) \, du \right)^2 \right] + \mathbb{E} \left[ \sup_{0 \leq s \leq t} \left( \int_0^{\sqrt{t} \delta t} \mu_i(\bar{\sigma}) \, du \right)^2 \right] + \mathbb{E} \left[ \sup_{0 \leq s \leq t} \left( \int_0^{T} \phi^j_i \right)^2 \right]
\]

and each term on the RHS will be bounded by \( C \sqrt{\delta t} \) for some constant \( C \).

Applying Hölder’s inequality for the first term in (40):

\[
\mathbb{E} \left[ \sup_{0 \leq s \leq t} \left( \int_0^{\sqrt{t} \delta t} \mu_i(\sigma) - \mu_i(\bar{\sigma}) \, du \right)^2 \right] \leq \mathbb{E} \left[ \sup_{0 \leq s \leq t} t \int_0^{\sqrt{t} \delta t} \left\| \mu_i(\sigma) - \mu_i(\bar{\sigma}) \right\|^2 \, du \right] \leq \mathbb{E} \left[ t \int_0^{T} \left\| \mu_i(\sigma) - \mu_i(\bar{\sigma}) \right\|^2 \, du \right] \leq C t^2 \sum_{j=i-1}^{i+1} \mathbb{E} \left[ \left\| \sigma_i(s) - \bar{\sigma}_i(s) \right\|^2 \right] \leq C t^2 \sqrt{\delta t}.
\]
The last inequality is from \( \sup_{0 \leq s \leq t} \mathbb{E} \left[ \| \sigma_i(s) - \tilde{\sigma}_i(s) \|^2 \right] \leq C \sqrt{\delta t} \) in Proposition 3.3.

For the second term in (40), the length of integral is smaller than \( \delta t \) and \( \| \mu_i(\sigma) \| \leq C \) as \( \| \sigma \| = 1 \), so

\[
\sup_{0 \leq s \leq t} \left\| \int_{\left[ \frac{t}{\sqrt{\delta t}} \right]}^{s} \mu_i(\tilde{\sigma})du \right\|^2 \leq C \delta t^2. \tag{41}
\]

The integral in the third term of (40) is a martingale. For \( \zeta = x, y, z \), denote

\[
M_{t, \zeta} \equiv \left( \int_{0}^{\left[ \frac{\tilde{\sigma}}{\sqrt{\delta t}} \right]} \psi_i(\sigma) - \psi_i(\tilde{\sigma})dW_i - \int_{\left[ \frac{\tilde{\sigma}}{\sqrt{\delta t}} \right]}^{s} \psi_i(\tilde{\sigma}_i)dW_i \right)_{\zeta}.
\]

This is a Martingale and \( X_t = \| M_{t, \zeta} \| \) is a nonnegative submartingale, hence by Doob’s inequality \[37\]

\[
\mathbb{E} \left[ \| \sup_{0 \leq s \leq t} X_s \| \right] \leq 4 \mathbb{E} \left[ \| X_t \|^2 \right].
\]

For a nonnegative submartingale \( X_t \)

\[
\mathbb{E} \left[ \sup_{0 \leq s \leq t} X_s^2 \right] = \mathbb{E} \left[ \left( \sup_{0 \leq s \leq t} X_s \right)^2 \right] \leq C \mathbb{E} [ X_t^2 ] = C \mathbb{E} [ M_{t, \zeta}^2 ].
\]

Applying Itô isometry for the last term similar to the proof of Proposition 3.3 and summing for all coordinates \( \zeta = x, y, z \):

\[
\mathbb{E} \left[ \sup_{0 \leq s \leq t} \left\| \int_{0}^{\left[ \frac{\tilde{\sigma}}{\sqrt{\delta t}} \right]} \psi_i(\sigma) - \psi_i(\tilde{\sigma})dW_i - \int_{\left[ \frac{\tilde{\sigma}}{\sqrt{\delta t}} \right]}^{s} \psi_i(\tilde{\sigma}_i)dW_i \right\|^2 \right]
\leq C \mathbb{E} \left[ \left( \int_{0}^{\left[ \frac{\tilde{\sigma}}{\sqrt{\delta t}} \right]} \psi_i(\sigma) - \psi_i(\tilde{\sigma})dW_i - \int_{\left[ \frac{\tilde{\sigma}}{\sqrt{\delta t}} \right]}^{s} \psi_i(\tilde{\sigma}_i)dW_i \right)^2 \right]
\leq C_1 \mathbb{E} \left[ \int_{0}^{\left[ \frac{\tilde{\sigma}}{\sqrt{\delta t}} \right]} \| \sigma - \tilde{\sigma} \|^2 du \right] + C_2 \mathbb{E} \left[ \int_{\left[ \frac{\tilde{\sigma}}{\sqrt{\delta t}} \right]}^{s} \| \sigma \|^2 du \right]
\leq C_1 \sqrt{\delta t} + C_2 \delta t.
\]

From Cauchy inequality, the fourth term in (40)

\[
\sup_{0 \leq s \leq t} \left( \sum_{j=0}^{\left[ \frac{t}{\sqrt{\delta t}} \right]} \theta_i^j \right)^2 \leq \sup_{0 \leq s \leq t} \left( \sum_{j=0}^{\left[ \frac{s}{\sqrt{\delta t}} \right]} \theta_i^j \right)^2 \leq \left( \frac{t}{\delta t} \right) \sum_{j=0}^{\left[ \frac{t}{\sqrt{\delta t}} \right]} \| \theta_i^j \|^2,
\]

from \[3.1\] \( \mathbb{E} \left[ \| \theta_i^j \|^2 \right] \leq C \varepsilon^6 \) so the last expectation is bounded by \( C \delta t \).

In the fifth term of (40), \( \sum_{j=0}^{\left[ \frac{t}{\sqrt{\delta t}} \right]} \phi_i^j \) is a discrete martingale. Again using martingale inequality for each coordinate and then summing up,

\[
\mathbb{E} \left[ \sup_{0 \leq s \leq t} \left\| \sum_{j=1}^{\left[ \frac{t}{\delta t} \right]} \phi_i^j \right\|^2 \right] \leq \mathbb{E} \left[ \left( \sum_{j=1}^{\left[ \frac{t}{\delta t} \right]} \phi_i^j \right)^2 \right], \tag{42}
\]

from \[3.2\] \( \mathbb{E} \left[ \phi_i^j \cdot \phi_i^k \right] \leq \delta_{jk} C \varepsilon^3 \), it is bounded by

\[
\mathbb{E} \left[ \sum_{j=1}^{\left[ \frac{t}{\delta t} \right]} \| \phi_i^j \|^2 \right] \leq C \left( \frac{t}{\delta t} \right) \varepsilon^3 \leq C \sqrt{\delta t}. \tag{43}
\]

Combining above, (39) is obtained.
4 From SDE system to deterministic PDE

In this section, we explain the convergence from the SDE system (14) to the deterministic Landau-Lifshitz equation without dispersion term (15) with proper choice of \( \beta = N^\gamma \) and number of particles \( N \to \infty \).

**Remark 4.1.** For the XY model from \( T^1 \to S^1 \), the convergence from Langevin equation (8) to harmonic map heat flow equation (11) can be shown similarly by taking \( P^\dagger_\sigma \) \((y) = y - (x,y)x \) and the rest of the proof stays the same.

From [10], for sufficiently regular initial data, there exists a global smooth solution to the Landau-Lifshitz equation with periodic boundary conditions. We will assume such a solution exists in all contexts below. Since the finite difference approximation (18) will converge to the Landau-Lifshitz equation (5) as \( N \to \infty \), we only need to compare the SDE system (14) and the ODE system (15).

In the following the error between (14) and (15) is calculated. Since \( \beta = N^\gamma, \gamma > 1 \) and \( N \to \infty \), we denote

\[
\epsilon = \sqrt{\frac{N}{\beta}}
\]

(44)
as a small parameter going to zero with \( N \to \infty \). The SDE is then written as

\[
d\sigma_i = P^\dagger_\sigma (\Delta N \sigma_i) \, dt - e^2 \sigma_i \, dt - eP^\dagger_\sigma (dW_i).
\]

(45)

**Lemma 4.1.** Define the error between SDE (14) and ODE (15) for i-th spin as \( \tilde{e}_i \equiv \sigma_i - \tilde{\sigma}_i \) and define \( e_i \equiv e^{-p} \tilde{e}_i \) for \( 0 < p < 1 \). Define

\[
e = \frac{1}{N} \sum_i \|e_i\|^2,
\]

(46)
we have the following inequality

\[
e(t) \leq \int_0^t \left( C_1 \epsilon^{3/2} + C_2 \epsilon \right) \, ds + C_3 \epsilon^{2-2p} t + \int_0^t \epsilon^{1-p} \frac{1}{N} \sum_i \left( P^\dagger_\sigma_i (dW_i(t), e_i) \right),
\]

(47)
with \( \epsilon \) small enough so that \( \epsilon^p N^{5/2} \leq 1 \).

**Proof.** Taking the projection given by

\[
P^\dagger_\sigma (\Delta \sigma_i) = -\sigma_i \times (\sigma_i \times \Delta \sigma_i) = \Delta \sigma_i - (\Delta \sigma_i, \sigma_i) \sigma_i
\]
together with \( \|\sigma_i\| = 1 \), we have that

\[
(\Delta N \sigma_i, \sigma_i) = -\frac{1}{2} (\|\nabla^+_N \sigma_i\|^2 + \|\nabla^-_N \sigma_i\|^2),
\]
where \( \nabla^+_N \sigma_i = N(\sigma_{i+1} - \sigma_i), \nabla^-_N \sigma_i = N(\sigma_i - \sigma_{i-1}) \). The SDE system (14) can then be written as

\[
d\sigma_i = \left( \Delta N \sigma_i + \frac{1}{2} (\|\nabla^+_N \sigma_i\|^2 + \|\nabla^-_N \sigma_i\|^2) \sigma_i \right) \, dt - e^2 \sigma_i \, dt - eP^\dagger_\sigma (dW_i)
\]
and the ODE system (15) can similarly be written as

\[
d\tilde{\sigma}_i = \left( \Delta N \tilde{\sigma}_i + \frac{1}{2} (\|\nabla^+_N \tilde{\sigma}_i\|^2 + \|\nabla^-_N \tilde{\sigma}_i\|^2) \tilde{\sigma}_i \right) \, dt.
\]

By definition \( \tilde{e}_i = \sigma_i - \tilde{\sigma}_i \) satisfies the following equation

\[
d\tilde{e}_i = \Delta N \tilde{e}_i \, dt + \frac{1}{2} \left[ 2(\nabla^+_N \tilde{\sigma}_i, \nabla^+_N \tilde{e}_i) \sigma_i + \|\nabla^+_N \tilde{e}_i\|^2 \sigma_i + 2(\nabla^-_N \tilde{\sigma}_i, \nabla^-_N \tilde{e}_i) \sigma_i + \|\nabla^-_N \tilde{e}_i\|^2 \sigma_i \right] \, dt
\]
\[
+ \frac{1}{2} \left( \|\nabla^+_N \tilde{\sigma}_i\|^2 + \|\nabla^-_N \tilde{\sigma}_i\|^2 \right) \tilde{e}_i \, dt - e^2 \sigma_i \, dt + eP^\dagger_\sigma (dW_i(t)).
\]
Since $\tilde{e}_i = e^p e_i$ with $0 < p < 1$,

$$\begin{align*}
\mathrm{d}e_i = & \Delta_N e_i \mathrm{d}t + \frac{1}{2} \left[ 2(\nabla_N^+ \tilde{\sigma}_i, \nabla_N^+ e_i) \sigma_i + e^p \| \nabla_N^+ e_i \|^2 \sigma_i + 2(\nabla_N^- \tilde{\sigma}_i, \nabla_N^- e_i) \sigma_i + e^p \| \nabla_N^- e_i \|^2 \sigma_i \right] \mathrm{d}t \\
& + \frac{1}{2} \left( \| \nabla_N^+ \tilde{\sigma}_i \|^2 + \| \nabla_N^- \tilde{\sigma}_i \|^2 \right) e_i \mathrm{d}t - e^{-p} \sigma_i \mathrm{d}t + e^{1-p} P_{\sigma_i}^\perp (\mathrm{d}W_i(t)).
\end{align*}$$

(48)

Applying Itô’s formula to $\frac{1}{2} \| e_i \|^2$, we have that

$$\begin{align*}
\frac{1}{2} \| e_i \|^2 &= (e_i, \Delta_N e_i) + I_i \\
&= (\Delta_N e_i, e_i) + \frac{1}{2} \left[ 2(\nabla_N^+ \tilde{\sigma}_i, \nabla_N^+ e_i) + e^p \| \nabla_N^+ e_i \|^2 + 2(\nabla_N^- \tilde{\sigma}_i, \nabla_N^- e_i) + e^p \| \nabla_N^- e_i \|^2 \right] \sigma_i \mathrm{d}t \\
&+ \frac{1}{2} \left( \| \nabla_N^+ \tilde{\sigma}_i \|^2 + \| \nabla_N^- \tilde{\sigma}_i \|^2 \right) \| e_i \|^2 \mathrm{d}t - e^{-p} \sigma_i \mathrm{d}t + e^{1-p} \left( P_{\sigma_i}^\perp (\mathrm{d}W_i(t), e_i) \right) + I_i,
\end{align*}$$

where $I_i$ represents the Itô correction term of order $O(\epsilon^2 - 2p)$ as shown in the following computation.

To calculate the Itô correction $I_i$, we consider an SDE system for both $e_i$ in (18) and $\sigma_i$ in (14). The Itô correction $I_i$ for $\| e_i \|^2$ combines three parts corresponding to $\frac{\partial^2 e_i^2}{\partial \sigma_i^2}, \frac{\partial^2 e_i^2}{\partial \sigma_i \partial e_i}$, and $\frac{\partial^2 e_i^2}{\partial e_i^2}$. Since $\| \sigma_i \|= 1$ we take

$$\| P_{\sigma_i}^\perp (\mathrm{d}W_i(t)) \|^2$$

as bounded by $C \| \sigma_i \| \mathrm{d}t$. The first term, $\frac{\partial^2 e_i^2}{\partial \sigma_i^2}$, is a constant and $\| e^{-p} P_{\sigma_i}^\perp (\mathrm{d}W_i(t)) \|^2 \leq C \epsilon^2 - 2p \epsilon \mathrm{d}t$.

The second term, $\frac{\partial^2 e_i^2}{\partial \sigma_i \partial e_i} = \frac{\partial^2 e_i^2}{\partial \sigma_i \partial e_i}(\sigma_i, e_i)$, is order $\epsilon^{-p}$ but $e^{-p} P_{\sigma_i}^\perp (\mathrm{d}W_i(t)) \cdot e^{1-p} P_{\sigma_i}^\perp (\mathrm{d}W_i(t))$ is order $\epsilon^2 - 2p \epsilon \mathrm{d}t$ so the Itô correction for the second term is also $O(\epsilon^2 - 2p \epsilon \mathrm{d}t)$. For the third term $\frac{\partial^2 e_i^2}{\partial e_i^2} = \epsilon^{-2p} \frac{\partial^2 (\sigma_i - \tilde{\sigma}_i)}{\partial e_i^2}$ but

$$\| e P_{\sigma_i}^\perp (\mathrm{d}W_i(t)) \|^2 \leq C \epsilon^2 \epsilon \mathrm{d}t$$

so the Itô correction for the third term is also $O(\epsilon^2 - 2p \epsilon \mathrm{d}t)$.

From periodic boundary condition, we know that

$$\sum_{i=1}^{N} (\Delta_N e_i, e_i) = - \sum_{i} \| \nabla_N^+ e_i \|^2 - \sum_{i} \| \nabla_N^- e_i \|^2,$$

hence summing up $\| e_i \|^2$ we have that

$$\begin{align*}
\mathrm{d} \left( \sum_i \| e_i \|^2 \right) &= - \sum_i \left( \| \nabla_N^+ e_i \|^2 + \| \nabla_N^- e_i \|^2 \right) \mathrm{d}t + \sum_i \left[ 2(\nabla_N^+ \tilde{\sigma}_i, \nabla_N^+ e_i) + e^p \| \nabla_N^+ e_i \|^2 + 2(\nabla_N^- \tilde{\sigma}_i, \nabla_N^- e_i) + e^p \| \nabla_N^- e_i \|^2 \right] \sigma_i \mathrm{d}t \\
&+ \sum_i \left( \| \nabla_N^+ \tilde{\sigma}_i \|^2 + \| \nabla_N^- \tilde{\sigma}_i \|^2 \right) \| e_i \|^2 \mathrm{d}t - 2N \epsilon^2 - p \sigma_i \mathrm{d}t + 2 \sum_i \epsilon^1 - p \left( P_{\sigma_i}^\perp (\mathrm{d}W_i(t), e_i) \right) + 2 \sum_i I_i \\
\leq & - \sum_i \left( \| \nabla_N^+ e_i \|^2 + \| \nabla_N^- e_i \|^2 \right) \mathrm{d}t + \sum_i \left[ 2(\nabla_N^+ \tilde{\sigma}_i, \nabla_N^+ e_i) + e^p \| \nabla_N^+ e_i \|^2 + 2(\nabla_N^- \tilde{\sigma}_i, \nabla_N^- e_i) + e^p \| \nabla_N^- e_i \|^2 \right] \sigma_i \mathrm{d}t \\
&+ \sum_i \left( \| \nabla_N^+ \tilde{\sigma}_i \|^2 + \| \nabla_N^- \tilde{\sigma}_i \|^2 \right) \| e_i \|^2 \mathrm{d}t - 2N \epsilon^2 - p \sigma_i \mathrm{d}t + 2 \sum_i \epsilon^1 - p \left( P_{\sigma_i}^\perp (\mathrm{d}W_i(t), e_i) \right) + N \epsilon^2 - 2p \mathrm{d}t
\end{align*}$$

(49)

For the second term of (49), from the Cauchy-Schwarz inequality, we observe that

$$\begin{align*}
| (\nabla_N^+ \tilde{\sigma}_i, \nabla_N^+ e_i) (\sigma_i, e_i) | & \leq \frac{1}{2} \left( \| \nabla_N^+ \tilde{\sigma}_i \|^2 + \| \nabla_N^+ e_i \|^2 \right), \\
| (\nabla_N^- \tilde{\sigma}_i, \nabla_N^- e_i) (\sigma_i, e_i) | & \leq \frac{1}{2} \left( \| \nabla_N^- \tilde{\sigma}_i \|^2 + \| \nabla_N^- e_i \|^2 \right).
\end{align*}$$

Since the solution for Landau-Lifshitz equation is smooth, in the third term of (49), $\| \nabla_N^+ \tilde{\sigma}_i \|^2 + \| \nabla_N^- \tilde{\sigma}_i \|^2$ can be bounded by some constant $C$. For the fourth term in (49), $| \epsilon^2 - p (\sigma_i, e_i) | = | \epsilon^2 - 2p (\sigma_i, e^p e_i) | \leq \epsilon^2 - 2p$.
since $\epsilon e_i = \sigma_i - \tilde{\sigma}_i$. Hence from \cite{49},

$$\sum_i \|e_i\|^2 \leq \int_0^t \epsilon^p \sum_i \left(\|\nabla_N^+ e_i\|^2 + \|\nabla_N e_i\|^2\right) \|e_i\| ds + C_1 \int_0^t \sum_i \|e_i\|^2 ds + C_2 N \epsilon^{2-2p} t + \int_0^t \epsilon^{1-p} \sum_i \left(P_{\sigma_i}^\perp (dW_i(t), e_i)\right).$$

Using the assumption that $\epsilon N^{5/2} \leq 1$ we bound the $\sum_i \left(\epsilon^p \|\nabla_N^+ e_i\|^2 + \epsilon^p \|\nabla_N e_i\|^2\right) \|e_i\|$ term by $C \sum_i \frac{1}{N} \|e_i\|^3$. Hence,

$$\frac{1}{N} \sum_i \left(\epsilon^p \|\nabla_N^+ e_i\|^2 + \epsilon^p \|\nabla_N e_i\|^2\right) \|e_i\| \leq C \frac{1}{N} \sum_i \|e_i\|^3 \leq C \left(\frac{1}{N} \sum_i \|e_i\|^2\right)^{\frac{2}{3}}$$

as the $p$-norm is decreasing.

As $e = \frac{1}{N} \sum_i \|e_i\|^2$, we arrive at \cite{47}.

\[\square\]

**Remark 4.2.** If we choose the parameters such that the small Itô correction term from martingale $CN \epsilon^{2-2p}$ is lower order in $N$ and $\epsilon N^5 \sim O(1)$, we could show a similar result for $e = \sum_i \|e_i\|^2$ instead of $e = \frac{1}{N} \sum_i \|e_i\|^2$. And this way we could bound $\mathbb{E}_n \left[\sum_i \|e_i\|^2\right]$.

Intuitively the inequality from Lemma 4.1 is of Grönwall type and the martingale part,

$$2 \int_0^t \epsilon^{1-p} \frac{1}{N} \sum_i \left(P_{\sigma_i}^\perp (dW_i(t), e_i)\right)$$

has small coefficient $\epsilon^{1-p}$. This means with large probability

$$e(t) \leq \int_0^t \left(C_1 \epsilon^{3/2} + C_2 \epsilon\right) ds + C_3 \epsilon^{2-2p} t + \text{small term from martingale}$$

and $e(t)$ is bounded for a long time interval. We use this idea to show the following proposition.

**Proposition 4.1.**

$$\mathbb{P} \left(e(t) \leq \epsilon^{2-2p} \exp(Ct)\right) \geq 1 - e^{-\frac{N}{\epsilon}} \quad \forall \ t \in [0, T]$$

for some constant $C$ and $T$ satisfying $\epsilon^{1-p} e^{\frac{1}{2} + CT} \leq 1$.

To prove Proposition 4.1 we will use the exponential martingale inequality for continuous $L^2$ martingale $M_t$ as in \cite{12} p. 25) or \cite{2} :

$$\mathbb{P}(\sup_t (M_t - a/2\langle M\rangle_t) > b) \leq e^{-ab}$$

where $\langle M\rangle_t$ is the quadratic variation for $M_t$.

For the martingale in \cite{49}, we calculate its quadratic variation in the following lemma.

**Lemma 4.2.** The quadratic variation for the martingale $M_t = 2 \int_0^t \epsilon^{1-p} \frac{1}{N} \sum_i \left(P_{\sigma_i}^\perp (dW_i(t), e_i)\right)$ is

$$\langle M\rangle_t = 4 \int_0^t \frac{\epsilon^{2-2p}}{N^2} \sum_i \|e_i\|^2 - \langle \sigma_i, e_i\rangle^2 \, ds.$$  

**Proof.** The quadratic variation for $M_t$ is captured by a direct summation of the square of the coefficients of

\[\square\]
the white noise, namely

\[
\left\langle 2 \int_0^t e^{1-p} \frac{1}{N} \sum_i \left( P_{\sigma_i}^\perp dW_i(t), e_i \right) \right\rangle_t = \frac{4e^{2-2p}}{N^2} \left\langle \int_0^t \sum_i \left( P_{\sigma_i}^\perp dW_i(t), e_i \right) \right\rangle_t
\]

\[
= \frac{4e^{2-2p}}{N^2} \int_0^t \sum_i \left( e_i - (\sigma_i, e_i) \sigma_i \right) \left( e_i - (\sigma_i, e_i) \sigma_i \right) dt = \frac{4e^{2-2p}}{N^2} \int_0^t \sum_i \left( e_i^2 + (\sigma_i, e_i)^2 (\sigma_i)^2 - 2e_i \sigma_i (\sigma_i, e_i) dt
\]

\[
= \frac{4e^{2-2p}}{N^2} \int_0^t \sum_i \|e_i\|^2 - (\sigma_i, e_i)^2 dt.
\]

Now taking \( a = \frac{1}{N^2} \) and \( b = e^{2-2p} \) in the inequality (52), we have that

\[
\mathbb{P} \left( \sup_{0 \leq s \leq t} \left( 2 \int_0^s e^{1-p} \frac{1}{N} \sum_i \left( P_{\sigma_i}^\perp dW_i(t), e_i \right) \right) du - \int_0^s \frac{1}{N} \sum_i \left( \|e_i\|^2 - (\sigma_i, e_i)^2 \right) du \right) > e^{2-2p} \leq e^{-N/2}.
\]

Thus, for probability \( P \geq 1 - e^{-N/2} \),

\[
2 \int_0^t e^{1-p} \frac{1}{N} \sum_i \left( P_{\sigma_i}^\perp dW_i(t), e_i \right) - \int_0^t \frac{1}{N} \sum_i \left( \|e_i\|^2 - (\sigma_i, e_i)^2 \right) ds 
\]

\[
\leq \sup_{0 \leq s \leq t} \left( 2 \int_0^s e^{1-p} \frac{1}{N} \sum_i \left( P_{\sigma_i}^\perp dW_i(t), e_i \right) \right) du - \int_0^s \frac{1}{N} \sum_i \left( \|e_i\|^2 - (\sigma_i, e_i)^2 \right) du
\]

\[
\leq e^{2-2p}.
\]

Combining this with (57), we observe

\[
e(t) \leq \int_0^t \left( C_1 e^{3/2} + C_2 e \right) ds + C_3 e^{2-2p} t + 2 \int_0^t e^{1-p} \frac{1}{N} \sum_i \left( P_{\sigma_i}^\perp dW_i(t), e_i \right)
\]

\[
\leq \int_0^t \left( C_1 e^{3/2} + C_2 e \right) ds + C_3 e^{2-2p} t + \int_0^t \frac{1}{N} \sum_i \left( \|e_i\|^2 - (\sigma_i, e_i)^2 \right) ds + e^{2-2p}
\]

\[
\leq \int_0^t \left( C_1 e^{3/2} + (C_2 + 1) e \right) ds + C_3 e^{2-2p} t + e^{2-2p}
\]

using the definition of \( e(t) \) and \( (\sigma_i, e_i)^2 \leq \|e_i\|^2 \).

Since (55) is a Grönwall type inequality, we build a special upper solution \( u = e^{2-2p} e^{(C_1+C_2+C_3+1)t} \). Then

\[
du = (C_1 + C_2 + C_3 + 1)u \geq C_1 u^{3/2} + (C_2 + 1)u + C_3 e^{2-2p},
\]

where \( C_1 u \geq C_1 u^{3/2} \) when \( e^{1-p} e^{(C_1+C_2+C_3+2)t} \leq 1 \). We observe that

\[
e^{(C_1+C_2+C_3+1)t} \geq 1 + (C_1 + C_2 + C_3 + 1)t,
\]

so \( C_3 u \geq C_3 e^{2-2p} \). As \( u(0) = e^{2-2p} \), we have that

\[
u(t) \geq \int_0^t \left( C_1 u^{3/2} + (C_2 + 1)u \right) ds + C_3 e^{2-2p} t + e^{2-2p}
\]

(56)
and \( u(t) \) is an upper bound for \( e(t) \).

When \( \epsilon \) is small enough we have that \( \epsilon^{1-p}e^{\frac{1}{2}(C_1+C_2+C_3+2T)} \leq 1 \) and \( u(t) \) is an upper bound for \( e(t) \). We observe

\[
P(e(t) \leq u(t) = \epsilon^{2-p}e^{\frac{1}{2}(C_1+C_2+C_3+1)t}) \geq 1 - \epsilon^{-N/2}, \quad t \in [0, T].
\]

In fact, as \( e_i = \epsilon^{-p}(\sigma_i - \bar{\sigma}_i) \), the bound \( e(t) = \frac{1}{N} \sum_{i} \|e_i\|^2 \leq C \) by some constant \( C \) is sufficient. Appealing to a stopping time argument similar to the strong uniqueness proof of the SDE with locally Lipschitz continuous coefficients (see e.g. [16], Chapter 5.2, Theorem 2.5), we have the following result.

**Proposition 4.2.** Given \( \epsilon, N > 0 \), there exists a constant \( C \) independent of \( \epsilon, N \) such that if \( \epsilon^{2-2p}Te^{Ct} \leq 1 \), then

\[
\mathbb{E}[e(t)] \leq 1, \quad t \in [0, T].
\]

**Proof.** Define a deterministic time \( T \equiv \min\{t \in [0, \infty) : \mathbb{E}[e(t)] \geq 1\} \) and a stopping time \( \tau \equiv \min\{t \in [0, T] : e(t) \geq 1\} \). Since \( e(0) = 0 \), we have both \( T > 0 \) and \( \tau > 0 \). If \( T \) is infinite then we are done, so assume \( T \) is bounded.

From Lemma 4.1,

\[
e(t \wedge \tau) \leq \epsilon^{2-2p}(t \wedge \tau) + \int_0^{t \wedge \tau} C_1 \epsilon^{3/2}(s) + C_2 e(s) ds + \int_0^{t \wedge \tau} \epsilon^{1-p} \frac{1}{N} \sum_i \mathbb{P}_{\sigma_i}^- (dW_i).
\]

As \( \epsilon \geq 0 \), we have

\[
e(t \wedge \tau) \leq \epsilon^{2-2p}(t \wedge \tau) + \int_0^t C_1 \epsilon^{3/2}(s \wedge \tau) + C_2 e(s \wedge \tau) ds + \int_0^{t \wedge \tau} \epsilon^{1-p} \frac{1}{N} \sum_i \mathbb{P}_{\sigma_i}^- (dW_i),
\]

and \( \epsilon^{3/2}(s \wedge \tau) \leq e(s \wedge \tau) \) as \( e(s \wedge \tau) \leq 1 \), so

\[
e(t \wedge \tau) \leq \epsilon^{2-2p}(t \wedge \tau) + \int_0^t (C_1 + C_2) e(s \wedge \tau) ds + \int_0^{t \wedge \tau} \epsilon^{1-p} \frac{1}{N} \sum_i \mathbb{P}_{\sigma_i}^- (dW_i).
\]

Taking the expectation on both sides,

\[
\mathbb{E}[e(t \wedge \tau)] \leq \epsilon^{2-2p} \mathbb{E}[e(t \wedge \tau)] + \int_0^t (C_1 + C_2) \mathbb{E}[e(s \wedge \tau)] ds.
\]

The expectation \( \mathbb{E}\left[ \int_0^{t \wedge \tau} \mathbb{P}_{\sigma_i}^- (dW_i) \right] = 0 \) can be deduced from optional stopping theorem for continuous time or take \( \int_0^{t \wedge \tau} \mathbb{P}_{\sigma_i}^- (dW_i) = \int_0^T \mathbb{1}(s < t \land \tau) \mathbb{P}_{\sigma_i}^- (dW_i(s)) \). Notice \( \mathbb{E}[(t \wedge \tau)] \leq T \), so

\[
\mathbb{E}[e(t \wedge \tau)] \leq \int_0^t (C_1 + C_2) \mathbb{E}[e(s \wedge \tau)] ds + \epsilon^{2-2p} T e^{(C_1 + C_2)t}.
\]

Choosing \( C > C_1 + C_2 \), the result follows.

By similar arguments, a uniform bound on \( e(t) \) can be obtained with a weaker condition on \( T \).

**Proposition 4.3.** Given \( \epsilon, N > 0 \), there exist constants \( \tilde{C}_1, \tilde{C}_2 \) independent of \( \epsilon, N \) such that if \( (\epsilon^{2-2p}T + \tilde{C}_1 \epsilon^{\frac{2-2p}{N}}) e^{C_3 t} \leq 1 \), then

\[
\mathbb{E}\left[ \sup_{0 \leq s \leq t} e(s) \right] \leq 1, \quad t \in [0, T].
\]
Proof. Define $T \equiv \min\{t : \mathbb{E}[\sup_{0 \leq s \leq t} e(s)] \geq 1\}$ and $\tau \equiv \min\{t \in [0, T] : e(t) \geq 1\}$. Since $e(0) = 0$ we still have $T > 0, \tau > 0$.

Again from Lemma 4.1 we observe

$$e(t \wedge \tau) \leq \int_0^t C_1 e^{3/2}(s \wedge \tau) + C_2 e(s \wedge \tau) ds + e^{2-2p}(t \wedge \tau) + \int_0^{t \wedge \tau} e^{1-\frac{1}{N}} \sum_i \left( \mathbb{P}_{\sigma_i}^+ (dW_i), e_i \right).$$

(63)

Taking the supremum on both sides,

$$\sup_{0 \leq s \leq t} e(s \wedge \tau) \leq \sup_{0 \leq s \leq t} \int_0^s C_1 e^{3/2}(u \wedge \tau)
+ C_2 e(u \wedge \tau) du + \sup_{0 \leq s \leq t} e^{2-2p}(s \wedge \tau) + \sup_{0 \leq s \leq t} \int_0^{s \wedge \tau} e^{1-\frac{1}{N}} \sum_i \left( \mathbb{P}_{\sigma_i}^+ (dW_i), e_i \right)(u).$$

(64)

and $0 \leq e(t \wedge \tau) \leq 1$ and $t \wedge \tau \leq T$ gives

$$\sup_{0 \leq s \leq t} e(s \wedge \tau) \leq \int_0^t (C_1 + C_2) e(u \wedge \tau) du + e^{2-2p}T + \sup_{0 \leq s \leq t} \int_0^{s \wedge \tau} e^{1-\frac{1}{N}} \sum_i \left( \mathbb{P}_{\sigma_i}^+ (dW_i), e_i \right)(u).$$

(65)

Taking expectations on both sides

$$\mathbb{E} \left[ \sup_{0 \leq s \leq t} e(s \wedge \tau) \right] \leq \int_0^t (C_1 + C_2) \mathbb{E} [e(u \wedge \tau)] du
+ e^{2-2p}T + \mathbb{E} \left[ \sup_{0 \leq s \leq t} \int_0^{s \wedge \tau} e^{1-\frac{1}{N}} \sum_i \left( \mathbb{P}_{\sigma_i}^+ (dW_i), e_i \right)(u) \right].$$

(66)

The first integral on the right hand side $\int_0^t (C_1 + C_2) \mathbb{E} [e(u \wedge \tau)] du \leq \int_0^t (C_1 + C_2) \mathbb{E} \left[ \sup_{0 \leq s \leq u} e(s \wedge \tau) \right] du$.

Doob’s Martingale inequality [17] is used to give a bound of $Ce^{1-2p}$ for the last expectation in (65).

Denote

$$M_s = \int_0^{s \wedge \tau} e^{1-\frac{1}{N}} \sum_i \left( \mathbb{P}_{\sigma_i}^+ (dW_i), e_i \right) = \int_0^s 1(u \leq \tau) e^{1-\frac{1}{N}} \sum_i \left( \mathbb{P}_{\sigma_i}^+ (dW_i), e_i \right)(u),$$

(67)

since $1(u \leq \tau) \in \mathcal{F}_u$ it is a martingale. Using Doob’s martingale inequality [17]

$$\mathbb{E} \left[ \left( \sup_{0 \leq s \leq t} M_s \right)^2 \right] \leq 4\mathbb{E} [M_t^2] = 4 \int_0^t \mathbb{E} \left[ e^{2-2p} \sum_i \|e_i\|^2 - (\sigma_i, e_i)^2 du \right] \leq C e^{2-4p}.$$

(68)

The second equality is from Itô isometry and the third inequality is because $\|\sigma_i\|, \|\tilde{\sigma}_i\| = 1$ so $|\langle \sigma_i, e_i \rangle| \leq \|\sigma_i\|$ and $\|e^p e_i\| = \|\sigma_i - \tilde{\sigma}_i\| \leq 2$.

Now a Grönwall’s inequality gives

$$\mathbb{E} \left[ \sup_{0 \leq s \leq t} e(s \wedge \tau) \right] \leq \int_0^t (C_1 + C_2) \mathbb{E} \left[ \sup_{0 \leq s \leq t} e(s \wedge \tau) \right] du + e^{2-2p}T + C_3 e^{2-4p}$$

(69)

and $\mathbb{E} \left[ \sup_{0 \leq s \leq t} e(s \wedge \tau) \right] \leq \left( e^{2-2p}T + C_3 e^{2-4p} \right) e^{(C_1 + C_2)t}$. As in the proof of the previous Proposition, choosing $C_2 > C_1 + C_2$ and $\tilde{C}_1 = C_3$, the result thus follows similarly.

$$\Box$$

5 Numerical results

In this section, we support our convergence results using numerical simulations of the systems, showing both the temporal dynamics and the order of convergence. The convergence tests indicate that the error decays
at least as well as predicted in Theorems 2.1 and 2.2. We check both the cases of the XY model and the classical Heisenberg model. The dynamics of the M-H algorithm are simulated as explained in Sec. 2.1. To simulate the SDE (14), written in the Itô sense, we use the stochastic Euler’s method combined with a normalizing step to project the spin back onto the sphere after each time step for both the XY model and the classical Heisenberg model. The PDE is numerically integrated by discretizing in space and using the Euler’s method presented in [29] which includes a normalization step.

The out-of-equilibrium to equilibrium dynamics of the M-H algorithm, SDE, and discretized PDE are shown in Figure 1. Figure 1a shows the $T^1 \rightarrow S^1$ case of the XY model in terms of the polar coordinate $\theta$ of each spin. Figure 1b shows the $T^1 \rightarrow S^2$ case of the classical Heisenberg model with each spin plotted on the same unit sphere; nearest neighbors are connected by a solid line. In both cases, the M-H dynamics tend to lag behind the SDE and PDE which more closely follow each other. This suggests the error between the M-H algorithm and the PDE is dominated by the error between the M-H algorithm and the SDE. Thus the order of convergence between M-H algorithm and Landau-Lifshitz equation should almost follow the order of convergence in Theorem 2.1.

Figure 1: Dynamics of M-H algorithm (red circles), Langevin equation (black stars) and Landau-Lifshitz equation (cyan diamonds) at various instances of time. They follow each other to converge to equilibrium. In both panels: lattice length $L = 2$, space discretization $\delta x = \frac{1}{N} = \frac{1}{10}$, time step size for M-H algorithm $\delta t = \frac{1}{N^3} = 0.001$, inverse temperature $\beta = N^{3/2} \approx 31.6$, proposal size $\varepsilon = \sqrt{\frac{N\beta}{\delta t}} \approx 0.0178$.

Figures 2 and 3 show the order of convergence for the error between the M-H algorithm and the Langevin equation with respect to the time step size $\delta t$, for which the equivalent M-H proposal size is $\varepsilon^2 = \delta t \frac{N}{\beta}$. The
error is calculated at a fixed time $T$ as

$$\mathbb{E} \left[ \frac{1}{N} \sum_{i=1}^{N} \left( \sigma_{\text{MH}}^i(T) - \sigma_{\text{SDE}}^i(T) \right)^2 \right]$$

(70)

where the expectation is taken over multiple realizations. All four frames support that the convergence is at least as good as $\delta t^{1/4}$, which is equivalent to the $\sqrt{\delta t}$ convergence given in theorem 2.1 since the 2-norm is used in the numerical experiments (thus the error is expected to be of order $(\sqrt{\delta t})^{1/2} = \delta t^{1/4}$). The faster convergence of order $\delta t^{1/2}$ in panels (b) and (c) of Fig. 3 we suspect is due to the fact that these out-of-equilibrium dynamics are dominated by the deterministic part of the SDE, and this part has different error scaling from the noisy dynamics. In equilibrium, the deterministic term, $P_\sigma^\perp(\delta_N \sigma_i)$, is small since it is zero at the minimum of the Hamiltonian (maximum of the Gibbs distribution), and the noisy part of the dynamics dominate.

Proposition 3.1 states the error on the deterministic drift of one Metropolis step, $\theta^\alpha$, is of size $\epsilon^3$. Dividing by a time-step $\delta t$ that is proportional to $\epsilon^2$ so that the left-hand side approximates a derivative for the SDE, the resulting error is $O(\epsilon)$ or equivalently $O(\delta t^{1/2})$ as seen in the numerical simulations. Similarly, from Proposition 3.2, the error on the stochastic diffusion of one Metropolis step, $\phi^\alpha$, is of size $\epsilon^{3/2}$ implying error of order $O(\delta t^{1/4})$, after dividing by the size of the first order term, $\epsilon$. To further test if the difference in convergence order is from the deterministic terms dominating, we increase the size of the noise, $\sqrt{\frac{N}{\beta}}$, in equation (13) by decreasing $\beta$ to make the noisy dynamics dominate. The out-of-equilibrium error with small $\beta = 1$ shown in Fig. 3 has $\delta t^{1/4}$ convergence, confirming the original statement of Theorem 2.1. We therefore conclude that the error bound of $\delta t^{1/4}$ is tight, and this error comes from the noisy part of the dynamics.

Figure 4 shows the error test for the difference between the M-H and the PDE dynamics with respect to $\delta x = \frac{1}{N}$. The discrete version of the PDE is simulated with the time-step scaling of $\delta t = \frac{1}{N^2}$ and $\beta = N^{3/2}$, which are also used with $\epsilon = \sqrt{\frac{N\delta t}{\beta}}$ in the M-H algorithm. These scalings give the order of convergence to be approximately 1, better than our analytical result in Theorem 2.2. A possible explanation is that the error from Theorem 2.1 dominates. As discussed above, Fig. 4 implies the error between the M-H algorithm and the Langevin SDE dominates over the error between the Langevin SDE and the Landau-Lifshitz equation, thus we would expect error of $\delta t^{1/2}$ in theorem 2.1 to dominate. Since we choose the scaling of $\delta t = \frac{1}{N^2} = \delta x^4$, this order of convergence with respect to $\delta x = \frac{1}{N}$ is expected to be $\delta t^{1/4} = \delta x$, or order one. We also point out that the scalings of $\delta t = \frac{1}{N^2}$ and $\beta = N^{3/2}$ are better than the scalings one might guess from theorem 2.1 ($\sqrt{\delta t}$ smaller than the order of $e^{-C_2}$ with $C_2$ an increasing function of $N$) and Remark 2.4 ($\beta \gg N^7$). We suspect from the numerical experiments that the scalings of $\beta = N^{3/2}, \delta t = \frac{1}{N^2}$ are tight bounds resulting in order one convergence, but do not have a proof as of yet.

6 Conclusion

We have shown with proposal size $\epsilon \to 0$ in the Metropolis Hastings algorithm, the Metropolis dynamics converges to the Langevin stochastic differential equation system. With proper scaling of $\beta = N^\alpha, \alpha > 1$ and the number of particles $N \to \infty$, the SDE system converges to the deterministic harmonic map heat flow equation.

Several future works are suggested by the results we have obtained. First, the scaling in the analysis is not optimal as suggested by the numerical simulations. One thought to improve the scaling in the calculation is to try to divide it into two situations: near equilibrium and out of equilibrium. When it is out of equilibrium, the drift part $P_\sigma^\perp(\Delta_N \sigma_i)$ of the SDE (13) should dominate. The Metropolis dynamics would also have a large probability of choosing a lower energy state as the proposal. In this sense both dynamics are close to the deterministic gradient descent. When it’s near equilibrium, the drift $P_\sigma^\perp(\Delta_N \sigma_i)$ in SDE is approximately zero and should behave like a Brownian motion in the neighborhood of equilibrium. The Metropolis dynamics with small proposal size would also stay in the neighborhood of the equilibrium state for a long time. We hope this kind of intuition could help lead to a better scaling in the future work.
Secondly, the SDE system we get is \( \mathbf{3} \) in Stratonovich sense. If we scale \( \beta = N^\alpha \), intuitively \( \alpha = 0 \) the noise part scales like \( \sqrt{\delta x} \sqrt{\delta t} \) as time-space white noise and \( 0 < \alpha < 1 \) gives colored noise. We would
Figure 4: Order of convergence for the error between M-H algorithm and Landau-Lifshitz equation with respect to lattice discretization size $\delta x = \frac{1}{N}$. From Figure 4 the error between M-H algorithm and Langevin equation dominates over the error between Langevin equation and Landau-Lifshitz equation. The order of convergence is expected to be $\delta t^{1/4} = \delta x$ since we choose $\delta t = \frac{1}{N^4}$ and it is approximately the case in (a) and (b). The analytical results in theorems 2.1 and 2.2 do not give as good convergence rate and demands worse scaling of $\delta t$, $\beta$ as function of $N$. The following parameters tested in numerical experiments are enough: Lattice length $L = 2$, initial space discretization $\delta x = \frac{1}{10}$, time step size for the M-H algorithm $\delta t = \frac{1}{N^3}$, inverse temperature $\beta = 1$, proposal size $\varepsilon = \sqrt{\frac{N \beta}{24}}$.

guess different scale of $\beta$ would lead the convergence result of a stochastic partial differential equation with white noise or colored noise. And as in [27, 5, 23] this convergence result might imply the optimal scaling of proposal size $\varepsilon$ in the Metropolis-Hastings algorithm. We note that as in [23], the drift term might become non-local through the influence of the colored noise, so this approach must be taken with some care.

A Drift and diffusion calculation

In this part we give the details of the error estimations. Here we state two simple inequalities that is used later. The first is

$$E \left[ |X + Y|^k \right] \leq C_k (E \left[ |X|^k \right] + E \left[ |Y|^k \right])$$

for some constant $C_k$ as $(X + Y)^k \leq (|X| \leq |Y|)^2 |Y|^k + (|X| > |Y|)^2 |X|^k$. Furthermore, this is also true for vectors

$$E \left[ \|X + Y\|^k \right] \leq C_k (E \left[ \|X\|^k \right] + E \left[ \|Y\|^k \right])$$

since $E \left[ \|X + Y\|^k \right] = E \left[ (\|X + Y\|^2)^{k/2} \right] \leq E \left[ (2\|X\|^2 + 2\|Y\|^2)^{k/2} \right] \leq 2^{k/2} C_k (E \left[ \|X\|^k \right] + E \left[ \|Y\|^k \right])$.

The second is Hölder inequality

$$E [XY] \leq E \|XY\| \leq E \|X\|^p \frac{1}{p} E \|Y\|^q \frac{1}{q}$$

with $\frac{1}{p} + \frac{1}{q} = 1$.

A.1 Exponential map

In Section 3.1 we use the notation:

$$\exp_{\sigma_i^n} (\varepsilon \nu_i^n) = \sigma_i^n + \varepsilon \nu_i^n + c_i^n = \sigma_i^n + \varepsilon \nu_i^n - \frac{1}{2} \varepsilon^2 (\nu_i^n \cdot \nu_i^n) \sigma_i^n + d_i^n.$$ 

Now we estimate $c_i^n, d_i^n$ as:

$$E \left[ ||c_i^n||^k \right] \leq C_k \varepsilon^{2k}, E \left[ ||d_i^n||^k \right] \leq D_k \varepsilon^{3k}$$
for any positive integer \( k \) and some constants \( C_k, D_k \) independent of \( i, n \).

Notice
\[
\exp_{\sigma_i} (\varepsilon \nu_i^n) = \frac{\sigma_i^n + \varepsilon \nu_i^n}{\| \sigma_i^n + \varepsilon \nu_i^n \|} + a_i^n = \frac{\sigma_i^n + \varepsilon \nu_i^n}{\sqrt{\| \sigma_i^n \|^2 + 2 \varepsilon \| \nu_i^n \|^2 - 2 \varepsilon (\sigma_i^n \cdot \nu_i^n)}} + a_i^n = \frac{\sigma_i^n + \varepsilon \nu_i^n}{\sqrt{1 + \varepsilon^2 \| \nu_i^n \|^2}} + a_i^n.
\]

Taylor expanding \( \frac{1}{\sqrt{1+\varepsilon^2 \| \nu_i^n \|^2}} \), we have
\[
\exp_{\sigma_i} (\varepsilon \nu_i^n) = (\sigma_i^n + \varepsilon \nu_i^n) \left[ 1 - \frac{\varepsilon^2}{2} \| \nu_i^n \|^2 + \eta_i^n \right] + a_i^n,
\]
where \( \eta_i^n \) is the remainder of the Taylor expansion for \( \frac{1}{\sqrt{1+\varepsilon^2 \| \nu_i^n \|^2}} \). Then,
\[
d_i^n = -\frac{\varepsilon^3}{2} \| \nu_i^n \|^2 \nu_i^n + (\sigma_i^n + \varepsilon \nu_i^n) \eta_i^n + a_i^n, \tag{71}
\]
\[
e_i^n = -\frac{\varepsilon^2}{2} \| \nu_i^n \|^2 \sigma_i^n + d_i^n + a_i^n. \tag{72}
\]

Let us first deal with the term \( a_i^n \), since the geodesic on the unit sphere is the great circle, \( \exp_{\sigma_i} (\varepsilon \nu_i^n) \), \( \frac{\sigma_i^n + \varepsilon \nu_i^n}{\| \sigma_i^n + \varepsilon \nu_i^n \|} \), are on the same great circle. The arc length of geodesic is \( \| \varepsilon \nu_i^n \| \), and the arc length of \( \frac{\sigma_i^n + \varepsilon \nu_i^n}{\| \sigma_i^n + \varepsilon \nu_i^n \|} \) is \( \arctan (\| \varepsilon \nu_i^n \|) \). The vector \( a_i^n \) is the straight line connecting the two points of the difference between these two arcs, and is bounded by the difference of arc lengths:
\[
\| a_i^n \| \leq \| \varepsilon \nu_i^n \| - \arctan (\| \varepsilon \nu_i^n \|).
\]

Taylor expanding for \( \arctan x \),
\[
\arctan x = x - \frac{x^3}{3} + r, r = \frac{f^{(4)}(\xi)}{4!} x^4, f^{(4)}(x) = \frac{24 x(1-x^2)}{(1+x^2)^4},
\]
and when \( x = \| \varepsilon \nu_i^n \| \geq 0, |f^{(4)}(x)| \leq \frac{24x}{(1+x^2)^2} \frac{1}{1+x^2} \leq 24, |r| \leq x^4 \). Hence, from \( x - \arctan x = \frac{x^3}{3} - r \),
\[
\| a_i^n \| \leq \| \varepsilon \nu_i^n \| - \arctan (\| \varepsilon \nu_i^n \|) \leq \frac{\| \varepsilon \nu_i^n \|^3}{3} + \| \varepsilon \nu_i^n \|^4,
\]
so
\[
\mathbb{E} \left[ \| a_i^n \|^k \right] \leq C \mathbb{E}_n \left[ \| \varepsilon \nu_i^n \|^{3k} \right] \leq C \varepsilon^{3k}.
\]

In the Taylor expansion for \( f(x) = \frac{1}{\sqrt{1+x^2}}, x \geq 0 \), the remainder \( r = f(x) - \left( 1 - \frac{x^2}{2} \right) \) is given by
\[
r = \frac{f''(\xi)}{2} x^2 = \frac{3}{8} (1 + \xi)^{-\frac{3}{2}} x^2, \xi \in [0, \infty)
\]
and \( |r| \leq \frac{3}{8} x^2 \). Applying the above estimates for \( r = \eta_i^n \) with \( x = \varepsilon^2 \| \nu_i^n \|^2 \geq 0 \), we observe
\[
|\eta_i^n| \leq \frac{3}{8 \varepsilon^4 \| \nu_i^n \|^4}.
\]

Now we could get the bound for the terms \( e_i^n, d_i^n \). The first term for \( d_i^n \) in (71) is bounded by
\[
\mathbb{E} \left[ \left\| \frac{\varepsilon^3}{2} \| \nu_i^n \|^2 \nu_i^n \right\|^k \right] \leq C \mathbb{E} \left[ \varepsilon^{3k} \| \nu_i^n \|^{3k} \right] \leq C \varepsilon^{3k}.
\]

The second term in (71) gives
\[
\mathbb{E} \left[ \left\| (\sigma_i^n + \varepsilon \nu_i^n) \eta_i^n \right\|^k \right] \leq \mathbb{E}_n \left[ \| \sigma_i^n + \varepsilon \nu_i^n \|^{2k} \right]^\frac{1}{2} \mathbb{E}_n \left[ |\eta_i^n|^{2k} \right]^\frac{1}{2} \leq C \varepsilon^{4k}
\]
by Hölder’s inequality. This is because the first term in the right hand side is bounded by

\[ E \left[ \| \sigma^n_i + \varepsilon \nu^n_i \|^2 \right] \leq C_1 \left( E \left[ \| \sigma^n_i \|^2 \right] + \varepsilon^{2k} E \left[ \| \nu^n_i \|^2 \right] \right) \leq C_1 + C_2 \varepsilon^{2k} \]

and the second term in the right hand side is bounded by

\[ E \left[ \| \eta^n_i \|^2 \right] \leq C E \left[ \varepsilon^{8k} \| \nu^n_i \|^8 \right] \leq C \varepsilon^{8k}. \]

The first term for \( c^n_i \) in (2)

\[ E \left[ \frac{\varepsilon^2}{2} \| \nu^n_i \| \| \sigma^n_i \| \right] \leq C \varepsilon^{2k} E \left[ \| \nu^n_i \|^2 \| \sigma^n_i \| \right] \leq C \varepsilon^{2k}. \]

The bound for \( E \left[ \| c^n_i \| \right], E \left[ \| d^n_i \| \right] \) are found using the inequalities

\[ E \left[ \| X + Y \|^k \right] \leq C_k \left( E \left[ \| X \|^k \right] + E \left[ \| Y \|^k \right] \right) \]

with the above bounds for the terms in \( c^n_i, d^n_i \).

### A.2 Drift

Now we give the error estimation for the drift calculation. Denote

\[ \theta^n_i \equiv E_n \left[ \sigma^{n+1}_i - \sigma^n_i \right] - \left( -\frac{1}{2} \beta \varepsilon^2 P \sigma^n_i \left( \frac{\partial H}{\partial \sigma^n_i} \right) - \varepsilon^2 \sigma^n_i \right). \]

We will show

\[ E \left[ \| \theta^n_i \|^2 \right] \leq C \varepsilon^6. \]

For simplicity we write \( \theta^n_i = \sum_k \theta^n_k \), where \( \theta^n_k \) denotes the error for each step of the drift calculation in Section 3.2. And we will show each \( E \left[ \| \theta^n_k \|^2 \right] \leq C \varepsilon^6 \).

Notice \( \theta^n_k \) are conditional expectations in the form of \( \theta^n_k = E_n \left[ X \right] \). Since \( f(x) = x^2 \) is a convex function, we have \( E_n \left[ X \right]^2 \leq E_n \left[ \| X \|^2 \right] \), hence

\[ E \left[ \| \theta^n_k \|^2 \right] = E \left[ \left( E_n \left[ X \right]\right)^2 \right] \leq E \left[ E_n \left[ \| X \|^2 \right] \right] = E \left[ \| X \|^2 \right]. \]

We will use this to bound \( E \left[ \| \theta^n_k \|^2 \right] \).

In the drift calculation, we first take the approximation \( E_n \left[ \sigma^{n+1}_i - \sigma^n_i \right] \approx E_n \left[ \left( \varepsilon^2 \frac{\nu^n_i \cdot \nu^n_i}{2} \sigma^n_i \right) \left( 1 \wedge e^{-\beta \delta H} \right) \right]. \)

Denote the difference of them as

\[ \theta_1 \equiv E_n \left[ \sigma^{n+1}_i - \sigma^n_i \right] - E_n \left[ \left( \varepsilon^2 \frac{\nu^n_i \cdot \nu^n_i}{2} \sigma^n_i \right) \left( 1 \wedge e^{-\beta \delta H} \right) \right] = E_n \left[ d^n_i \left( 1 \wedge e^{-\beta \delta H} \right) \right], \]

then by Hölder’s inequality

\[ E \left[ \| \theta_1 \|^2 \right] \leq E \left[ \left\| d^n_i \left( 1 \wedge e^{-\beta \delta H} \right) \right\|^2 \right] \leq C E \left[ \left\| d^n_i \right\|^4 \right]^{\frac{1}{2}} E \left[ \left( 1 \wedge e^{-\beta \delta H} \right)^4 \right]^{\frac{1}{2}} \leq C \varepsilon^6. \]

For the second term in drift \( E_n \left[ \left( \frac{\varepsilon^2}{2} (\nu^n_i \cdot \nu^n_i) \sigma^n_i \right) \left( 1 \wedge e^{-\beta \delta H} \right) \right] \approx E_n \left[ \left( \frac{\varepsilon^2}{2} (\nu^n_i \cdot \nu^n_i) \sigma^n_i \right) \right] \), denote the error term as

\[ \theta_2 \equiv E_n \left[ \left( \frac{\varepsilon^2}{2} (\nu^n_i \cdot \nu^n_i) \sigma^n_i \right) \right] - E_n \left[ \left( \frac{\varepsilon^2}{2} (\nu^n_i \cdot \nu^n_i) \sigma^n_i \right) \right] = E_n \left[ \left( \frac{\varepsilon^2}{2} (\nu^n_i \cdot \nu^n_i) \sigma^n_i \right) \left( 1 \wedge e^{-\beta \delta H} - 1 \right) \right]. \]

We have \(|(1 + \varepsilon^2) - 1| \leq |x|, \) and \( |\delta H| \leq C \sum_j \left( \| \nu^n_j \| + \| \nu^n_j \|^2 + \| c^n_j \| \right) \) so by Hölder inequality

\[ E \left[ \| \theta_2 \|^2 \right] \leq E \left[ \left\| \frac{\varepsilon^2}{2} (\nu^n_i \cdot \nu^n_i) \sigma^n_i \right\|^4 \right]^{\frac{1}{2}} E \left[ \left( 1 \wedge e^{-\beta \delta H} - 1 \right)^4 \right]^{\frac{1}{2}} \leq C E \left[ \varepsilon^8 \| \nu^n \|^8 \| \sigma^n_i \|^4 \right]^{\frac{1}{2}} E \left[ \| \delta H \|^4 \right]^{\frac{1}{2}} \leq C \beta^2 \varepsilon^6. \]
Next we replace $\delta H$ by $\varepsilon \frac{\partial H}{\partial \sigma_i} \cdot \nu_i^n + R_i^n$ in the drift calculation. Define
\[
\theta_3 \equiv E_n \left[ \varepsilon \nu_i^n \left( 1 \& e^{-\varepsilon H} \right) \right] - E_n \left[ \varepsilon \nu_i^n \left( 1 \& e^{-\varepsilon \left( \frac{\partial H}{\partial \sigma_i} \cdot \nu_i^n + R_i^n \right)} \right) \right].
\]
Notice that $\delta H = \varepsilon \frac{\partial H}{\partial \sigma_i} \cdot \nu_i^n + R_i^n + h_i^n$ and $\left( 1 \& e^{\varepsilon H} \right) - \left( 1 \& e^{\varepsilon \left( \frac{\partial H}{\partial \sigma_i} \cdot \nu_i^n + R_i^n \right)} \right)$, hence
\[
E \left[ \| \theta_3 \|^2 \right] \leq E \left[ \| \varepsilon \nu_i^n \|^4 \right] \frac{1}{2} E \left[ \left( \beta h_i^n \right)^4 \right] \frac{1}{2}.
\]
Since $|h_i^n| \leq C \sum_j \left( \| \varepsilon \nu_j^n \|^2 + \| e^{\varepsilon \sigma_j} \| \right)$, we have $E \left[ \left( h_i^n \right)^4 \right] \leq CE^8$ and
\[
E \left[ \| \theta_4 \|^2 \right] \leq E \left[ \| \varepsilon \nu_i^n \|^4 \right] \frac{1}{2} E \left[ \left( \beta h_i^n \right)^4 \right] \frac{1}{2} \leq C \beta^2 \varepsilon^6.
\]
Then we write the drift term as in (24), and have the first term given by
\[
E \left[ \varepsilon r_1 b_1 \left( 1 \& e^{-\varepsilon \left( \xi + \frac{\partial H}{\partial \sigma_i} \cdot b_1 + \varepsilon \frac{\partial H}{\partial \sigma_i} \cdot b_2 + R_i^n \right)} \right) \right] R_i^n, r_2
\]
\[
= - \varepsilon \beta e^2 \left( \frac{\partial H}{\partial \sigma_i} \cdot b_1 \right) b_1 \frac{\xi + \varepsilon \frac{\partial H}{\partial \sigma_i} \cdot b_2 + \beta R_i^n}{\xi \varepsilon \frac{\partial H}{\partial \sigma_i} \cdot b_1} \Phi \left( \frac{\varepsilon r_2 \frac{\partial H}{\partial \sigma_i} \cdot b_2 + R_i^n}{\xi \varepsilon \frac{\partial H}{\partial \sigma_i} \cdot b_1} \right) - \beta e^2 \left( \frac{\partial H}{\partial \sigma_i} \cdot b_1 \right).
\]
We approximate $e^\xi \frac{\partial H}{\partial \sigma_i} \cdot b_2 + \beta R_i^n$ by 1 in the above equation and bound the following term
\[
\theta_4 \equiv E_n \left[ - \varepsilon \beta e^2 \left( \frac{\partial H}{\partial \sigma_i} \cdot b_1 \right) b_1 \left( \frac{\partial H}{\partial \sigma_i} \cdot b_2 + \beta R_i^n \right) \Phi \left( \frac{\varepsilon r_2 \frac{\partial H}{\partial \sigma_i} \cdot b_2 + R_i^n}{\xi \varepsilon \frac{\partial H}{\partial \sigma_i} \cdot b_1} \right) - \beta e^2 \left( \frac{\partial H}{\partial \sigma_i} \cdot b_1 \right) \right]
\]
\[
= E_n \left[ - \varepsilon \beta e^2 \left( \frac{\partial H}{\partial \sigma_i} \cdot b_1 \right) b_1 \Phi \left( \frac{\varepsilon r_2 \frac{\partial H}{\partial \sigma_i} \cdot b_2 + R_i^n}{\xi \varepsilon \frac{\partial H}{\partial \sigma_i} \cdot b_1} \right) - \beta e^2 \left( \frac{\partial H}{\partial \sigma_i} \cdot b_1 \right) \right]
\]
by
\[
E_n \left[ \| \theta_4 \|^2 \right] \leq C \varepsilon^6.
\]
For $z \sim N(\mu, \sigma^2)$, we use
\[
E \left[ |z^k| \right] = E \left[ |z^k| \mathbb{1}(z \leq 2) \right] + E \left[ |z^k| \mathbb{1}(z > 2) \right].
\]
For the first term in (73), since $|z^k - 1| \leq \varepsilon z^k |z \leq 2|$, we have
\[
E \left[ |z^k - 1| \mathbb{1}(z \leq 2) \right] \leq \varepsilon k E \left[ |z^k| \right].
\]
When $k = 4$, $E \left[ z^k \right] = \mu^4 + 6\mu^2 \sigma^2 + 3\sigma^4$. For the second term in (73), $|z^k - 1| \leq \varepsilon z^k$ when $z > 2$, suppose $2 + \mu + k\sigma^2 \geq 1$ we have
\[
E_n \left[ e^{\varepsilon z^k} \mathbb{1}(z > 2) \right] = \int_2^\infty \frac{1}{\sqrt{2\pi \sigma^2}} e^{\frac{(z-\mu)^2}{2\sigma^2}} \varepsilon z^k e^{-\frac{(z-\mu)^2}{2\sigma^2}} dz
\]
\[
= \int_2^\infty \frac{1}{\sqrt{2\pi \sigma^2}} e^{\mu + \frac{k^2 \sigma^2}{2}} e^{-\frac{(z-\mu-k^2 \sigma^2)^2}{2\sigma^2}} dz = e^{\mu + \frac{k^2 \sigma^2}{2}} \int_{2+\mu+k\sigma^2}^{\infty} \frac{1}{\sqrt{2\pi \sigma^2}} e^{-\frac{x^2}{2\sigma^2}} dx
\]
\[
\leq e^{\mu + \frac{k^2 \sigma^2}{2}} \int_{2+\mu+k\sigma^2}^{\infty} \frac{1}{\sqrt{2\pi \sigma^2}} e^{-\frac{x^2}{2\sigma^2}} dx = e^{\mu + \frac{k^2 \sigma^2}{2}} \int_{2+\mu+k\sigma^2}^{\infty} \frac{2}{\pi} e^{-\frac{x^2}{2\sigma^2}} dx
\]
\[
\leq e^{\mu + \frac{k^2 \sigma^2}{2}} \frac{2}{\pi} e^{-\frac{1}{2\sigma^2}}.
\]
Notice that  \( \left( \frac{\beta \varepsilon \partial H}{\partial \sigma_i} b_1 \right)^2 + \beta \varepsilon \varepsilon b_2 + \beta R_i^n \sim N(\varepsilon^2, \varepsilon^2) \), when \( \varepsilon \) is small \( 2 + \mu + k\sigma^2 \geq 1 \), hence we get

\[
E \left[ \left( \frac{\beta \varepsilon \partial H}{\partial \sigma_i} b_1 \right)^2 + \beta \varepsilon \varepsilon b_2 + \beta R_i^n - 1 \right] \leq \varepsilon^2 \varepsilon^4 + \frac{2C}{\pi} \varepsilon e^{-\frac{1}{2v^2\varepsilon^2}} \leq C \varepsilon^4
\]

as the term \( e^{-\frac{1}{2v^2\varepsilon^2}} \) decays faster than any polynomial of \( \varepsilon \) as \( \varepsilon \to 0 \).

So we have

\[
E \left[ \| \theta_4 \|^2 \right] = E \left[ -\beta^2 \left( \frac{\partial H}{\partial \sigma_i} \cdot b_1 \right) b_1 \Phi \left( \frac{\varepsilon b_2 + R_i^2}{\varepsilon b_2 + R_i^2} \cdot b_1 \right) \right] \leq C \varepsilon^4 \varepsilon^2.
\]

Then we approximate \( \Phi \left( \frac{\varepsilon b_2 + R_i^2}{\varepsilon b_2 + R_i^2} \cdot b_1 \right) \) by \( \Phi \left( \frac{\varepsilon b_2 + R_i^2}{\varepsilon b_2 + R_i^2} \cdot b_1 \right) \) in the calculation. Denote

\[
\theta_5 \equiv E \left[ -\beta^2 \left( \frac{\partial H}{\partial \sigma_i} \cdot b_1 \right) b_1 \Phi \left( \frac{\varepsilon b_2 + R_i^2}{\varepsilon b_2 + R_i^2} \cdot b_1 \right) \right] - \varepsilon \Phi \left( \frac{\varepsilon b_2 + R_i^2}{\varepsilon b_2 + R_i^2} \cdot b_1 \right).
\]

From \( |\Phi(x + \delta x) - \Phi(x)| = |\Phi'(x)\delta x| = e^{-\frac{\beta \varepsilon \varepsilon^2}{\delta x}} \delta x | | \delta x | \), we have

\[
E \left[ \theta_5^2 \right] = E \left[ -\beta^2 \left( \frac{\partial H}{\partial \sigma_i} \cdot b_1 \right) b_1 \right] \leq C \varepsilon^4 \varepsilon^2.
\]

Similarly we would get the bound for

\[
E \left[ \varepsilon \varepsilon b_2 \left( 1 \wedge e^{-\beta \left( \varepsilon \left( \sigma_i \cdot b_1 + \varepsilon \varepsilon b_2 + R_i^2 \right) \right) } \right) \right]
\]

and see every \( E \left[ \| \theta_i \|^2 \right] \) is bounded by \( C \varepsilon^6 \) so \( E \left[ \| \theta_i \|^2 \right] \leq C \varepsilon^6 \).

### A.3 Diffusion

Here we are show that \( E \left[ \| \phi_i \|^2 \right] \sim O(\varepsilon^3) \). In

\[
E \left[ \| \phi_i \|^2 \right] = E \left[ \| \sigma_i^{n+1} - \sigma_i^n \|^2 (1 - e^{-\beta H}) \right] + E \left[ \| \varepsilon \varepsilon b_2 \left( 1 \wedge e^{-\beta \left( \varepsilon \left( \sigma_i \cdot b_1 + \varepsilon \varepsilon b_2 + R_i^2 \right) \right) } \right) \right]
\]

28
every term is order $\varepsilon^4$ except for $\mathbb{E} [\varepsilon^2 \|\nu^\alpha_n\|^2 (1 - (1 \wedge e^{-\beta H}))]$. We show

$$
\mathbb{E} [\|\nu^\alpha_n\|^2 (1 \wedge e^{-\beta H})] = \mathbb{E} [\|\nu^\alpha_n\|^2] + O(\varepsilon).
$$

Indeed, since $|1(1 \wedge e^x) - (1 \wedge (1 + x))| \leq x^2$,

$$
\mathbb{E} [\|\nu^\alpha_n\|^2 \left(1 \wedge e^{-\beta \left(\frac{\partial H}{\partial \sigma_1^n} \cdot \nu^\alpha_n + R^n\right)}\right)] \\
\approx \mathbb{E} [\|\nu^\alpha_n\|^2 \left(1 \wedge \left(1 - \beta \left(\frac{\partial H}{\partial \sigma_1^n} \cdot \nu^\alpha_n + R^n\right)\right)\right)] + O(\varepsilon^2) \\
= \mathbb{E} [\|\nu^\alpha_n\|^2] - \mathbb{E} [\|\nu^\alpha_n\|^2 \left(\beta \left(\frac{\partial H}{\partial \sigma_1^n} \cdot \nu^\alpha_n + R^n\right)\right) \mathbb{I}\{\beta (\frac{\partial H}{\partial \sigma_1^n} \cdot \nu^\alpha_n + R^n) > 0\}],
$$

Then it remains to show $\mathbb{E} [\|\nu^\alpha_n\|^2 \left(\beta \left(\frac{\partial H}{\partial \sigma_1^n} \cdot \nu^\alpha_n + R^n\right)\right) \mathbb{I}\{\beta (\frac{\partial H}{\partial \sigma_1^n} \cdot \nu^\alpha_n + R^n) > 0\}]$ is approximately an $O(\varepsilon)$ term. As before take $\nu^\alpha_n = r_1 b_1 + r_2 b_2$ and we will only take care of $r_1$, since the calculation for $r_2$ is similar. Denote $R \equiv R^n + \frac{\partial H}{\partial \sigma_1^n} \cdot b_2 r_2 \sim N(0, \varepsilon^2 c_1^2), c_1 \sim O(1)$. The expectation of the $r_1$ part is

$$
-\beta \mathbb{E} \left[ r_1^2 \left( R + \varepsilon \frac{\partial H}{\partial \sigma_1^n} \cdot b_1 r_1 \right) \mathbb{I}\{\beta (\frac{\partial H}{\partial \sigma_1^n} \cdot b_1 r_1 + R) > 0\}\right].
$$

To calculate, first condition on $R$ and compute it over $r_1$. This involves expectations in forms of

$$
\mathbb{E} \left[ z^2 \mathbb{I}_{[a(z+b)>a]} \right], \quad \mathbb{E} \left[ z^3 \mathbb{I}_{[a(z+b)>a]} \right].
$$

For $z \sim N(0,1)$, a direct calculation gives

$$
\mathbb{E} \left[ z^2 \mathbb{I}_{[a(z+b)>a]} \right] = \frac{-b}{\sqrt{2\pi} |a|} e^{-\frac{b^2}{2\sigma^2}} + \Phi \left( \frac{b}{|a|} \right), \\
\mathbb{E} \left[ z^3 \mathbb{I}_{[a(z+b)>a]} \right] = \frac{1}{\sqrt{2\pi}} \left(2 + \frac{b^2}{a^2}\right) e^{-\frac{b^2}{2\sigma^2}} \text{sign}(a).
$$

Using the tower property, we have

$$
\mathbb{E} \left[ r_1^2 \left( R + \varepsilon \frac{\partial H}{\partial \sigma_1^n} \cdot b_1 r_1 \right) \mathbb{I}\{\beta (\frac{\partial H}{\partial \sigma_1^n} \cdot b_1 r_1 + R) > 0\}\right] \\
= \mathbb{E}_n \left[ r_1^2 R \mathbb{I}\{\beta (\frac{\partial H}{\partial \sigma_1^n} \cdot b_1 r_1 + R) > 0\}\right] + \mathbb{E}_n \left[ \varepsilon \frac{\partial H}{\partial \sigma_1^n} \cdot b_1 (r_1)^3 \mathbb{I}\{\beta (\frac{\partial H}{\partial \sigma_1^n} \cdot b_1 r_1 + R) > 0\}\right].
$$

Denote $c_2 = \frac{\partial H}{\partial \sigma_1^n} \cdot b_1$, for the first term in (75), the first formula in (74) gives

$$
\mathbb{E}_n \left[ r_1^2 R \mathbb{I}\{\beta (\frac{\partial H}{\partial \sigma_1^n} \cdot b_1 r_1 + R) > 0\}\right] = \mathbb{E}_n \left[ \frac{R^2}{\sqrt{2\pi} |c_2|} e^{-\frac{R^2}{2\varepsilon c_2^2}} + R \Phi \left( \frac{R}{|c_2|} \right) \right].
$$

For the second term in (75), the second formula in (74) gives

$$
\mathbb{E}_n \left[ \varepsilon \frac{\partial H}{\partial \sigma_1^n} \cdot b_1 (r_1)^3 \mathbb{I}\{\beta (\frac{\partial H}{\partial \sigma_1^n} \cdot b_1 r_1 + R) > 0\}\right] = \mathbb{E}_n \left[ \varepsilon c_2 \frac{1}{\sqrt{2\pi}} \left(2 + \frac{R^2}{\varepsilon c_2^2}\right) e^{-\frac{R^2}{2\varepsilon c_2^2}} \text{sign}(c_2) \right]
$$

Combining (70) and (77), we have

$$
\mathbb{E}_n \left[ r_1^2 \left( R + \varepsilon \frac{\partial H}{\partial \sigma_1^n} \cdot b_1 r_1 \right) \mathbb{I}\{\beta (\frac{\partial H}{\partial \sigma_1^n} \cdot b_1 r_1 + R) > 0\}\right] = \mathbb{E}_n \left[ R \Phi \left( \frac{R}{|c_2|} \right) \right] + \mathbb{E}_n \left[ \frac{2\varepsilon |c_2|}{\sqrt{2\pi}} e^{-\frac{R^2}{2\varepsilon c_2^2}} \right].
$$
Since $R\left(\Phi\left(\frac{R}{|c_2|}\right) - \frac{1}{2}\right) \geq 0$, the first term $E_n\left[R\Phi\left(\frac{R}{|c_2|}\right)\right] = E_n\left[R\left(\Phi\left(\frac{R}{|c_2|}\right) - \frac{1}{2}\right) + \frac{1}{2}R\right] \geq 0$. In the second term $\frac{d}{c_2} \sim N(0, \epsilon^2)$ and 

$$E_n\left[e^{-\frac{d^2}{2|c_2|^2}}\right] = \frac{c_2}{\sqrt{c_1 + c_2}} \sim O(1)$$

after a direct calculation. This shows 

$$-\beta E_n\left[r_1^2\left(R + \epsilon \frac{\partial H}{\partial \sigma_i} \cdot b_i r_1\right) \mathbb{I}\{\epsilon \frac{\partial H}{\partial \sigma_i} \cdot b_i r_1 > 0\}\right] \sim O(\epsilon)$$

and the $r_2$ part follows similarly.

Thus we conclude $E\left[||\nu||^2\left(\beta \left(\epsilon \frac{\partial H}{\partial \sigma_i} \cdot \nu_i + R_i\right)\right) \mathbb{I}\{\epsilon \frac{\partial H}{\partial \sigma_i} \cdot \nu_i + R_i > 0\}\right]$ is an $\epsilon$ term.

**B Quadratic variation**

For an $n$ dimensional process $X$

$$dX = \mu dt + \sigma dW.$$ 

Itô’s chain rule for a function $f(X)$ is

$$df(X_1, X_2, \ldots, X_n) = \sum_i \frac{\partial f}{\partial X_i} dX_i + \frac{1}{2} \sum_i \sum_j \frac{\partial^2 f}{\partial X_i \partial X_j} d[X_i, X_j](t).$$

where

$$d[X_i, X_j](t) = a_{ij} dt, \quad a = \sigma \sigma^T.$$ 

For $H = J \sum_{i,j>1} ||\sigma_i - \sigma_j||^2$, denote $i,j$ as $i,j$-th spin and $\alpha, \beta = x, y, z$ for the coordinates of the spin

$$dH = \sum_{i,\alpha} \frac{\partial H}{\partial \sigma_i^\alpha} d\sigma_i^\alpha + \frac{1}{2} \sum_{i,j,\alpha,\beta} \frac{\partial^2 H}{\partial \sigma_i^\alpha \partial \sigma_j^\beta} d[\sigma_i^\alpha, \sigma_j^\beta]$$

where

$$\frac{\partial H}{\partial \sigma_i^\alpha} = -2 J N^2 \triangle_N \sigma_i^\alpha, \quad \frac{\partial^2 H}{\partial (\sigma_i^\alpha)^2} = \begin{cases} 4J & j = i \\ -2J & j = \pm 1 \\ 0 & \text{otherwise} \end{cases}$$

and $\frac{\partial^2 H}{\partial \sigma_i^\alpha \sigma_i^\alpha} = 0$. The results for $y, z$ are similar.

The noise term in SDE is $P_{\sigma_i}^\perp(dW_i) = dW_i - (dW_i, \sigma_i)\sigma_i$. For $i \neq j$, $W_i, W_j$ are independent and then $d[\sigma_i^\alpha, \sigma_j^\beta] = 0$, so only $d[\sigma_i^x, \sigma_i^x]$ need to be calculated. Since $W_i^x, W_i^y, W_i^z$ are also independent, the quadratic variation is calculated by summing up the coefficients before each $dW_i^x$

$$d[\sigma_i^x, \sigma_i^x] = \epsilon^2 \left[ (1 - (\sigma_i^x)^2)^2 + (\sigma_i^x \sigma_i^y)^2 + (\sigma_i^x \sigma_i^z)^2 \right] dt = \epsilon^2 \left[ 1 - (\sigma_i^x)^2 \right] dt,$$

$$d[\sigma_i^y, \sigma_i^y] = \epsilon^2 \left[ (1 - (\sigma_i^y)^2)^2 + (\sigma_i^y \sigma_i^x)^2 + (\sigma_i^y \sigma_i^z)^2 \right] dt = \epsilon^2 \left[ 1 - (\sigma_i^y)^2 \right] dt,$$

$$d[\sigma_i^z, \sigma_i^z] = \epsilon^2 \left[ (1 - (\sigma_i^z)^2)^2 + (\sigma_i^z \sigma_i^x)^2 + (\sigma_i^z \sigma_i^y)^2 \right] dt = \epsilon^2 \left[ 1 - (\sigma_i^z)^2 \right] dt.$$ 

As $(\sigma_i^x)^2 + (\sigma_i^y)^2 + (\sigma_i^z)^2 = 1$, the Itô correction is

$$\frac{1}{2} 4J \epsilon^2 \sum_i \left[ 1 + 1 + 1 - (\sigma_i^x)^2 - (\sigma_i^y)^2 - (\sigma_i^z)^2 \right] = \frac{1}{2} \sum_i 4J * 2\epsilon^2 = 4J N \epsilon^2$$

and from (79)

$$dH = \sum_i -\frac{2J}{N^2} \triangle_N \sigma_i \cdot \left[ \left( \frac{JN}{N^2} P_{\sigma_i}^\perp (\triangle_N \sigma_i(t)) dt - \epsilon^2 \sigma_i(t) dt + P_{\sigma_i}^\perp (edW_i(t)) \right) \right] + 4J N \epsilon^2.$$ 

30
Denote $M_t$ as the martingale given by
\[ dM_t = \sum_i \frac{2J}{N^2} \Delta_N \sigma_i \cdot P^\perp_{\sigma_i} (\epsilon dW_i(t)) \]  
(80)
and $\langle M \rangle_t$ the corresponding quadratic variation. The quantity $d\langle M \rangle_t$ is calculated by summing the square of the coefficients of $dW_i$ in $x, y, z$ components:
\[ d\langle M \rangle_t = d \left( \sum_i -\frac{2J}{N^2} \Delta_N \sigma_i \cdot P^\perp_{\sigma_i} (\epsilon dW_i(t)) \right)_t = d \left( \sum_i -\frac{2J}{N^2} \Delta_N \sigma_i \cdot [dW_i - (dW_i \cdot \sigma_i) \sigma_i] \right)_t \]
\[ = \sum_i \frac{4J^2 \epsilon^2}{N^4} \left( \sum_{\alpha=x,y,z} (\Delta_N \sigma_i - (\Delta_N \sigma_i \cdot \sigma_i))_{\alpha} \right)^2 dt = \sum_i \frac{4J^2 \epsilon^2}{N^4} \left\| P^\perp_{\sigma_i} (\Delta_N \sigma_i) \right\|^2 dt, \]
for the last step $P^\perp_{\sigma_i} (\Delta_N \sigma_i) = \Delta_N \sigma_i - (\Delta_N \sigma_i \cdot \sigma_i) \sigma_i$.

Then the inequality for continuous $L^2$ martingale $M_t$
\[ \mathbb{P} (\sup (M_t - \alpha/2 \langle M \rangle_t) > \beta) \leq e^{-\alpha \beta} \]  
(81)
is used to get a bound on $H$.

Notice in (80), we have
\[ \Delta_N \sigma_i \cdot \left( P^\perp_{\sigma_i} (\Delta_N \sigma_i) \right) = \left\| P^\perp_{\sigma_i} (\Delta_N \sigma_i) \right\|^2. \]

We can write it in the form of $d\langle M \rangle_t$ by observing
\[ dH = dM_t - \frac{N}{2 \epsilon^2} d\langle M \rangle_t + \left[ \sum_i \epsilon^2 \frac{2J}{N^2} \Delta_N \sigma_i \cdot \sigma_i + 4JN \epsilon^2 \right] dt \]
and the last term in the bracket
\[ \sum_i \epsilon^2 \frac{2J}{N^2} \Delta_N \sigma_i \cdot \sigma_i + 4JN \epsilon^2 \leq \sum_i \frac{2J \epsilon^2 (\sigma_{i+1} + \sigma_{i-1}) \cdot \sigma_i}{4JN} \leq 4JN \epsilon^2. \]

So
\[ H_N(t) = H_N(0) + M_t - \frac{N}{2 \epsilon^2} \langle M \rangle_t + \int \left[ \sum_i \epsilon^2 \frac{2J}{N^2} \Delta_N \sigma_i \cdot \sigma_i + 4JN \epsilon^2 \right] ds \]
\[ \leq H_N(0) + M_t - \frac{N}{2 \epsilon^2} \langle M \rangle_t + 4JN \epsilon^2 Nt. \]

Take $\alpha = \frac{N}{2 \epsilon^2}$ in the inequality $\mathbb{P} (\sup (M_t - \alpha/2 \langle M \rangle_t) > \beta) \leq e^{-\alpha \beta}$,
\[ \mathbb{P} \left( \sup_{t \leq T} H_N \geq H_N(0) + 4JN \epsilon^2 T + \beta \right) \leq \mathbb{P} \left( \sup_{t \leq T} M_t - \frac{N}{2 \epsilon^2} \langle M \rangle_t \geq \beta \right) \leq e^{-\frac{\beta N}{\epsilon^2}}. \]  
(82)

C Diffusion on sphere

We will use Fokker-Planck equation to show the Stratonovich SDE
\[ dx = P^\perp_x (dW) \]  
(83)
in $\mathbb{R}^2$ and $\mathbb{R}^3$ are describing Brownian motion on the unit circle and unit sphere. And in $\mathbb{R}^3$ it is regardless of the choice for $P^\perp_x (y) = x \times y$ or $P^\perp_x (y) = -x \times (x \times y) = I - xx^T$. 

31
C.1 Circle $S^1$

For a Stratonovich SDE with the form
\[ dX_i = b_i dt + \sum_j \sigma_{ij} dW_j, \]
the corresponding Itô drift coefficient is
\[ \tilde{b}_i = b_i + \frac{1}{2} \sum_j \sum_k \frac{\partial \sigma_{ij}}{\partial x_k} \sigma_{kj}. \]  
(84)

On the circle $P^\perp_x (dW) = (I - xx^T) dW = dW - (dW, x)x$. The corresponding Itô form for $P^\perp_x$ is
\[ dx = -\frac{1}{2} x + (I - xx^T) dW. \]  
(85)

For Itô SDE $dx = \mu(x, t) dt + \sigma(x, t) dW$, the Fokker-Planck equation is
\[ \frac{\partial \rho}{\partial t} = -\sum_i \frac{\partial}{\partial x_i} (\mu_i \rho) + \frac{1}{2} \sum_i \sum_j \frac{\partial^2}{\partial x_i \partial x_j} (D_{ij} \rho), \]
with diffusion tensor
\[ D_{ij} = \sum_k \sigma_{ik} \sigma_{jk} = (\sigma \sigma^T)_{ij}. \]
(86)

The Laplacian on the circle in polar coordinate is $\partial_{\theta \theta} \rho = (\partial_x \rho_y - \partial_y \rho_x)^2$. Use transformation $x = r \cos \theta, y = r \sin \theta$, $\partial_{\theta \theta} = (-y \partial_x + x \partial_y)(-y \partial_x + x \partial_y) = y^2 \partial_x^2 + x^2 \partial_y^2 - 2xy \partial_x \partial_y - x \partial_x - y \partial_y$

Corresponding to the Fokker-Planck equation above.

C.2 Sphere $S^2$

In the sphere case, the projection can take the following two forms
\[ P^\perp_x(y) = \begin{cases} x \times y \\ -x \times (x \times y) = (I - xx^T)y \end{cases}. \]

In both cases the Itô correction are the same as $-x$. The Itô form for $P^\perp_x$ is
\[ dx = -xdt + P^\perp_x (dW). \]  
(88)

In the Fokker-Planck equation calculation, for both projections the diffusion tensor are the same
\[ D = \begin{pmatrix} y^2 + z^2 & -x & -z \\ -x & x^2 + z^2 & -y \\ -z & -y & x^2 + y^2 \end{pmatrix} \]

Using the fact $x^2 + y^2 + z^2 = 1$. The Fokker-Planck equation is
\[ \partial_t \rho = \frac{1}{2} \left[ (y^2 + z^2) \rho_{xx} + (x^2 + z^2) \rho_{yy} + (x^2 + y^2) \rho_{zz} - \partial_x(xy \rho_y + xz \rho_z) - \partial_y(xy \rho_x + yz \rho_z) - \partial_z(xz \rho_x + yz \rho_y) \right]. \]
The Laplacian on $S^2$ in polar coordinate is

$$\frac{1}{\sin \theta} \partial_\theta (\sin \theta \partial_\theta) + \frac{1}{\sin^2 \theta} \partial^2_\phi.$$ 

Using the change of coordinate

$$\begin{cases} 
  x = r \sin \theta \cos \phi \\
  y = r \sin \theta \sin \phi \\
  z = r \cos \theta
\end{cases},$$

we have

$$\partial_\theta = \frac{xz}{\sqrt{1-z^2}} \partial_x + \frac{yz}{\sqrt{1-z^2}} \partial_y - \sqrt{1-z^2} \partial_z$$

$$\partial^2_\theta = \frac{x^2 z^2}{1-z^2} \partial^2_x + \frac{y^2 z^2}{1-z^2} \partial^2_y + 2 \frac{xyz}{1-z^2} \partial^2_{xy} - 2 xz \partial^2_{xz} - 2 yz \partial^2_{yz} - x \partial_x - y \partial_y + (1-z^2) \partial^2_z - z \partial_z$$

$$\partial^2_\phi = (\partial_x + y \partial_y) (\partial_x + x \partial_y) = y^2 \partial^2_x + x^2 \partial^2_y - 2xy \partial_x \partial_y - x \partial_x - y \partial_y.$$

As $x^2 + y^2 + z^2 = 1$, $\sin^2 \theta = x^2 + y^2$, $\cos \theta \sin \theta = \frac{z}{\sqrt{x^2+y^2}}$, the equation

$$\partial_t \rho = \frac{1}{\sin \theta} \partial_\theta (\sin \theta \partial_\theta \rho) + \frac{1}{\sin^2 \theta} \partial^2_\phi \rho$$

is corresponding to the Fokker-Planck equation above.
