Resonant CP Violation in Higgs Radiation
at $e^+e^-$ Linear Collider

ABSTRACT
We study resonant CP violation in the Higgsstrahlung process $e^+e^- \rightarrow H_{1,2,3}$ ($Z \rightarrow e^+e^-, \mu^+\mu^-$) and subsequent decays $H_{1,2,3} \rightarrow b\bar{b}$, $\tau^-\tau^+$, in the MSSM with Higgs-sector CP violation induced by radiative corrections. At a high-energy $e^+e^-$ linear collider, the recoil-mass method enables one to determine the invariant mass of a fermion pair produced by Higgs decays with a precision as good as 1 GeV. Assuming an integrated luminosity of 100 fb$^{-1}$, we show that the production lineshape of a coupled system of neutral Higgs bosons decaying into $b\bar{b}$ quarks is sensitive to the CP-violating parameters. When the Higgs bosons decay into $\tau^-\tau^+$, two CP asymmetries can be defined using the longitudinal and transverse polarizations of the $\tau$ leptons. Taking into account the constraints from electric dipole moments, we find that these CP asymmetries can be as large as 80%, in a tri-mixing scenario where all three neutral Higgs states of the MSSM are nearly degenerate and mix significantly.
1 Introduction

A future $e^+e^−$ linear collider, such as the projected International Linear Collider (ILC), will have the potential to probe the Standard Model (SM) Higgs sector with higher precision than its predecessors, the Tevatron collider at Fermilab and the Large Hadron Collider (LHC) at CERN. The present direct search limits from the search for Higgsstrahlung [1] at LEP show that the SM Higgs boson should be heavier than about 114 GeV [2]. This lower limit is within the mass range favoured indirectly by precision electroweak measurements [3]. Future refinements of these direct and indirect limits will be very crucial for identifying the underlying structure of the fundamental Higgs sector, within either the SM or some non-minimal model of Higgs physics.

One well-motivated model of physics beyond the SM is the minimal supersymmetric extension of the Standard Model (MSSM) [4]. The MSSM predicts three neutral Higgs states. In the presence of explicit CP-violating sources, such as complex soft squark masses, gaugino masses and trilinear couplings, all the three neutral Higgs bosons mix through CP-violating quantum effects [5–9] to mass eigenstates, $H_{1,2,3}$, of indefinite CP. In this CP-violating MSSM, one interesting possibility is that the lightest neutral Higgs boson could be considerably lighter than 114 GeV [10, 11], at moderate values of $\tan β \lesssim 10$, for relatively light charged Higgs-boson masses, $M_{H^±} \sim 130–170$ GeV. Alternatively, if $\tan β \gtrsim 40$, all three neutral Higgs states $H_{1,2,3}$ may have similar masses and strongly mix with each other dynamically, through CP-violating off-diagonal absorptive self-energy effects [12,13]. Such a scenario was studied in [13–15] and termed the CP-violating tri-mixing scenario of the MSSM.

The general unconstrained MSSM has dozens of additional CP-violating phases beyond the Kobayashi–Maskawa phase of the SM. These phases appear in complex soft SUSY-breaking mass parameters of sfermions and gauginos and in complex trilinear Yukawa couplings. They have a wealth of phenomenological implications. In particular, they give rise to signatures of CP violation in sparticle production and decay at high-energy colliders [16–18], have observable effects on electric dipole moments (EDMs) [19–21] and $B$-meson decays [22, 23], and might constitute the extra ingredients needed for electroweak baryogenesis [24].

In this paper we study resonant CP-violating phenomena in the Higgsstrahlung mechanism for producing neutral MSSM Higgs bosons at a high-energy $e^+e^−$ linear collider. Although our study is performed within the radiative CP-violating framework of the MSSM [5–9,25–28], the results of our analysis would also be applicable to more general CP-violating two-Higgs-doublet models [29] in which all three neutral Higgs bosons mix strongly. This work extends previous studies of the masses, couplings, production and
decays of the mixed-CP neutral Higgs bosons $H_{1,2,3}$, with a view to searches at LEP [10], the LHC [10,11,15,30–34], the ILC [35], a $\mu^+\mu^-$ collider [36] and a Photon Linear Collider (PLC) [14,37–40]. As in our previous works [13–15], we present a complete treatment of loop-induced CP violation and Higgs tri-mixing, including off-diagonal absorptive effects in the resummed Higgs-boson propagator matrix [12]. Complementary to the previous studies at the ILC [35], our focus here is on analyzing the production lineshape of a coupled system of neutral Higgs bosons in the Higgsstrahlung process, as well as the construction of feasible CP asymmetries which could be probed experimentally.

Higgs-boson production via the Higgsstrahlung process $e^+e^- \rightarrow H_i Z$ [1], where the $Z$ boson decays into electron or muon pairs, offers a unique environment for determining the masses and widths of the neutral Higgs bosons by the recoil-mass method [41,42]. Thanks to the excellent energy and momentum resolution of electrons and muons coming from the $Z$-boson decay, the recoil mass against the $Z$ boson, $p^2 = s - 2 \cdot \sqrt{s} \cdot E_Z + M_Z^2$, can be reconstructed with a precision as good as 1 GeV. Here $s$ and $E_Z$ are the the collider centre-of-mass energy squared and the energy of the $Z$ boson, respectively.

As mentioned above, our focus is on the CP-violating tri-mixing scenario of the MSSM, in which all three neutral Higgs bosons have similar masses and mix strongly with each other. In particular, we examine the production lineshape of the coupled system of neutral Higgs bosons in this tri-mixing scenario. The lineshape for $H_{1,2,3} \rightarrow \bar{b}b$ decays is sensitive to the CP-violating parameters of the model. Moreover, employing the longitudinal and transverse polarizations of the tau leptons coming from the decays of Higgs bosons, we can measure CP asymmetries which can be as large as 80%, without violating EDM constraints.

The layout of the paper is as follows. In Section 2, we study the Higgsstrahlung process at an $e^+e^-$ collider and the subsequent Higgs-boson decays, $H_i \rightarrow f \bar{f}$ with $f = b$ and $\tau^-$. We define the individual cross sections that depend on the longitudinal and transverse polarizations of the final fermions. In Section 3, we consider the constraints from the non-observation of an EDM in the Thallium atom on the relevant CP phases in the tri-mixing scenario. In Section 4, we construct two CP asymmetries and present numerical examples for the two final states $f \bar{f} = b\bar{b}$ and $\tau^-\tau^+$. Our conclusions are given in Section 5.
\[ e^-(p_1, \omega) \rightarrow Z^*(\sqrt{s}) \rightarrow H_i Z \rightarrow [f(\sigma)\bar{f}(\bar{\sigma})] Z. \]

Figure 1: The dominant mechanism contributing to the process \( e^+ e^- \rightarrow H_i Z \rightarrow [f(\sigma)\bar{f}(\bar{\sigma})] Z \).

2 The Process \( e^+ e^- \rightarrow H_i Z \rightarrow [f(\sigma)\bar{f}(\bar{\sigma})] Z \)

The general helicity amplitude for the process \( e^- (p_1, \omega) e^+ (p_2, \bar{\omega}) \rightarrow H_i (p) Z(k, \lambda) \rightarrow [f(l_1, \sigma)\bar{f}(l_2, \bar{\sigma})] Z(k, \lambda) \), depicted in Fig. 1, may be written as

\[ M^\lambda_\sigma_\omega = \frac{-g^2 g_f M_W^2}{c_W^2 \sqrt{s} \sqrt{p^2}} D_Z(s)(\omega; \lambda)_\Theta \left( \sum_{i,j} (\sigma^f_{ij}) \right) \delta_{\omega - \bar{\omega}} \delta_{\sigma \bar{\sigma}}. \tag{1} \]

The four-momenta and helicities of the initial electron and positron are denoted by \((p_1, \omega)\) and \((p_2, \bar{\omega})\), respectively, and \(s \equiv (p_1 + p_2)^2\). We denote the helicities of \( f \) and \( \bar{f} \) by \( \sigma \) and \( \bar{\sigma} \), and that of the \( Z \) boson by \( \lambda \). Also, \( \sigma = +(-) \) stands for a right- (left)-handed particle and \( \lambda = \pm \) and \( \lambda = 0 \) for the transverse (right and left helicities) and longitudinal polarizations, respectively. The four-momentum of the intermediate Higgs boson is denoted by \( p \) and those of the final fermions by \( l_1 \) and \( l_2 \) with \( p = l_1 + l_2 \). Finally, \( \Theta \) is the angle between \( p_1 \) and \( k \) where the four-momentum of the \( Z \) boson is \( k = (E_Z, k) \).

In (1), \( D_Z(s) \) is the \( s \)-normalized Breit–Wigner propagator for the \( Z \) boson:

\[ D_Z(s) = \frac{s}{s - M_Z^2 + iM_Z \Gamma_Z}, \tag{2} \]

and \( (\omega; \lambda)_\Theta \) and \( (\sigma^f_{ij}) \) describe the reduced amplitudes

\[ (\omega; \lambda = 0)_\Theta = -(v_e + \omega a_e) \frac{\omega E_Z}{M_Z} s_\Theta, \quad (\omega; \lambda = \pm)_\Theta = (v_e + \omega a_e) \frac{1 + \omega \lambda c_\Theta}{\sqrt{2}}, \]

\[ (\sigma^f_{ij}) = g_{HI_{ij}} \bar{V} D_{ij}(p^2)(\sigma^\beta g_{HI,ff} - ig_{HI,ff}^P), \tag{3} \]

where \( s_\Theta \equiv \sin \Theta, c_\Theta \equiv \cos \Theta \) and \( v_e = -1/4 + s_W^2 \) and \( a_e = 1/4 \). This result is consistent with the one given in [43,44]. For the definitions of the couplings, the threshold corrections
that are enhanced for large values of $\tan \beta$ for $f = b, \tau$, and the full $3 \times 3$ propagator matrix $D_{ij}(p^2)$, we refer to [13, 45].

The differential cross-section, after integrating over $c_\Theta$, is given by

$$p^2 \frac{d\sigma}{dp^2} = \sigma_{H^Z}^{SM}(p^2) \times \frac{N_f g_f^2 \beta_f(p^2)}{16\pi^2} \left\{ (1 + P_L \bar{P}_L) C_1^f(p^2) + (P_L + \bar{P}_L) C_2^f(p^2) + P_T \bar{P}_T \left[ \cos(\alpha - \bar{\alpha}) C_3^f(p^2) + \sin(\alpha - \bar{\alpha}) C_4^f(p^2) \right] \right\},$$

(4)

where $N_f$ is the color factor of the final-state fermion: $N_f = 3$ for the $b$ quark and 1 for the $\tau$ lepton, $\beta_f(p^2) \equiv \sqrt{1 - 4m_f^2/p^2}$. Moreover, $\sigma_{H^Z}^{SM}(p^2)$ is the SM cross section for the Higgsstrahlung of an off-shell Higgs boson with mass $\sqrt{p^2}$, i.e.,

$$\sigma_{H^Z}^{SM}(p^2) = \frac{g^4(v_e^2 + a_e^2) \lambda^{1/2}(p^2)[\lambda(p^2) + 12M_Z^2/s]}{192\pi c_W^2 s} \left( 1 - \frac{M_Z^2}{s} \right)^2 + \frac{M_Z^2 \Gamma_Z^2}{s^2} ,$$

(5)

where $\lambda(p^2) = (1 - p^2/s - M_Z^2/s)^2 - 4p^2M_Z^2/s^2$ is a kinematic phase-space function. Then, with the definition

$$\langle \sigma \rangle_f = \sum_{i,j} \langle \sigma \rangle_{ij}^f,$$

(6)

the polarization coefficients $C_i^f$ may conveniently be expressed as follows:

$$C_1^f(p^2) = \frac{1}{4} \left( \langle + \rangle |^2 + \langle - \rangle |^2 \right), \quad C_2^f(p^2) = \frac{1}{4} \left( \langle + \rangle |^2 - \langle - \rangle |^2 \right), \quad C_3^f(p^2) = -\frac{1}{2} \Re \left( \langle + \rangle \langle - \rangle^* \right), \quad C_4^f(p^2) = \frac{1}{2} \Im \left( \langle + \rangle \langle - \rangle^* \right).$$

(7)

In (4), $P_L$ and $\bar{P}_L$ are the longitudinal polarizations of the final fermion $f$ and antifermion $\bar{f}$, respectively, whereas $P_T$ and $\bar{P}_T$ are the degrees of transverse polarization, with $\alpha$ and $\bar{\alpha}$ being the azimuthal angles with respect to the $f$-$\bar{f}$ production plane. We depict in Fig. 2 the production plane in the Higgs-boson rest frame in the case when $f = \tau^-$ and the $\tau$ leptons decay into charged hadrons $h^\pm$ and neutrinos, $\tau^\pm \rightarrow h^\pm \nu_\tau (\bar{\nu}_\tau)$ with $h^\pm = \pi^\pm, \rho^\pm$, etc.

Identifying the polarization analyser for $\tau^+$ as

$$\hat{a}^\tau = \pm \hat{h}^\tau,$$

(8)

where $\hat{h}^\tau$ denote unit vectors parallel to the $h^\tau$ momenta in the $\tau^\tau$ rest frame, we have

$$P_L = \cos \theta^-, \quad P_T = \sin \theta^-, \quad \alpha = \varphi^-; \quad \bar{P}_L = \cos \theta^+, \quad \bar{P}_T = \sin \theta^+, \quad \bar{\alpha} = \varphi^+ - \pi,$$

(9)

where $\theta^\pm$ and $\varphi^\pm$ are the polar and azimuthal angles of $h^\pm$, respectively, in the $\tau^\pm$ rest frame. With this identification, the expression in the curly brackets of (4) becomes

$$\left(1 + P_L \bar{P}_L\right) C_1^f(p^2) + (P_L + \bar{P}_L) C_2^f(p^2) + P_T \bar{P}_T \left[ \cos(\alpha - \bar{\alpha}) C_3^f(p^2) + \sin(\alpha - \bar{\alpha}) C_4^f(p^2) \right]$$

$$= \left(1 + \cos \theta^+ \cos \theta^- \right) C_1^f(p^2) + (\cos \theta^- + \cos \theta^+) C_2^f(p^2)$$

$$- \sin \theta^+ \sin \theta^- \left[ \cos(\varphi^- - \varphi^+) C_3^f(p^2) + \sin(\varphi^- - \varphi^+) C_4^f(p^2) \right].$$

(10)
Figure 2: The $\tau^+\tau^-$ production plane in the Higgs-boson rest frame, in the case when the $\tau$ leptons decay into hadrons $h^\pm$ and neutrinos. The longitudinal-polarization vector $P_L(\bar{P}_L)$ and the transverse-polarization vector $P_T(\bar{P}_T)$ with the azimuthal angle $\alpha(\bar{\alpha})$ of $\tau^-(\tau^+)$ are shown.

We observe that the polarization coefficients $C_i^r(p^2)$ can be determined by examining the angular distributions of the charged hadrons coming from the $\tau$-lepton decays; $\tau^\pm \to h^\pm \nu(\bar{\nu})$ [46].

Finally, for our phenomenological discussion in Section 4, it proves more convenient to define the individual cross sections:

$$\hat{\sigma}^f_i(p^2) \equiv \sigma_{HZ}(p^2) \frac{N_f g_i^2 \beta_i(p^2)}{16\pi^2} C_i^f(p^2). \quad (11)$$

3 The Tri-mixing Scenario and the Thallium EDM

We take the following parameter set for numerical examples in Section 4:

$$\tan \beta = 50, \quad M_{H^\pm}^\text{pole} = 155 \ \text{GeV},$$

$$M_{Q_3} = M_{U_3} = M_{D_3} = M_{L_3} = M_{E_3} = M_{\text{SUSY}} = 0.5 \ \text{TeV},$$

$$|\mu| = 0.5 \ \text{TeV}, \quad |A_{t,b,\tau}| = 1 \ \text{TeV}, \quad |M_2| = |M_1| = 0.3 \ \text{TeV}, \quad |M_3| = 1 \ \text{TeV},$$

$$\Phi_{\mu} = 0^\circ, \quad \Phi_1 = \Phi_2 = 0^\circ. \quad (12)$$

We refer to this scenario as the tri-mixing scenario, since the mass differences between three neutral Higgs bosons are comparable to the decay widths and all the three Higgs bosons mix significantly in the presence of non-vanishing CP phases. In this scenario, the common

*In Refs. [46], the CP- and CPT-odd $C_2^f(p^2)$ coefficient is missing since only one Higgs state was considered.
third generation phase $\Phi_A = \Phi_{A_t} = \Phi_{A_b} = \Phi_{A_{\tau}}$ and that of the gluino mass parameter $\Phi_3$ are free parameters, which are constrained by the non-observation of EDMs of atoms, molecules, and the neutron [21]. The contributions of the first and second generation phases, e.g. $\Phi_{A_{e,\mu}}$, $\Phi_{A_{d,s}}$ etc., to EDMs can be drastically reduced either by making these phases sufficiently small, or if the first- and second-generation squarks and sleptons are sufficiently heavy. The impact of these phases on the Higgs sector is negligible.

The EDM of the Thallium atom currently provides the best constraint on the MSSM scenarios of our interest. The atomic EDM of $^{205}\text{Tl}$ get main contributions from two terms [47, 48]:

$$d_{\text{Tl}}[e\text{ cm}] = -585 \cdot d_e[e\text{ cm}] - 8.5 \times 10^{-19}[e\text{ cm}] \cdot (C_S \text{ TeV}^2) + \cdots,$$

where $d_e$ denotes the electron EDM and $C_S$ is the coefficient of a CP-odd electron-nucleon interaction $\mathcal{L}_{C_S} = C_S \bar{e} i \gamma_5 e \bar{N} N$. The dots denote sub-dominant contributions from 6-dimensional tensor and higher-dimensional operators. The experimental $2 - \sigma$ bound on the Thallium EDM is [50]:

$$|d_{\text{Tl}}| \lesssim 1.3 \times 10^{-24}[e\text{ cm}].$$

In the CPsuperH [45] conventions and notations, the coefficient $C_S$ is given by

$$C_S = -(0.1 \text{ GeV}) \tan \beta \frac{m_e \pi \alpha_{\text{em}}}{s_W^2 M_W^2} \sum_{i=1}^3 \frac{g_{H_{i,gg} O_{ai}}}{M_{H_i}^2},$$

where

$$g_{H_{i,gg}} = \sum_{q=t,b} \left\{ \frac{2}{3} g_{H_{i,qq}}^S - \frac{v^2}{12} \sum_{j=1,2} \frac{g_{H_{i,\tilde{q}_j \tilde{q}_j}}^S}{m_{\tilde{q}_j}^2} \right\}.$$

The Higgs-boson two-loop contributions to the electron EDM $d_e$ are [51]:

$$\left( \frac{d_e}{e} \right)^\tilde{q} = \frac{3 \alpha_{\text{em}} Q_q m_e}{32 \pi^3} \sum_{i=1}^3 \frac{g_{H_{i,e+e-}}^P}{M_{H_i}^2} \sum_{j=1,2} g_{H_{i,\tilde{q}_j \tilde{q}_j}} F(\tau_{\tilde{q}_j i}),$$

$$\left( \frac{d_e}{e} \right)^q = -\frac{3 \alpha_{\text{em}} Q_q m_e}{8 \pi^2 s_W^2 M_W^2} \sum_{i=1}^3 \left[ g_{H_{i,e+e-}}^S g_{H_{i,\tilde{q} \tilde{q}}}^S f(\tau_{\tilde{q} \tilde{q}}) + g_{H_{i,e+e-}}^S g_{H_{i,\tilde{q} \tilde{q}}}^S g(\tau_{\tilde{q} \tilde{q}}) \right],$$

$$\left( \frac{d_e}{e} \right)^{\chi^\pm} = -\frac{\alpha_{\text{em}} m_e}{4 \sqrt{2} \pi^2 s_W^2 M_W} \times \sum_{i=1}^3 \sum_{j=1,2} \frac{1}{m_{\chi_j^\pm}} \left[ g_{H_{i,e+e-}}^S g_{H_{i,\chi_j^\pm}}^S f(\tau_{\chi_j^\pm}) + g_{H_{i,e+e-}}^S g_{H_{i,\chi_j^\pm}}^S g(\tau_{\chi_j^\pm}) \right].$$

\footnote{Our sign convention for $C_S$ follows the one given in [48, 49].}
with \( q = t, b \) and \( \tau x_i = m^2_{x_i}/M^2_{H_i} \). The total Higgs-mediated two-loop \((d_e/e)^H\) is given by the sum

\[
\left(\frac{d_e}{e}\right)^H = \left(\frac{d_e}{e}\right)^t + \left(\frac{d_e}{e}\right)^b + \left(\frac{d_e}{e}\right)^q + \left(\frac{d_e}{e}\right)^\tau + \ldots,
\]

and the two-loop functions \( F(\tau), f(\tau), \) and \( g(\tau) \) may be found in Ref. [51]. The ellipses in (18) denote other sub-dominant two-loop contributions to EDM that involve charged Higgs and Higgsino effects [52].

We note that \( C_S \) in (15) and \((d_e/e)^H\) in (18) are calculated at the electroweak (EW) scale, where the responsible effective interactions are generated. In order to calculate the running from the EW scale to the appropriate low-energy scale, the anomalous dimension (matrix) should be considered. We neglect this effect by observing that it can be absorbed in the evaluation of the matrix element

\[
\langle N|\frac{\alpha S}{8\pi}G^{a,\mu\nu}G^{a}_{\mu\nu}|N \rangle = -(0.1) \text{ GeV} \bar{N}N,
\]

which gives (15). We use \( \alpha_{em} = 1/137 \).

In Fig. 3, we show the rescaled Thallium EDM \( \hat{d}_{Tl} \equiv d_{Tl} \times 10^{24} \) in units of e cm in the \( \Phi_A-\Phi_3 \) plane (upper left) and as a function of \( \Phi_A (\Phi_3) \) for several values of \( \Phi_3 (\Phi_A) \) in the upper-right (lower-left) frame. The lower-right frame shows the individual contributions as functions of \( \Phi_3 \) when \( \Phi_A = 60^\circ \). We consider contributions from the Higgs-mediated two-loop \((d_e/e)^H\) and \( C_S \), not including other contributions. In the upper-left frame, different ranges of \( |\hat{d}_{Tl}| \) are shown explicitly by different shadings. The blank unshaded region around the point \( \Phi_3 = \Phi_A = 180^\circ \) is not theoretically allowed since there large threshold corrections to the bottom-quark Yukawa coupling \( h_b \) result in a tachyonic sbottom, a complex or negative Higgs mass, a non-perturbative value of the Yukawa coupling \(|h_b| > 2\), and/or a failure of the iteration method of calculating the corrections. We note that, in the region \( |\hat{d}_{Tl}| < 10 \), the Thallium EDM constraint can be evaded by assuming cancellations of less than 1 part in 10 between the two-loop contributions considered here and possible one-loop contributions not discussed here. As mentioned above, such cancellations are always possible in a general unconstrained MSSM scenario, where one-loop EDM effects depend on different CP-odd phases related to the first and second generations of squarks and sleptons. In our case, cancellations between the contributions from \((d_e/e)^H\) and \( C_S \) are shown in Fig. 3 as dips for specific values of \( \Phi_A \) and \( \Phi_3 \) in the upper-right and lower-left frames. These are responsible for the narrow region filled with black squares in the upper-left frame in which \( |\hat{d}_{Tl}| < 1 e \text{cm} \). For example, the lower-right frame clearly shows the cancellation between the contributions from \((d_e/e)^{t,\tilde{t}}\) and \( C_S \) when \( \Phi_3 \sim 220^\circ \) and \( 280^\circ \) for \( \Phi_A = 60^\circ \), see also the dotted line in the lower-left frame.
In the CP-violating tri-mixing scenarios of the MSSM, the flavour-changing neutral current couplings of the Higgs bosons $H_{1,2,3}$ to down-type quarks are considerably enhanced at large values of $\tan \beta$ [22, 53], i.e. for $\tan \beta \gtrsim 40$. These $\tan \beta$-enhanced Higgs couplings can give rise to potentially important constraints on the parameters of the CP-
violating MSSM, which arise from the non-observation of the Higgs-mediated $B$-meson decay $B_{s,d} \rightarrow \mu \mu$ at the Tevatron [54]. However, according to a detailed study [23], the derived constraints are highly dependent on detailed aspects of flavour physics, and may be relaxed dramatically for certain choices of the soft supersymmetry-breaking mass spectrum that cause cancellations in the unitarity sum over quark flavours. In view of these and other theoretical uncertainties [55], $B_{s,d} \rightarrow \mu \mu$ decays do not yet impose significant constraints on the parameter space relevant to this study.

4 Numerical Examples

For numerical studies, we take $\sqrt{s} = 300$ GeV and consider four different combinations of CP phases of $(\Phi_3, \Phi_A)$ in the tri-mixing scenario (12) that are chosen to respect the Thallium EDM constraint:

\begin{align*}
\text{P0} & : (\Phi_3, \Phi_A) = (0^\circ, 0^\circ) : \\
& (M_{H_1}, M_{H_2}, M_{H_3}; \Gamma_{H_1}, \Gamma_{H_2}, \Gamma_{H_3}) = (119.2, 123.7, 125.6; 1.42, 2.95, 1.50) \text{ GeV}, \\
\text{P1} & : (\Phi_3, \Phi_A) = (-55^\circ, 30^\circ) : \\
& (M_{H_1}, M_{H_2}, M_{H_3}; \Gamma_{H_1}, \Gamma_{H_2}, \Gamma_{H_3}) = (118.9, 122.9, 124.6; 1.57, 3.45, 2.60) \text{ GeV}, \\
\text{P2} & : (\Phi_3, \Phi_A) = (-80^\circ, 60^\circ) : \\
& (M_{H_1}, M_{H_2}, M_{H_3}; \Gamma_{H_1}, \Gamma_{H_2}, \Gamma_{H_3}) = (118.6, 121.1, 123.5; 2.17, 4.77, 4.45) \text{ GeV}, \\
\text{P3} & : (\Phi_3, \Phi_A) = (-80^\circ, 90^\circ) : \\
& (M_{H_1}, M_{H_2}, M_{H_3}; \Gamma_{H_1}, \Gamma_{H_2}, \Gamma_{H_3}) = (119.0, 119.5, 122.9; 2.57, 5.70, 5.63) \text{ GeV},
\end{align*}

(20)

where the masses and widths of the neutral Higgs bosons are calculated using CPsuperH [45]. We observe that the three neutral Higgs bosons are almost degenerate with masses around 120 GeV, and large widths comparable to the mass differences. At the CP-conserving point P0, the second lightest Higgs boson $H_2$ is CP odd and the CP-even $H_1$ and $H_3$ have strong two-way mixing. But, in the presence of non-vanishing CP phases, as at points P1, P2 and P3, all the three neutral Higgs bosons mix significantly. The three CP-violating points P1, P2 and P3 are chosen to lie along the narrow region filled with black squares in the upper-left panel of Fig. 3 where the two contributions from $(d_e/e)^H$ and $C_S$ to the Thallium EDM cancel approximately and we have $|\hat{d}_{Tl}| < 1$ e cm. Thus, this selection of points complements the information available from low-energy EDM experiments.
4.1 Backgrounds

We consider the two final states $f = b$ and $f = \tau^-$ for the Higgs-boson decays. Therefore, before showing the numerical results for the Higgsstrahlung processes, we first consider the SM background processes $e^+e^- \rightarrow f\bar{f}Z$ with $f = b$ and $\tau^-$, omitting the Higgs-mediated diagrams, as seen in Fig. 4. The background cross sections are evaluated using CompHEP [56].

We show in Fig. 5 the product of the differential background cross section $d\sigma_{bkg}/d\sqrt{p^2}$ and the branching fraction of the $Z$ boson into electrons and muons, $B(Z \rightarrow l^+l^-)$, as a function of the invariant mass of the fermion-antifermion pair $\sqrt{p^2}$ in units of fb/GeV. The solid line is for $f = b$ and the dashed line for $f = \tau^-$. We used for the leptonic branching fraction [57]:

$$B(Z \rightarrow l^+l^-) = B(Z \rightarrow e^+e^-) + B(Z \rightarrow \mu^+\mu^-) = 6.73 \times 10^{-2}.$$ (21)

We note that the product of the background cross section and the branching fraction of the $Z$ boson into light leptons is smaller than $\sim 0.03 (0.01)$ fb/GeV for $f = b (\tau^-)$ when $\sqrt{p^2} > 110$ GeV.

Figure 4: Diagrams for the SM background process $e^+e^- \rightarrow f\bar{f}Z$ with $f = b$ and $\tau^-$. 

---

11
Figure 5: The product of the differential background cross section and the branching fraction of the $Z$ boson into electrons and muons, $\frac{d\sigma_{bkg}}{d\sqrt{p^2}} \times B(Z \rightarrow l^+l^-)$, as a function of $\sqrt{p^2}$ in units of fb/GeV. The solid line is for the process $e^+e^- \rightarrow b\bar{b}Z$ and the dashed line for $e^+e^- \rightarrow \tau^+\tau^-Z$.

### 4.2 CP-Conserving Cross Sections

The differential total cross section can be obtained by summing over the polarizations $P$ and $\bar{P}$ in (4). We have

$$\frac{d\sigma_{tot}^f}{d\sqrt{p^2}} = \frac{8}{\sqrt{p^2}} \hat{\sigma}_1^f(p^2),$$

(22)

where $\hat{\sigma}_1^f$ is defined as in (11). We show in Fig. 6 the differential total cross section multiplied by $B(Z \rightarrow l^+l^-)$ when the produced Higgs bosons decay into $b$ quarks: $\frac{d\sigma_{tot}^b}{d\sqrt{p^2}} \times B(Z \rightarrow l^+l^-)$. The cross sections are significantly larger (0.1-5 fb/GeV) than that of the SM background (< 0.02 fb/GeV) around the peaks. In the CP-conserving case $P0$, we clearly see two peaks of the CP-even Higgs bosons at $\sqrt{p^2} = 119.2$ GeV ($H_1$) and at
\[ \sqrt{p^2} = 125.6 \text{ GeV} \ (H_3), \] see also (20). The second lightest CP-odd \( H_2 \) does not contribute. However, in the CP-violating cases this two-peak structure becomes less clear as the phase \( \Phi_A \) increases: see the dashed (\( P_1 : \Phi_A = 30^\circ \)), dotted (\( P_2 : \Phi_A = 60^\circ \)), and dashed-dotted (\( P_3 : \Phi_A = 90^\circ \)) lines. The disappearance of the two-peak structure is the combined effect of increasing (decreasing) \( H_2 \) (\( H_3 \)) coupling to \( Z \) bosons, \( g_{H_2VV}^2 \) (\( g_{H_3VV}^2 \)), and decreasing mass difference between \( H_1 \) and \( H_2 \) without visible changes in \( M_{H_1} \) around 119 GeV. The sensitivity of this CP-conserving quantity to the CP-violating phases will be measurable by examining the production lineshape at the ILC. For example, an integrated luminosity larger than \( \sim 100 \text{ fb}^{-1} \) would enable a difference of \( \sim 0.1 \text{ fb/GeV} \) in cross sections to be distinguished easily.

As was emphasized in [13], the resonance lineshape of a coupled system of neutral Higgs bosons is not a process-independent quantity, but crucially depends on its production and decay channels. A combined analysis of the different production and decay channels at the LHC, ILC and PLC can shed light on whether one is dealing with a single, two- or multi-component system of Higgs bosons. Such an extensive analysis is beyond the scope of the present paper and may be given elsewhere. As we demonstrate explicitly below, the possible observation of non-zero CP asymmetries could give further insight into the CP composition of such a resonant Higgs boson system \(^\dagger\).

When the produced Higgs bosons decay into \( \tau \) leptons, we can construct another CP-conserving cross section in addition to the total cross section, by measuring the transverse polarizations of tau leptons or, equivalently, by examining the polar and azimuthal angle distributions of the charged hadrons coming from the \( \tau \)-lepton decays:

\[
\frac{d\sigma_\tau^T}{d\sqrt{p^2}} = \frac{8 \hat{\sigma}_3^T(p^2)}{\sqrt{p^2}}. \tag{23}
\]

This is related to the polarization coefficient \( C_3^T(p^2) \) in (4) and (10). The CP-conserving total and transverse differential cross sections multiplied by \( B(Z \to l^+l^-) \) are shown in the left and right panels of Fig. 7, respectively. The cross sections are smaller than that of the \( b \)-quark case (\( \sim 0.01\text{–}1 \text{ fb/GeV} \)), but the transverse cross section \( d\sigma_\tau^T/d\sqrt{p^2} \) provides extra sensitivity to the CP-violating phases in the \( \tau \)-lepton case, in addition to the total cross section.

\(^\dagger\)We should note that performing an overall fit to the production lineshape becomes more challenging in the presence of CP violation. Specifically, one has three masses of neutral Higgs bosons, six widths including off-diagonal absorptive effects, and two independent Higgs-boson couplings to \( Z \) bosons. Therefore, the analysis of other observables in addition to the total cross section would be very useful for the complete determination of the parameters.
Figure 6: The differential total cross section multiplied by $B(Z \rightarrow l^+ l^-)$ when the produced Higgs bosons decay into $b$ quarks: $\frac{d\sigma^{b}_{\text{tot}}}{d\sqrt{p^2}} \times B(Z \rightarrow l^+ l^-)$. The CP-conserving two-way mixing ($P0$) and the CP-violating tri-mixing ($P1$-$P3$) scenarios have been taken, see (12) and (20). The solid line is for $P0$, the dashed line for $P1$, the dotted line for $P2$, and the dash-dotted line for $P3$. The SM background cross section from Fig. 5 is also shown.

4.3 CP-Violating Cross Sections and Asymmetries

When the produced Higgs bosons decay into $\tau$ leptons, there are two CP-violating cross sections which are defined using the longitudinal and transverse polarizations of $\tau$ leptons:

$$\frac{d\Delta\sigma^L_\tau}{d\sqrt{p^2}} = \frac{8}{\sqrt{p^2}} \sigma^L_\tau(p^2), \quad \frac{d\Delta\sigma^T_\tau}{d\sqrt{p^2}} = \frac{8}{\sqrt{p^2}} \sigma^T_\tau(p^2),$$

(24)

where $\Delta\sigma^L_\tau$ and $\Delta\sigma^T_\tau$ are related to the polarization coefficients $C^L_2(p^2)$ and $C^I_4(p^2)$, respectively. The polarization coefficients $C^L_2(p^2)$ and $C^I_4(p^2)$ can be determined by measuring the longitudinal and transverse polarizations of $\tau$ leptons, respectively [cf. (4) and (10)].
Figure 7: Two differential CP-conserving cross sections (multiplied by $B(Z \rightarrow l^+l^-)$) that are observable when the produced Higgs bosons decay into $\tau$ leptons: $\frac{d\sigma\tau}{d\sqrt{p^2}} \times B(Z \rightarrow l^+l^-)$ (left panel) and $\frac{d\sigma\tau}{d\sqrt{p^2}} \times B(Z \rightarrow l^+l^-)$ (right panel). The line styles are as in Fig. 6.

We define the corresponding longitudinal and transverse CP asymmetries as follows:

$$a^L_{\tau}(p^2) \equiv \frac{d\Delta\sigma^L_{\tau}}{d\sigma^L_{\tau}} / \frac{d\sigma^L_{\tau} / d\sqrt{p^2}} = \frac{\sigma^L_{\tau}(p^2)}{\sigma^L_1(p^2)}, \quad a^T_{\tau}(p^2) \equiv \frac{d\Delta\sigma^T_{\tau}}{d\sigma^T_{\tau}} / \frac{d\sigma^T_{\tau} / d\sqrt{p^2}} = \frac{\sigma^T_{\tau}(p^2)}{\sigma^T_1(p^2)}.$$ (25)

We show in Fig. 8 the CP-violating cross sections (left column) and CP asymmetries (right column). The CP-violating cross sections are large enough to be measured, assuming luminosity of $> 100 \text{ fb}^{-1}$, for each choice of the CP-violating phases, and the CP asymmetry can be as large as 80%. Analysis of the production lineshape would enable the cases with different CP-violating phases to be distinguished from each other. Since the CP-violating scenarios chosen respect the low-energy EDM constraints, these examples show that linear-collider measurements are complementary, and large CP-violating effects cannot be excluded a priori.

5 Conclusions

We have shown that the Higgsstrahlung process $e^+e^- \rightarrow H_{1,2,3}(Z \rightarrow e^+e^-), \mu^+\mu^-$, with subsequent decays $H_{1,2,3} \rightarrow b\bar{b}$, $\tau^-\tau^+$ is potentially a useful channel of searching for radiative Higgs-sector CP violation in the MSSM. The recoil-mass method would enable one to measure the invariant mass of a $b\bar{b}$ or $\tau^-\tau^+$ pair produced in Higgs decay with a precision as good as 1 GeV. In tri-mixing scenarios where all three neutral Higgs states of the MSSM
are nearly degenerate and mix significantly, this accuracy would enable details of complicated lineshapes to be disentangled. An integrated luminosity of 100 fb$^{-1}$ would already be sufficient to measure CP-violating parameters via their influences on the production lineshape of a coupled system of neutral Higgs bosons decaying into $b\bar{b}$ quarks. Measurements of the Higgs bosons decaying into $\tau^+\tau^-$ would enable an additional CP-conserving cross section and two CP-violating asymmetries to be defined in terms of the longitudinal and transverse polarizations of the $\tau$ leptons.

We find that these CP asymmetries could be as large as 80%, even after taking into account the constraints from the Thallium electric dipole moment, and different CP-violating models compatible with the Thallium data could be distinguished. Thus, measurements of

Figure 8: Two differential CP-violating cross sections (multiplied by $B(Z \to l^+l^-)$) observable when the produced Higgs bosons decay into $\tau$ leptons: $\frac{d\Delta\sigma^\tau}{d\sqrt{p^2}} \times B(Z \to l^+l^-)$ (upper-left panel) and $\frac{d\Delta\sigma^\tau}{d\sqrt{p^2}} \times B(Z \to l^+l^-)$ (lower-left panel). The two corresponding CP-violating asymmetries are shown in the right column: $a_L^\tau$ (upper-right panel) and $a_T^\tau$ (lower-right panel). The lines styles are the same as in Fig. 6.
CP violation in Higgsstrahlung at an $e^+e^-$ linear collider would complement high-precision low-energy measurements, and might provide a signal, even if none is visible in the low-energy experiments.

Finally, we should stress that the analysis presented in this paper is general and applies equally well to extended CP-violating Higgs sectors with similar phenomenological features. CP violation and its relation to the cosmological baryon asymmetry are among the outstanding questions in possible physics beyond the Standard Model, and measurements of the Higgsstrahlung process could provide a unique window that could shine valuable light on attempts to relate these two puzzles.
