Infinitesimal projective rigidity under Dehn filling

Michael Heusener and Joan Porti

June 3, 2010

Abstract

To a hyperbolic manifold one can associate a canonical projective structure and a fundamental question is whether or not it can be deformed. In particular, the canonical projective structure of a finite volume hyperbolic manifold with cusps might have deformations which are trivial on the cusps.

The aim of this article is to prove that if the canonical projective structure on a cusped hyperbolic manifold \( M \) is infinitesimally projectively rigid relative to the cusps, then infinitely many hyperbolic Dehn fillings on \( M \) are locally projectively rigid. We analyze in more detail the figure eight knot and the Whitehead link exteriors, for which we can give explicit infinite families of slopes with projectively rigid Dehn fillings.

MSC: 57M50; 53A20; 53C15

Keywords: Projective structures; variety of representations; infinitesimal deformations.

1 Introduction

A closed hyperbolic \( n \)-dimensional manifold inherits a canonical projective structure. This can be easily seen by considering the Klein model for the hyperbolic space. Projective structures on manifolds were studied by Benzécri in the 1960’s. Though the hyperbolic structure is rigid for \( n > 2 \) (cf. [31] [24]), it might be possible to deform the canonical projective structure. Kac and Vinberg [20] gave the first examples of such deformations. Koszul [20] and Goldman later generalized these examples. Johnson and Millson provide deformations of the canonical projective structure by means of bending along totally geodesic surfaces [17]. Examples of deformations for Coxeter orbifolds have been obtained by Choi [8] and Marquis [23].

In the sequel we will use the following notation:

*Partially supported by the Spanish Micinn through grant MTM2009-07594. Prize ICREA 2008
1.1 Definition A closed hyperbolic manifold is called *locally projectively rigid* if the canonical projective structure induced by the hyperbolic metric cannot be deformed.

Cooper, Long and Thistlethwaite have studied the deformability of 4500 hyperbolic manifolds from the Hodgson-Weeks census with rank 2 fundamental group \[9\], proving that at most 61 can be deformed. The goal of this paper is to provide infinite families of projectively locally rigid manifolds, by means of Dehn filling.

Let \( N \) be a closed hyperbolic 3-dimensional manifold. We will make use of the fact that geometric structures on \( N \) are controlled by their holonomy representation. Hence we consider the holonomy representation of the closed hyperbolic 3-manifold \( \rho: \pi_1(N) \rightarrow P\text{SO}(3,1) \subset P\text{GL}(4) \).

If not specified, the coefficients of matrix groups are real: \( P\text{GL}(4) = P\text{GL}(4,\mathbb{R}) \). The closed manifold \( N \) is locally projectively rigid if and only if all deformations of \( \rho \) in \( P\text{GL}(4) \) are contained in the \( P\text{GL}(4) \)-orbit of \( \rho \).

Existence or not of deformations is often studied at the infinitesimal level. We may consider the adjoint action on the lie algebra \( \mathfrak{so}(3,1) \). Then Weil’s infinitesimal rigidity \[31\] asserts that

\[
H^1(\pi_1(N); \mathfrak{so}(3,1)_{\text{Ad}} \rho) = 0.
\]

The adjoint action extends to the Lie algebra \( \mathfrak{sl}(4) := \mathfrak{sl}(4,\mathbb{R}) \) and motivates the following definition.

1.2 Definition A closed hyperbolic three manifold \( N \) is called *infinitesimally projectively rigid* if

\[
H^1(\pi_1(N); \mathfrak{sl}(4)_{\text{Ad}} \rho) = 0.
\]

Infinitesimal rigidity implies local rigidity, but the examples of \[10\] and \[9\] show that the converse is not true.

We are working with aspherical manifolds, so computing the cohomology of a manifold or of its fundamental group does not make any difference.

For cusped manifolds one has a similar definition. Let \( M \) denote a compact three manifold with boundary a union of tori and whose interior is hyperbolic with finite volume.

1.3 Definition The manifold \( M \) is called *infinitesimally projectively rigid* if the inclusion \( \partial M \subset M \) induces an injective homomorphism

\[
0 \rightarrow H^1(M; \mathfrak{sl}(4)_{\text{Ad}} \rho) \rightarrow H^1(\partial M; \mathfrak{sl}(4)_{\text{Ad}} \rho).
\]
The following theorem provides infinitely many examples of infinitesimally projectively rigid 3-dimensional manifolds.

1.4 Theorem Let $M$ be a compact orientable 3-manifold whose interior is hyperbolic with finite volume. If $M$ is infinitesimally projectively rigid, then infinitely many Dehn fillings on $M$ are infinitesimally projectively rigid.

A hyperbolic Dehn filling on $M$ induces a noncomplete structure on $M$, that can be viewed as a hyperbolic cone structure with cone angles $2\pi$. In some cases this cone angle can be decreased to zero, yielding the complete structure on $M$. The methods of Theorem 1.4 give the following:

1.5 Theorem Let $M$ be compact orientable 3-manifold whose interior is hyperbolic with cusps. If a Dehn filling on $M$ satisfies:

(i) it is infinitesimally projectively rigid,

(ii) the noncomplete induced structure on $M$ can be joined to the complete one by a path of hyperbolic cone structures parametrized by cone angle from $2\pi$ to 0,

then infinitely many Dehn fillings on $M$ are infinitesimally projectively rigid.

By Hodgson and Kerckhoff estimation of the size of the Dehn filling space [16], in a cusped manifold the deformation of Theorem 1.5 exists for all but at most 60 Dehn fillings. Hence:

1.6 Corollary Let $M$ be a one cusped hyperbolic manifold of finite volume. If 61 Dehn fillings on $M$ are either non-hyperbolic or infinitesimally projectively rigid, then infinitely many fillings are so.

Those results are proved using the fact that all parameters of Thurston’s hyperbolic Dehn filling space corresponding to non infinitesimally projectively rigid fillings on $M$ are contained in a proper analytic subset of the Dehn filling space, provided $M$ itself is infinitesimally projectively rigid. This technique goes back to Kapovich in the setting of deformations of lattices of $PSO(3,1)$ in $PSO(4,1)$ [18].

Moreover, we obtain explicit examples of infinite families of infinitesimally projectively rigid manifolds. The Dehn filling parameters of these families lie on certain real analytic curves, and a careful analysis of the infinitesimal deformations of the corresponding manifolds results in the following proposition:

1.7 Proposition For $n$ sufficiently large, the homology sphere obtained by $1/n$-Dehn filling on the figure eight knot is infinitesimally projectively rigid.

In fact, for every $k \in \mathbb{Z}$, $k \neq 0$, there exists $n_k > 0$ such that if $n \geq n_k$ then the $k/n$-Dehn filling on the figure eight knot is infinitesimally projectively rigid.
Theorem 1.4 provides infinitely many rigid Dehn fillings. One can ask whether there are still infinitely many non-rigid Dehn fillings. Though we do not have an example for manifolds, the following proposition shows that there are infinitely many non-rigid orbifolds obtained by Dehn fillings on the cusped manifold that satisfies the hypothesis of Theorem 1.4.

1.8 Proposition The orbifold $O_n$ with underlying space $S^3$, branching locus the figure eight knot and ramification index $n$ is not locally projectively rigid for sufficiently large $n$. More precisely, its deformation space is a curve.

For any $n \in \mathbb{N}$, the Fibonacci manifold $M_n$ is the cyclic cover of order $n$ of the orbifold $O_n$ in Proposition 1.8 [14]. Hence $M_n$ is not projectively rigid, as deformations of the projective structure of $O_n$ induce deformations of $M_n$. There is an abundant literature about those manifolds. For instance, $M_4$ is not Haken but $M_n$ is Haken for $n \geq 5$, and Scannell has proved that they are not infinitesimally rigid in $SO(4,1)$ [28].

Using that punctured torus bundles with tunnel number one are obtained by $n$-Dehn filling on the Whitehead link (cf. [1]), we shall prove:

1.9 Proposition All but finitely many punctured torus bundles with tunnel number one are infinitesimally projectively rigid.

All but finitely many twist knots complements are infinitesimally projectively rigid.

The real hyperbolic space $H^3$ naturally embeds in the complex hyperbolic space $H^3_C$. We may study the corresponding deformation theory coming from viewing $PSO(3,1) = \Isom^+(H^3)$ in $PSU(3,1) = \Isom_0(H^3_C)$, i.e. the identity component of complex hyperbolic isometries.

1.10 Definition We say that $M$ is infinitesimally $H^3_C$-rigid if the sequence

$$0 \rightarrow H^1(M; su(3,1)_{Ad \rho}) \rightarrow H^1(\partial M; su(3,1)_{Ad \rho})$$

is exact

In particular, if $\partial M = \emptyset$, then we require $H^1(M; su(3,1)_{Ad \rho}) = 0$. The study of deformations in $PGL(4)$ and $PSU(3,1)$ are related, as we shall see in Subsection 3.3. In particular we have the following theorem of Cooper, Long and Thistlethwaite.

1.11 Theorem [10] Let $M^n$ be a real hyperbolic manifold of finite volume, $n \geq 3$. Then $M^n$ is infinitesimally projectively rigid if and only if $M^n$ is infinitesimally $H^3_C$-rigid

4
This equivalence is described by means of Lie algebras, and it is used along the paper, because some things are easier to understand in the complex hyperbolic setting instead of the projective one.

The article is organized as follows. In Section 2 we recall Thurston’s construction of deformations of hyperbolic structures and the generalized Dehn filling coefficients. In Section 3 we introduce the main tools in order to study infinitesimal deformations. The next two sections are devoted to cohomology computations, namely in Section 4 we compute invariant subspaces of the Lie algebras and in Section 5 we analyze the image in cohomology of the restriction to the torus boundary. The proof of Theorems 1.4 and 1.5 is given in Section 6 by means of an analytic function on the deformation space: when this function does not vanish, then the corresponding Dehn filling is infinitesimally rigid. To prove Propositions 1.7 and 1.9 we require the notion of flexing slope, treated in Section 7, as well as explicit computations on the figure eight knot and the Whitehead link exteriors, made in Section 8.

2 Dehn filling and Thurston’s slice

In this section we recall the deformation space introduced by Thurston in his proof of hyperbolic Dehn filling theorem [29].

Along the paper, $M$ denotes a compact manifold with boundary a union of $k > 0$ tori and hyperbolic interior:

$$\partial M = \partial_1 M \sqcup \cdots \sqcup \partial_k M,$$

where each $\partial_i M \cong T^2$.

The deformation space of hyperbolic structures is described by the Thurston slice. Given $\lambda_i, \mu_i \in \pi_1(\partial M)$ a pair of simple closed curves that generate the fundamental group on each component $\partial M_i$, Thurston introduced a parameter

$$u = (u_1, \ldots, u_k) \in U \subset \mathbb{C}^k,$$

defined on $U$ a neighborhood of 0. The neighborhood $U$ parametrizes the deformations of the complete holonomy of the interior of $M$. Two structures parametrized by $u$ and $u' \in U$ are equivalent (the developing maps differ by composing with an isometry of $\mathbb{H}^3$) if and only if

$$(u_1, \ldots, u_k) = (\pm u'_1, \ldots, \pm u'_k).$$

(1)

This is a consequence of the fact that (1) is a criterion for having the same character, and the fact that deformations are parametrized by conjugacy classes of holonomy [7].
2.1 Theorem (Thurston’s slice) There exists an open neighborhood \( 0 \in U \subseteq \mathbb{C}^k \), an analytic family of representations \( \{ \rho_u \}_{u \in U} \) of \( \pi_1(M) \) in \( \text{PSL}_2(\mathbb{C}) \) and analytic functions \( v_i = v_i(u) \), \( i = 1, \ldots, k \) so that:

(i) The parameters \( u_i \) and \( v_i \) are the complex length of \( \rho_u(\mu_i) \) and \( \rho_u(\lambda_i) \) respectively.

(ii) The function \( \tau_i(u) = v_i(u)/u_i \) is analytic. Moreover \( v_i = \tau_i(0)u_i + (|u|^3) \), where \( \tau_i(0) \in \mathbb{C} \) is the cusp shape and has nonzero imaginary part.

(iii) The structure with holonomy \( \rho_u \) is complete on the \( i \)-th cusp if and only if \( u_i = 0 \).

(iv) When \( u_i \neq 0 \), the equation

\[
p_i u_i + q_i v_i = 2\pi i
\]

has a unique solution for \( (p_i, q_i) \in \mathbb{R}^2 \). The representation \( \rho_u \) is the holonomy of a incomplete hyperbolic structure with generalized Dehn filling coefficients \( (p_i, q_i) \) on the \( i \)-th cusp.

See [4, App. B] for a proof, for instance.

In his proof of hyperbolic Dehn filling, Thurston shows that there is a diffeomorphism between \( U \) and a neighborhood of \( \infty \) in \( (\mathbb{R}^2 \cup \{\infty\})^k \) that maps componentwise 0 to \( \infty \) and \( u_i \neq 0 \) to \( (p_i, q_i) \in \mathbb{R}^2 \) satisfying \( p_i u_i + q_i v_i = 2\pi i \).

The geometric interpretation of generalized Dehn filling coefficients is the following one:

(i) When \( p_i, q_i \in \mathbb{Z} \) are coprime, then the completion for \( \rho_u \) is precisely the Dehn filling with slope \( p_i \mu_i + q_i \lambda_i \).

(ii) When \( p_i/q_i = p'_i/q'_i \in \mathbb{Q} \cup \{\infty\} \) with \( p'_i, q'_i \in \mathbb{Z} \) coprime, then the completion for \( \rho_u \) is a cone manifold, obtained by Dehn filling with slope \( p'_i \mu_i + q'_i \lambda_i \) where the core of the torus is a singular geodesic with cone angle \( 2\pi p'_i/p_i \).

(iii) When \( p_i/q_i \in \mathbb{R} \setminus \mathbb{Q} \), then the metric completion is the one point compactification.

A particular case that we will use later is when \( u_i = \alpha_i i \) for some \( \alpha_i \in \mathbb{R} \), \( \alpha_i > 0 \). Then \( p_i = 2\pi/\alpha_i \) and \( q_i = 0 \), and \( \rho_{(\alpha_1, \ldots, \alpha_k)} \) is the holonomy of a hyperbolic cone manifold with cone angles \( (\alpha_1, \ldots, \alpha_k) \).

The real analytic structure will be crucial in our arguments. When viewed in \( \text{PSL}_2(\mathbb{C}) \), \( \rho_u \) is complex analytic, but we will work with the real analytic structure, which is the same as for \( \text{PSO}(3,1) \). In particular the following lemma will be useful.
2.2 Lemma For each \( i = 1, \ldots, k \), if \( \tau_i(u) = v_i(u)/u_i \), then the map
\[
U \subset C^k \rightarrow \mathbb{R}^2 \quad u \mapsto \frac{1}{|p_i + q_i\tau_i|^2}(p_i, q_i)
\]
is real analytic.

Proof. Using Equation (2), we obtain:
\[
p_i = -2\pi \frac{Re(u_i\tau_i)}{|u_i|^2 Im(\tau_i)}, \quad q_i = 2\pi \frac{Re(u_i)}{|u_i|^2 Im(\tau_i)}, \quad p_i + q_i\tau_i = \frac{2\pi i}{u_i}.
\]
The lemma is a straightforward consequence from these equalities and the fact that the imaginary part of \( \tau_i(0) \) does not vanish.

3 Infinitesimal deformations

The matrix of the Lorentzian inner product is denoted by
\[
J = \begin{pmatrix}
1 & 1 \\
1 & -1
\end{pmatrix}.
\]
So that
\[
O(3,1) = \{ A \in GL(4) \mid A^tJA = J \},
\]
and the connected component of the identity of its projectivization \( PSO(3,1) \) is the group of orientation preserving isometries of \( H^3 \). Its Lie algebra is
\[
\mathfrak{so}(3,1) = \{ a \in \mathfrak{sl}(4) \mid a^tJ = -Ja \}.
\]

Following Johnson and Millson [17], along the paper we shall use the decomposition of \( \mathfrak{sl}(4) \) as direct sum of \( PSO(3,1) \)-modules via the adjoint action:
\[
\mathfrak{sl}(4) = \mathfrak{so}(3,1) \oplus \mathfrak{v}, \quad (3)
\]
where
\[
\mathfrak{v} = \{ a \in \mathfrak{sl}(4) \mid a^tJ = Ja \}.
\]
Notice that \( \mathfrak{v} \) is not a Lie algebra, but just a \( PSO(3,1) \)-module.

Hence given a representation \( \rho: \pi_1(M) \rightarrow PSO(3,1) \) we obtain a canonical splitting in homology:
\[
H^*(M; \mathfrak{sl}(4)_{Ad\rho}) = H^*(M; \mathfrak{so}(3,1)_{Ad\rho}) \oplus H^*(M; \mathfrak{v}_{Ad\rho}).
\]
In the remaining of the section, we shall recall the known results about the cohomology group \( H^1(M; \mathfrak{so}(3,1)_{Ad\rho}) \) (Subsection 3.1) and provide some properties of \( H^*(M; \mathfrak{v}_{Ad\rho}) \).
3.1 Infinitesimal deformations in real hyperbolic space

Infinitesimal deformations in Isom\(^\dagger\)(H) = PSO(3, 1) are well understood, and described by \(H^1(M; \mathfrak{so}(3, 1)_{\text{Ad}_\rho})\). We summarize here the main results:

3.1 Proposition Let \(M\) be a finite volume hyperbolic 3-manifold with \(k\) cusps and let \(U\) be as in Theorem 2.1. For all \(u \in U\):

(i) The inclusion \(\partial M \subset M\) induces a monomorphism
\[
0 \to H^1(M; \mathfrak{so}(3, 1)_{\text{Ad}_\rho_u}) \to H^1(\partial M; \mathfrak{so}(3, 1)_{\text{Ad}_\rho_u}).
\]

(ii) If we choose one essential simple closed curve \(\mu_i \subset \partial_i M\) for each boundary component, then the inclusion of the union \(\mu = \mu_1 \cup \cdots \cup \mu_k \subset M\) induces a monomorphism
\[
0 \to H^1(M; \mathfrak{so}(3, 1)_{\text{Ad}_\rho_u}) \to H^1(\mu; \mathfrak{so}(3, 1)_{\text{Ad}_\rho_u}).
\]

(iii) \(\dim H^1(M; \mathfrak{so}(3, 1)_{\text{Ad}_\rho_u}) = 2k\).

(iv) \(\dim H^1(M, \mu; \mathfrak{so}(3, 1)_{\text{Ad}_\rho_u}) = 2k\).

This proposition can be seen as the algebraic part of Thurston’s hyperbolic Dehn filling theorem. When \(\partial M = \emptyset\) it is due to Weil [31], and when \(\partial M \neq \emptyset\), it is Garland rigidity [12]. See [19] or [12] for a proof.

3.2 Killing form, cup product and Kronecker pairing in \(v\)

The Killing form on any Lie algebra \(\mathfrak{g}\) is defined as:
\[
B(X, Y) = \text{trace}(\text{ad}_X \circ \text{ad}_Y) \quad \forall X, Y \in \mathfrak{g},
\]
where \(\text{ad}_X \in \text{End}(\mathfrak{g})\) denotes the endomorphism given by \(\text{ad}_X(Y) = [X, Y]\).

If \(\mathfrak{g} = \mathfrak{sl}(4)\), then \(B(X, Y) = 8 \text{tr}(X \cdot Y)\).

Both the form \(B\) on \(\mathfrak{sl}(4)\) and its restriction to \(\mathfrak{so}(3, 1)\) are nondegenerate. Moreover \(v\) is the orthogonal complement to \(\mathfrak{so}(3, 1)\):
\[
\mathfrak{sl}(4) = \mathfrak{so}(3, 1) \perp v.
\]

Therefore \(B\) restricted to \(v\) is nondegenerate.

A cup product on cohomology is defined by using \(B\):
\[
H^p(M; v) \otimes H^q(M, \partial M; v) \xrightarrow{\cup} H^{p+q}(M, \partial M; v \otimes v) \xrightarrow{B_*} H^{p+q}(M, \partial M; \mathbb{R})
\]
where the first arrow is the usual cup product, and \(B_*\) denotes the map induced by \(B : v \otimes v \to \mathbb{R}\). Since we do not use any other cup product, this one will be simply denoted by \(\cup\). This cup product induces Poincaré
duality since $B$ is non degenerated, cf. [17]. As $B$ is symmetric, this cup product is symmetric or antisymmetric depending on whether the product of dimensions $pq$ is even or odd, as the usual cup product.

The Killing form is also used to define a Kronecker pairing between homology and cohomology. Consider $C_*(\tilde{M})$ the group of chains of the universal covering, with the action of $\pi_1(M)$. The chain group is the tensor product $v \otimes_{\pi_1 M} C_*(\tilde{M})$, so that a cycle is an element $\sum v_i \otimes c_i$, $c_i \in C_*(\tilde{M})$ and $v_i \in v$. Moreover the cochain group is the set of morphisms $\text{Hom}_{\pi_1 M}(C_*(\tilde{M}); v)$, and a cocycle is a morphism of $\pi_1 M$-modules, $\theta : C_*(\tilde{M}) \to v$. Then the Kronecker pairing is given by:

$$H^p(M; v) \times H_0(M; v) \rightarrow \mathbb{R} \ \ \ [\theta] \ \ \ [\sum_i v_i \otimes c_i] \rightarrow \sum_i B(\theta(c_i), v_i). \quad (5)$$

This pairing gives duality between homology and cohomology.

### 3.3 Complex hyperbolic space

Consider $\mathbb{C}^{3,1}$ i.e. $\mathbb{C}^4$ with the hermitian product

$$\langle w, z \rangle = w_1 \bar{z}_1 + w_2 \bar{z}_2 + w_3 \bar{z}_3 - w_4 \bar{z}_4 = w^t J \bar{z} = \bar{z}^t w$$

where $z^* = \bar{z}^t J$. Its projectivization $\mathbb{P}^{3,1} := \mathbb{P}(\mathbb{C}^{3,1})$ gives rise to complex hyperbolic space $H^3_\mathbb{C}$. More precisely, $H^3_\mathbb{C} = \{ [v] \in \mathbb{P}^{3,1} \mid \langle v, v \rangle < 0 \}$ cf. [13][11]. Here and in the sequel $[v]$ denotes the line generated by the non zero vector $v \in \mathbb{C}^{3,1}$.

Let

$$SU(3, 1) = \{ A \in SL(4, \mathbb{C}) \mid \bar{A}^t J A = J \}.$$ 

The group of holomorphic isometries of complex hyperbolic space is its projectivization $PSU(3, 1) = PU(3, 1)$, with Lie algebra:

$$\mathfrak{su}(3, 1) = \{ a \in \mathfrak{sl}(4, \mathbb{C}) \mid \bar{a}^t J = -Ja \}.$$ 

The key point is that, as $SO(3, 1)$-module, this Lie algebra has a decomposition:

$$\mathfrak{su}(3, 1) = \mathfrak{so}(3, 1) \perp i v. \quad (6)$$

Thus:

#### 3.2 Remark

The subspace $v = \{ a \in \mathfrak{sl}(4) \mid a^t J = Ja \}$ can be seen as the imaginary part of infinitesimal deformations in complex hyperbolic space.

**Proof of Theorem 1.11.** Equation (6) holds true in any dimension, and, since it is an isomorphism of $PSO(n, 1)$-modules, it gives an isomorphism in cohomology:

$$H^1(M; \mathfrak{sl}(n + 1)) = H^1(M; \mathfrak{so}(n, 1)) \oplus H^1(M; v) \cong H^1(M; \mathfrak{su}(n, 1)) \oplus H^1(M; v).$$
Using this isomorphism, the proof follows.

We will use Remark 3.2 and Equation (6) to understand the computations for the cohomology with coefficients in \( v \) in a Riemannian setting.

In order to understand the Killing form on \( \mathfrak{su}(3,1) \) we follow the exposition of Goldman [13, 4.1.3]. Let

\[
v_+ = \begin{pmatrix} 0 \\ 0 \\ 1 \\ 1 \end{pmatrix} \quad \text{and} \quad v_- = \begin{pmatrix} 0 \\ 0 \\ -1 \\ 1 \end{pmatrix}
\]

be two null vectors in \( \mathbb{C}^{3,1} \) representing two distinct boundary points of \( H^3_{\mathbb{C}} \). Then the element

\[
\eta := -\frac{1}{2}(v_+ v_-^* - v_- v_+^*) = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \end{pmatrix}
\]

is the infinitesimal generator of a 1-parameter subgroup of isometries fixing the points \([v_+] \in \partial H^3_{\mathbb{C}}\) and translating along the geodesic between \([v_+]\) and \([v_-]\).

Decompose the Lie algebra \( \mathfrak{su}(3,1) \) into eigenspaces

\[
\mathfrak{g}_k = \text{Ker}(\text{ad}_\eta - k \mathbf{I})
\]

of \( \text{ad}_\eta \). The eigenspace \( \mathfrak{g}_k \) is nonzero only for \( k \in \{0, \pm 1, \pm 2\} \). More explicitly we have:

\[
\mathfrak{g}_0 = \left\{ \begin{pmatrix} a \\ 0 \\ -\frac{\text{tr}(a)}{2} \\ t \end{pmatrix} \middle| \begin{array}{c} a \\ 0 \\ -\frac{\text{tr}(a)}{2} \\ t \end{array} \in \mathfrak{u}(2), \ t \in \mathbb{R} \right\},
\]

\[
\mathfrak{g}_{\pm 1} = \{ v v_+^* - v_+ v^* \mid v \in V(v_+) \} \quad \text{and} \quad \mathfrak{g}_{\pm 2} = \{ iv v_+^* \mid s \in \mathbb{R} \}
\]

where \( V(v_+) \) denotes the vector space generated by \( v_+ \) and \( v_- \). Note that \( V(v_-) \) is the positive two-dimensional complex subspace of \( \mathbb{C}^{3,1} \) given by \( z_3 = z_4 = 0 \).

As usual we have \( [\mathfrak{g}_k, \mathfrak{g}_l] \subset \mathfrak{g}_{k+l} \) with the convention that \( \mathfrak{g}_{k+l} = 0 \) if \( |k + l| > 2 \). This tells us immediately that \( \mathfrak{g}_k \) is orthogonal with respect to the Killing form to \( \mathfrak{g}_l \) for all \( k \neq -l \).

Now let \( G_\pm \subset \text{PSU}(3,1) \) denote the stabilizer of the point \([v_+] \in \partial H^3_{\mathbb{C}}\).

The Lie algebra \( \mathfrak{g}_\pm \) of \( G_\pm \) is given by

\[
\mathfrak{g}_\pm = \mathfrak{g}_0 \oplus \mathfrak{g}_{\pm 1} \oplus \mathfrak{g}_{\pm 2}.
\]

Note also that \( \mathfrak{h}_\pm = \mathfrak{g}_{\pm 1} \oplus \mathfrak{g}_{\pm 2} \) is the Lie algebra of parabolic transformations fixing the point \([v_+]\).

As a consequence of this discussion we obtain the following lemma.
3.3 Lemma The Killing form of \( \mathfrak{su}(3,1) \) restricted to \( \mathfrak{g}_\pm \) is degenerated. More precisely, the radical \( \text{rad}(\mathfrak{g}_\pm) = \mathfrak{g}_\pm \cap \mathfrak{g}_\pm^\perp = \mathfrak{h}_\pm \) consist exactly the infinitesimal parabolic transformations.

Proof. Let us consider the sign +, the other case is analogous. We have 
\[ \mathfrak{g}^\perp_0 = \mathfrak{h}_+ \oplus \mathfrak{h}_- \quad \mathfrak{g}^\perp_1 = \mathfrak{g}_0 \oplus \mathfrak{h}_+ \oplus \mathfrak{g}_{-2} \quad \mathfrak{g}^\perp_2 = \mathfrak{g}_0 \oplus \mathfrak{h}_+ \oplus \mathfrak{g}_{-1} \]

This follows since \( \mathfrak{g}_k \) is orthogonal with respect to the Killing form to \( \mathfrak{g}_l \) for all \( k \neq -l \). Hence \( \mathfrak{g}_+ \cap \mathfrak{g}^\perp_0 = \mathfrak{g}_+ \cap \mathfrak{g}^\perp_0 \cap \mathfrak{g}^\perp_1 \cap \mathfrak{g}^\perp_2 = \mathfrak{h}_+ = \mathfrak{g}_1 \oplus \mathfrak{g}_2 \). \( \Box \)

4 Invariant subspaces in complex hyperbolic geometry

In this section we shall compute subspaces of the module \( \mathfrak{v} \) that are invariant by certain elements of \( P\text{SO}(3,1) \). This will be used later when computing cohomology. For a set of hyperbolic isometries \( \Gamma \subset P\text{SO}(3,1) \), we shall compute the invariant subspace in \( \mathfrak{v} \):
\[ \mathfrak{v}^\Gamma = \{ v \in \mathfrak{v} \mid \text{Ad}_\gamma(v) = v, \forall \gamma \in \Gamma \} \]

For our computations, we will view elements in \( \mathfrak{v} \) as lying in \( i\mathfrak{v} \), namely as infinitesimal isometries of \( H^3_{\mathbb{C}} \). We also use the following lemma (see [5, III.9.3] for a proof).

4.1 Lemma For \( \gamma \in \text{PSU}(3,1) \), \( \mathfrak{su}(3,1)\gamma = \text{Ker}(\text{Ad}_\gamma - 1) \) is the Lie algebra of the centralizer of \( \gamma \) (i.e. the Lie subgroup of elements in \( \text{PSU}(3,1) \) that commute with \( \gamma \)).

Alternatively, the computation of invariant subspaces could also be made with the analogue of Lemma 4.1 for \( GL(4) \) or just by explicit computation of the adjoint action on \( \mathfrak{v} \).

The centralizer of an element is obtained by means of the stabilizer of an invariant object in \( H^3_{\mathbb{C}} \cup \partial H^3_{\mathbb{C}} \). This explains the organization of this section, one subsection for each object.

4.1 Geodesics.

Consider the Riemannian geodesic \( \gamma \) in \( H^3_{\mathbb{C}} \) between \([v_+]\) and \([v_-]\). Let \( \mathfrak{g}_0 \subset \mathfrak{su}(3,1) \) denote the Lie algebra of the subgroup \( G_0 \subset \text{PSU}(3,1) \) which fixes the endpoints of the geodesic \( \gamma \) (see [13, 4.1.3]). Notice that \( G_0 \cong \mathbb{R} \times U(2) \), where \( \mathbb{R} \) acts by translations and \( U(2) \) is the pointwise stabilizer, isomorphic to the stabilizer of a point in \( H^2_{\mathbb{C}} \), hence \( \mathfrak{g}_0 \cong \mathbb{R} \oplus \mathfrak{u}(2) \).

4.2 Lemma Let \( A \in \text{PSO}(3,1) \) be a hyperbolic element of complex length \( l + i \alpha, \ l \neq 0 \).
(i) If $\alpha \notin \pi \mathbb{Z}$, then $\dim v^A = 1$.

(ii) If $\alpha \in \pi \mathbb{Z}$, then $\dim v^A = 3$.

**Proof.** We let $\gamma$ denote the axis of $A$. After conjugation we might assume that $\gamma$ is the geodesic between $[v_+]$ and $[v_-]$ and hence

$$A = \begin{pmatrix}
\cos \alpha & -\sin \alpha & 0 & 0 \\
\sin \alpha & \cos \alpha & 0 & 0 \\
0 & 0 & \cosh l & \sinh l \\
0 & 0 & \sinh l & \cosh l
\end{pmatrix}.$$

If $\alpha = \pi$, then $A$ commutes with the whole stabilizer $G_0$. Moreover, the subgroup of $PSO(3,1)$ preserving $\gamma$ is isomorphic to $P(O(2) \times O(1,1))$. Thus

$$\dim v^A = \dim(g_0) - \dim(\mathfrak{so}(2) \oplus \mathfrak{so}(1,1)) = 5 - 2 = 3.$$

If $\alpha \neq \pi$, then the Lie algebra of the centralizer of $A$ in $su(3,1)$ is isomorphic to $\mathbb{R} \oplus (\mathfrak{so}(2) \times u(1)) \subset \mathbb{R} \oplus u(2)$, hence three-dimensional and therefore

$$\dim v^A = 3 - 2 = 1.$$

\[\square\]

### 4.2 Complex hyperbolic lines

Complex hyperbolic space is the projectivization of the subset of the time-like vectors of $\mathbb{C}^{3,1}$. A *complex hyperbolic line* is defined as the intersection of $H^3_{\mathbb{C}}$ with a complex projective line. The group $SU(3,1)$ acts transitively on the set of complex planes that contain time-like vectors. Hence all complex hyperbolic lines are isomorphic to $H^3_{\mathbb{C}}$, and a standard model for a complex hyperbolic line is the image of the plane given by $x_1 = x_2 = 0$. The intersection of a complex hyperbolic line with $\partial H^3_{\mathbb{C}}$ is a smooth circle called a *chain*. Two distinct boundary points of $H^3_{\mathbb{C}}$ are contained in a unique chain and the Riemannian geodesic between the two boundary points is contained in the corresponding complex hyperbolic line.

The identity component of the stabilizer of a chain is given by $P(U(2) \times U(1,1)) \subset PSU(3,1)$.

**4.3 Lemma** Let $A \in PSO(3,1)$ be an elliptic element of rotation angle $\alpha \in (0, 2\pi)$.

(i) If $\alpha = \pi$, then $\dim v^A = 5$.

(ii) If $\alpha \neq \pi$, then $\dim v^A = 3$.
Proof. The fixed point set of $A$ is a complex line, whose stabilizer is $P(U(2) \times U(1,1))$.

If $\alpha = \pi$ then $A$ commutes with all elements in this stabilizer. As the stabilizer of a geodesic in $PSO(3,1)$ is two dimensional $(SO(2) \times R)$ we obtain:

$$\dim \mathfrak{v}^A = \dim((u(1,1) \oplus u(2)) - 1 - \dim(so(2) \oplus R)$$

$$= \dim u(1,1) + \dim u(2) - 3 = 4 + 4 - 3 = 5.$$

When $\alpha \neq \pi$, then the centralizer of $A$ is the projectivization of

$$\left\{ \begin{pmatrix} \zeta C & 0 \\ 0 & B \end{pmatrix} \bigg| C \in SO(2), \; \zeta \in U(1), \; B \in U(1,1) \right\}$$

and therefore

$$\dim \mathfrak{v}^A = \dim(u(1,1) \oplus so(2)) - 2$$

$$= 4 + 1 - 2 = 3.$$

\[\square\]

4.3 Parabolic elements and Heisenberg geometry

In the sequel we will use the notation of Section 3.3 i.e. we will fix two light-like vectors $v_\pm \in \mathbb{C}^{3,1}$ representing two distinct boundary points $[v_\pm] \in \partial \mathbb{H}_3^C$. Moreover we will use the root-space decomposition of $\mathfrak{su}(3,1)$. The Heisenberg group $\mathcal{H}_- \mathbb{C}$ is the group of parabolic transformations fixing the point $[v_-]$, i.e. $\exp: g_- \oplus g_- \rightarrow \mathcal{H}_- \mathbb{C}$ is given by

$$\exp(v_-v^* + i v_-v^* + \mathbb{R}^1 \times v_-v^*)$$

$$= I_4 + v_-v^* - vv^* - (\|v\|^2/2 - it)v_-v^*$$

$$= \begin{pmatrix}
1 & 0 & z_1 & z_1 \\
0 & 1 & z_2 & z_2 \\
-\bar{z}_1 & -\bar{z}_2 & 1 - \|v\|^2/2 + it & -\|v\|^2/2 + it \\
z_1 & \bar{z}_2 & \|v\|^2/2 - it & 1 + \|v\|^2/2 - it
\end{pmatrix}$$

$$=: H(z_1, z_2, t) \quad (7)$$

where $v = (z_1, z_2, 0, 0)^t \in v^+ \cap v^-_H$ is a space-like vector and hence $\langle v, v \rangle = \|v\|^2 = |z_1|^2 + |z_2|^2 \geq 0$.

Following the exposition in Goldman’s book [13 4.2], the boundary a $\infty$ of $\mathbb{H}_3^C$ minus the point $[v_-]$ can be identified with a $Heisenberg$ $space$, i.e. a space equipped with a simply transitive left action of the Heisenberg group $\mathcal{H}_- \mathbb{C}$. Hence by looking at the orbit of $[v_+]$ we have a bijection $\mathcal{H}_- \rightarrow$
\( \partial \mathbb{H}_C^3 \setminus \{v_-\} \) given by

\[
H(z_1, z_2, t) \mapsto H(z_1, z_2, t)[v_+] = \begin{bmatrix} \frac{2z_1}{1 - \|z\|^2 + 2it} \\ \frac{2z_2}{1 + \|z\|^2 - 2it} \end{bmatrix}
\]

where \( \|z\|^2 = |z_1|^2 + |z_2|^2 \).

In the sequel we shall represent points of \( \mathcal{H}_- \) by triples of points \((z_1, z_2, t)\) where \(z_1, z_2 \in \mathbb{C}, \ t \in \mathbb{R}\) with multiplication

\[
(\omega_1, \omega_2, s) \cdot (z_1, z_2, t) = (\omega_1 + z_1, \omega_2 + z_2, s + t + \text{Im}(\omega_1 \bar{z}_1 + \omega_2 \bar{z}_2)),
\]

\( \forall (\omega_1, \omega_2, s), (z_1, z_2, t) \in \mathcal{H}_- \). \( (8) \)

Therefore, \( \mathcal{H}_- \) is a nilpotent 5-dimensional real Lie group, which is a non-trivial central extension

\[ 0 \to \mathbb{R} \to \mathcal{H}_- \to \mathbb{C}^2 \to 0. \]

The center are the elements of the form \((0, 0, t), \ t \in \mathbb{R}\).

In the sequel we will make use of the Siegel domain model \( \mathcal{S}^3 \) of \( \mathbb{H}_C^3 \). Here

\[
\mathcal{S}^3 = \left\{ w = \begin{pmatrix} w_1 \\ w_2 \\ w_3 \end{pmatrix} \in \mathbb{C}^3 \mid |w_1|^2 + |w_2|^2 < 2 \text{Re}(w_3) \right\}
\]

is obtained in the following way: we choose the point \([v_-] \in \partial \mathbb{H}_C^3\) and we denote by \( H \subset \mathbb{P}^3 \) the projective hyperplane tangent to \( \partial \mathbb{H}_C^3 \) at \([v_-]\). More precisely, \( H \) is the projectivization of \( v_+^\perp \subset \mathbb{C}^3 \) given by the equation \( z_3 + z_4 = 0 \). The corresponding affine embedding \( \mathbb{C}^3 \to \mathbb{CP}^3 \setminus H \) is given by

\[
\begin{pmatrix} w_1 \\ w_2 \\ w_3 \end{pmatrix} \mapsto \begin{pmatrix} w_1 \\ w_2 \\ 1/2 - w_3 \\ 1/2 + w_3 \end{pmatrix}.
\]

It is easy to see that \( \mathbb{H}_C^3 \) correspond to the Siegel domain \( \mathcal{S}^3 \subset \mathbb{C}^3 \). In this model the whole stabilizer \( G_- \) of the point \([v_-]\) at infinity is the semidirect product:

\[ G_- = \mathcal{H}_- \rtimes (U(2) \times \mathbb{R}). \]

Here \( U(2) \) acts linearly on the factor \( \mathbb{C}^2 \), and trivially on the factor \( \mathbb{R} \). Moreover \( \mathbb{R} \) acts as follows:

\[
(I_2, \lambda)(z_1, z_2, t)(I_2, -\lambda) = (e^{-\lambda z_1}, e^{-\lambda z_2}, e^{-2\lambda t}), \ \forall \lambda \in \mathbb{R}, \ \forall (z_1, z_2, t) \in \mathcal{H}.
\]

In this construction, the subgroup of real parabolic transformations corresponds to \( \mathbb{R}^2 \times \{0\} \subset \mathcal{H}_- \).
4.4 Lemma  
(i) If $A$ is a nontrivial parabolic element of $PSO(3,1)$, then $\dim v^A = 3$.

(ii) If $\Gamma < PSO(3,1)$ is a rank 2 parabolic subgroup, then $\dim v^\Gamma = 1$.

Proof. Using the representation in the Heisenberg group $H_-$, we may assume that up to conjugation $A$ is $(1,0,0) \in H_-$. Note that the centralizer of $A$ is contained in $G_-$. This follows from the fact that $A$ has a unique fixed point on $H^R_C$ and every element which commutes with $A$ has to fix this point.

Now a direct calculation gives that the centralizer of $A$ in $G_-$ is 5-dimensional and given by
\[
\{(s, z, t) \begin{pmatrix} 1 & 0 \\ 0 & a \end{pmatrix} \in G_- \mid s, t \in \mathbb{R}, z \in \mathbb{C} \text{ and } a \in U(1)\}.
\]

Thus $\dim(\mathfrak{su}(3,1)^A) = 5$, and since $\dim(\mathfrak{so}(3,1)^A) = 2$ (the tangent space to the real parabolic group itself), the first assertion follows.

For the last assertion, we view $\Gamma$ as a rank 2 subgroup of the Heisenberg group $\Gamma < \mathbb{R}^2 \times \{0\} < H_-$. Its centralizer is contained in $G_-$ and is precisely the subgroup of elements with real coordinates:
\[
\mathbb{R}^3 \cong \{(s_1, s_2, t) \in H_- \mid s_1, s_2, t \in \mathbb{R}\} < H_-.
\]

As the subgroup of real parabolic transformations $\mathbb{R}^2 \times \{0\}$ is the centralizer of $\Gamma$ in $PSO(3,1)$, it follows that $v^\Gamma = \{(0,0)\} \times \mathbb{R}$ is one dimensional. \qed

5 Cohomology of the torus

In this section, we analyze the cohomology of the boundary $\partial M$ and the image of the map induced by inclusion $\partial M \subset M$, which is a Lagrangian subspace.

5.1 A Lagrangian subspace

As in Section 2 let $\rho_u$ denote a representation contained in Thurston’s slice, where $u = (u_1, \ldots, u_k) \in U \subset \mathbb{C}^k$ is a point in the deformation space. The subspace invariant by the image of the peripheral subgroup of the $i$-th component is denoted by $v^{\rho_u(\pi_1(\partial_i M))}$, and its orthogonal complement by
\[
(v^{\rho_u(\pi_1(\partial_i M))})^\perp = \{v \in v \mid B(v, w) = 0, \forall w \in v^{\rho_u(\pi_1(\partial_i M))}\}.
\]
5.1 Lemma

(i) For \( u_i \neq 0 \), the radical of \( \mathfrak{v}^{\rho_u}(\pi_1(\partial,M)) \) is trivial, i.e.
\[
(\mathfrak{v}^{\rho_u}(\pi_1(\partial,M)))^\perp \cap \mathfrak{v}^{\rho_u}(\pi_1(\partial,M)) = 0.
\]

(ii) For every \( u \in U \), the invariant subspace \( \mathfrak{v}^{\rho_u}(\pi_1(\partial,M)) \) has dimension one.

Proof. When \( u_i \neq 0 \), \( \rho_u(\pi_1(\partial,M)) \) consists of loxodromic and/or elliptic elements that preserve a geodesic, and we want to apply Lemma 4.2 (i). For this, we need an element \( \gamma \in \pi_1(\partial,M) \) such that \( \rho_u(\gamma) \) satisfies the hypothesis of Lemma 4.2 (i). If the real part of \( u_i \) does not vanish and the imaginary part of \( u_i \) is not contained in \( \mathbb{Z}\pi \) then we choose \( \mu_i \). If the real part of \( u_i \) vanishes, by Theorem 2.1 the real part of \( v_i \) does not, and the condition on the complex length applies to either \( \gamma = \lambda_i \) or \( \gamma = \lambda_i \mu_i \), that have respective complex lengths \( v_i \) and \( u_i + v_i \). The same argument applies when the imaginary part of \( u_i \) is zero.

By Lemma 4.2 (i) and its proof, \( \mathfrak{v}^{\rho_u}(\pi_1(\partial,M)) \) is the one dimensional subspace generated by (a conjugate of)
\[
\begin{pmatrix}
1 & 1 \\
-1 & -1
\end{pmatrix},
\]
and both assertions of the lemma are clear when \( u_i \neq 0 \).

When \( u_i = 0 \), assertion (ii) is Lemma 4.4 (ii). \(\square\)

Note that the cup product on \( H^1(\partial M; \mathfrak{v}) \) is the orthogonal sum of the cup products on the groups \( H^1(\partial_i M; \mathfrak{v}) \). More precisely, if we denote by \( \text{res}_i : H^1(\partial M; \mathfrak{v}) \to H^1(\partial_i M; \mathfrak{v}) \) the restriction induced by the inclusion \( \partial_i M \hookrightarrow \partial M \) then for \( z_1, z_2 \in H^1(\partial M; \mathfrak{v}) \) we have
\[
z_1 \cup z_2 = \sum_{i=1}^k \text{res}_i(z_1) \cup \text{res}_i(z_2). \tag{9}
\]

5.2 Lemma Let \( u = (u_1, \ldots, u_k) \in U \).

(i) When \( u_i \neq 0 \), there is a natural isomorphism
\[
H^*(\partial_i M; \mathfrak{v}_{\text{Ad}}) \cong H^*(\partial_i M; \mathfrak{r}) \otimes \mathfrak{v}^{\rho_u}(\pi_1(\partial,M)).
\]

(ii) For \( u \in U \), \( \dim H^1(\partial M; \mathfrak{v}_{\text{Ad}}) = 2k \), and the image of the map
\[
H^1(M; \mathfrak{v}_{\text{Ad}}) \to H^1(\partial M; \mathfrak{v}_{\text{Ad}})
\]
is a Lagrangian subspace of \( H^1(\partial M; \mathfrak{v}_{\text{Ad}}) \) for the cup product (in particular it has dimension \( k \)).
Proof. To prove assertion (i), we use the decomposition of Lemma 5.1:

\[ \nu = (\nu^{\rho u(\pi_1(\partial M))})^\perp \oplus \nu^{\rho u(\pi_1(\partial M))}, \]

which is a direct sum of \( \pi_1(\partial M) \)-modules, and therefore it induces a direct sum in cohomology. Since \( (\nu^{\rho u(\pi_1(\partial M))})^\perp \) has no invariant subspaces,

\[ H^0(\partial_i M, (\nu^{\rho u(\pi_1(\partial M))})^\perp) = 0. \]

In addition, the Killing form restricted to \( (\nu^{\rho u(\pi_1(\partial M))})^\perp \) is non-degenerate, thus by duality and by vanishing of the Euler characteristic

\[ H^*(\partial_i M, (\nu^{\rho u(\pi_1(\partial M))})^\perp) = 0. \]

Hence

\[ H^*(\partial_i M; \nu) = H^*(\partial_i M; \nu^{\rho u(\pi_1(\partial M))}) \cong H^*(\partial_i M; R) \otimes \nu^{\rho u(\pi_1(\partial M))}. \]

The proof of assertion (ii) is a standard application of duality, that we reproduce for completeness (cf. [15]). We are interested in the following part of the exact cohomology sequence of the pair \( (M, \partial M) \):

\[ H^1(M; \nu) \xrightarrow{j^*} H^1(\partial M; \nu) \xrightarrow{\Delta} H^2(M, \partial M; \nu). \]

The maps \( j^* \) and \( \Delta \) are dual to each other: for \( z_1 \in H^1(M; \nu) \) and \( z_2 \in H^1(\partial M; \nu) \),

\[ \langle j^*(z_1) \cup z_2, [\partial M] \rangle = \langle z_1 \cup \Delta(z_2), [M, \partial M] \rangle, \]

where \([M, \partial M] \in H_3(M, \partial M; R)\) and \([\partial M] \in H_2(\partial M; R)\) denote the respective fundamental classes. It follows that \( \dim \text{Im}(j^*) = \frac{1}{2} \dim H^1(\partial M; \nu) = k \). Moreover \( \Delta \circ j^* = 0 \) implies that \( \text{Im}(j^*) \) is isotropic and hence Lagrangian since \( \dim \text{Im}(j^*) = k \).

5.3 Corollary Let \( M \) be a cusped manifold, then \( \dim H^1(M; \nu_{Ad \rho_u}) \geq k \), \( \forall u \in U \subset C^k \).

Moreover \( M \) is infinitesimally projectively rigid iff \( \dim H^1(M; \nu_{Ad \rho_0}) = k \).

Proof. Follows directly from Lemma 5.2 and from the decomposition \( \mathfrak{sl}(4) = \mathfrak{so}(3,1) \oplus \nu \).
5.2 Parabolic representations

Let $\lambda$ and $\mu$ be two generators of $\mathbb{Z}^2$ and

$$\varrho: \mathbb{Z}^2 \to \text{PSO}(3, 1)$$

a representation into a parabolic group. Up to conjugation we suppose that the boundary point $[v_-]$ is the fixed point of the parabolic group. Viewing the parabolic group as translations of $\mathbb{R}^2$, $\varrho(\lambda)$ is a translation of vector $v_\lambda$, and $\varrho(\mu)$ of vector $v_\mu$. Assume that the representation has rank 2, (i.e. $v_\lambda$ and $v_\mu$ are linearly independent). Then:

5.4 Lemma If the angle $\varphi$ between $v_\lambda$ and $v_\mu$ is not in $\frac{\pi}{3}\mathbb{Z}$ then the map induced by restrictions

$$H^1(\mathbb{Z}^2; v_{\text{Ad}\varrho}) \xrightarrow{i_\lambda^* \oplus i_\mu^*} H^1(\lambda; v_{\text{Ad}\varrho}) \oplus H^1(\mu; v_{\text{Ad}\varrho})$$

is injective. Moreover, $\text{rank}(i_\lambda^*) = \text{rank}(i_\mu^*) = 1$.

Proof. We follow the notation from Subsection 4.3. We may assume that $v_\lambda = (1, 0)$, $v_\mu = (a \cos \varphi, a \sin \varphi) \in \mathbb{R}^2$, $a \sin \varphi \neq 0$. In the Heisenberg model $\mathcal{H}_-$, $\varrho(\lambda) = (1, 0, 0)$ and $\varrho(\mu) = (a \cos \varphi, a \sin \varphi, 0)$. For $\theta \in \mathbb{R}$, we define a representation $\varrho_\theta: \mathbb{Z} \oplus \mathbb{Z} \to G_-$ by

$$\varrho_\theta(\lambda) = \varrho(\lambda) \quad \text{and} \quad \varrho_\theta(\mu) = \varrho(\mu) \left( \begin{array}{cc} 1 & 0 \\ 0 & e^{i\theta} \end{array} \right).$$

Notice that $\varrho_\theta(\lambda)$ and $\varrho_\theta(\mu)$ commute, because $\left( \begin{array}{cc} 1 & 0 \\ 0 & e^{i\theta} \end{array} \right)$ fixes $(1, 0)$.

Differentiating at $\theta = 0$, we obtain an infinitesimal deformation i.e. a cocycle $d_\mu: \mathbb{Z}^2 \to g_- = g_0 \oplus g_{-1} \oplus g_{-2}$ given by

$$d_\mu(\gamma) = \frac{d\varrho_\theta(\gamma)}{d\theta} \bigg|_{\theta=0} \varrho_\theta(\gamma)^{-1}.$$ 

The cocycle $d_\mu: \mathbb{Z}^2 \to g_-$ is trivial when restricted to $\lambda$. More precisely we obtain

$$d_\mu(\lambda) = 0 \quad \text{and} \quad d_\mu(\mu) = \left( \begin{array}{cc} 0 & 0 \\ 0 & i \end{array} \right).$$

Notice that the derivative of the canonical embedding $U(2) \to \text{PSU}(3, 1)$ determinate by

$$A \mapsto \begin{pmatrix} A & 0 \\ 0 & I_2 \end{pmatrix}$$

is the map $u(2) \to \text{su}(3, 1)$ given by

$$a \mapsto \begin{pmatrix} a & 0 \\ 0 & 0 \end{pmatrix} - \frac{\text{tr} a}{4} I_4.$$
and that
\[
\begin{pmatrix}
0 & 0 \\
0 & 1
\end{pmatrix}
\mapsto
\frac{i}{4}
\begin{pmatrix}
-1 & 3 & -1 \\
3 & -1 & -1
\end{pmatrix}
\in iv.
\]

Hence we obtain a cocycle \( z_\mu : Z^2 \to \mathfrak{v} \) given by \( z_\mu (\lambda) = 0 \) and \( z_\mu (\mu) = a_\lambda \) where
\[
a_\lambda :=
\begin{pmatrix}
1 & 0 & 0 \\
0 & 0 & 0 \\
0 & 0 & 0
\end{pmatrix}
\in \mathfrak{v}.
\]

In the same way we obtain a second cocycle \( z_\lambda : Z^2 \to \mathfrak{v} \) given by \( z_\lambda (\lambda) = 0 \) and \( z_\lambda (\mu) = a_\mu \) where
\[
a_\mu :=
\begin{pmatrix}
1 & 0 & 0 \\
0 & 0 & 0 \\
0 & 0 & 0
\end{pmatrix}
\in \mathfrak{v}.
\]

Here \( \varphi \) is the angle between \( v_\mu \) and \( v_\lambda \). The matrix \( a_\mu \) is the analogue of \( a_\lambda \), as \( i a_\mu \) is an infinitesimal rotation in the direction perpendicular to \( v_\mu \), and of course it is invariant by \( g(\mu) \) (it can be obtained by conjugating \( a_\lambda \) by a rotation of angle \( \varphi \)).

We claim that the cocycle \( z_\mu \) is cohomologically nontrivial when restricted to \( \mu \), i.e. nontrivial in \( H^1(\mu; \mathfrak{v}_{Ad g}) \). This proves that \( z_\mu \) is a nontrivial cocycle, and \( \text{rank}(i_\mu^*) \geq 1 \). By symmetry of the generators, \( z_\lambda \) is a nontrivial cocycle and \( \text{rank}(i_\lambda^*) \geq 1 \). Moreover, since \( i_\mu^*(z_\lambda) = 0 = i_\lambda^*(z_\mu) \) it follows that the image of \( i_\mu^* \oplus i_\lambda^* \) is 2-dimensional and the assertion of the lemma follows.

To prove the claim, we will use the cup product
\[
H^1(\mu; \mathfrak{v}_{Ad g}) \times H^0(\mu; \mathfrak{v}_{Ad g}) \to H^1(\mu; \mathfrak{R}) \cong \mathfrak{R}
\]
associated to the Killing form defined in (4). Recall that \( a_\mu \in H^0(\mu; \mathfrak{v}_{Ad g}) = \mathfrak{v}^{Ad(\mu)} \) is invariant under the action of \( \mu \). The cup product \( i_\mu^*(z_\mu) \cup a_\mu \) is represented by the homomorphism \( H_1(\mu; \mathfrak{R}) \to \mathfrak{R} \) given by
\[
(i_\mu^*(z_\mu) \cup a_\mu)(\mu) = B(a_\lambda, a_\mu) = 8 \text{tr}(a_\lambda \cdot a_\mu)
\]
\[
= 32(1 + 2 \cos(2\varphi)) = 128(\cos^2(\varphi) - \frac{1}{4}).
\]

This is nonzero by the hypothesis about the angle \( \varphi \) between \( v_\lambda \) and \( v_\mu \), hence \( i_\mu^*(z_\mu) \cup a_\mu \) is not homologous to zero. \( \square \)
Notice that in the proof of Lemma 5.4, instead of the cup product we could have considered the Kronecker pairing between homology and cohomology, and we would have ended up checking the non-vanishing of the same evaluation of the Killing form $B(a_\lambda, a_\mu)$.

Before the next lemma, we still need a claim about symplectic forms on vector spaces.

**5.5 Claim** Let $(V, \omega)$ be a 2-dimensional symplectic subspace. Suppose that $f, g: V \to \mathbb{R}$ are linear forms which form a basis of the dual space $V^*$, i.e. $f \oplus g: V \to \mathbb{R}^2$ is an isomorphism.

Then there exists a constant $c \in \mathbb{R}$, $c \neq 0$, such that, for every $x, y \in V$

$$\omega(x, y) = c(f(x)g(y) - g(x)f(y)).$$

**Proof.** The claim is a consequence of the fact that the space of antisymmetric bilinear forms on $\mathbb{R}^2$ is one dimensional. \qed

**5.6 Lemma** If a subspace $L \subset H^1(\partial M; \mathfrak{v}_{Ad, \rho_0})$ is Lagrangian for the cup product, then there exist simple closed curves $\mu_1 \in \pi_1(\partial_1 M), \ldots, \mu_k \in \pi_1(\partial_k M)$ so that the image of $L$ injects in $H^1(\mu_1; \mathfrak{v}_{Ad, \rho_0}) \oplus \cdots \oplus H^1(\mu_k; \mathfrak{v}_{Ad, \rho_0})$. Moreover, injectivity fails if we consider only $k - 1$ curves.

**Proof.** Along this proof, the action on $\mathfrak{v}$ is the adjoint of the holonomy of the complete structure, so $Ad_{\rho_0}$ is omitted from notation. For $j = 1, \ldots, k$, let $res_j: H^1(\partial M; \mathfrak{v}) \to H^1(\partial_j M; \mathfrak{v})$ denote the map induced by restriction, which is also the projection to the $j$-th factor of the isomorphism

$$H^1(\partial M; \mathfrak{v}) \cong H^1(\partial_1 M; \mathfrak{v}) \perp \cdots \perp H^1(\partial_k M; \mathfrak{v}).$$

Recall that this is an orthogonal sum for the cup product (29).

We prove the lemma by induction on $k$. When $k = 1$, it suffices to chose two curves $\mu_1$ and $\lambda_1$ in $\partial_1 M$ that satisfy the hypothesis of Lemma 5.4

Hence

$$i_{\mu_1}^* \oplus i_{\lambda_1}^*: H^1(\partial_1 M; \mathfrak{v}) \to H^1(\mu_1; \mathfrak{v}) \oplus H^1(\lambda_1; \mathfrak{v})$$

is injective. Then for at least one of the curves, say $\mu_1$, $i_{\mu_1}^*(L) \neq 0$.

For the induction step, we chose the corresponding curves on the $k$-th component $\mu_k$ and $\lambda_k$, so that

$$i_{\mu_k}^* \oplus i_{\lambda_k}^*: H^1(\partial_k M; \mathfrak{v}) \to H^1(\mu_k; \mathfrak{v}) \oplus H^1(\lambda_k; \mathfrak{v})$$

is injective, and assume that $i_{\mu_k}^*(L) \neq 0$.

Let $L' \subset H^1(\partial_1 M; \mathfrak{v}) \perp \cdots \perp H^1(\partial_{k-1} M; \mathfrak{v})$ be the projection to the first $k - 1$ factors of the kernel of $i_{\mu_k}^*$ restricted to $L$; i.e.

$$L' = (res_1 \oplus \cdots \oplus res_{k-1})(\ker i_{\mu_k}^*|_L)$$

20
We first check that $L'$ is isotropic. Given $x, y \in L'$, there exist $x_k, y_k \in H^1(\partial_k M; v)$ such that $(x, x_k), (y, y_k) \in L$ and $i_{\mu_k}^*(x_k) = i_{\mu_k}^*(y_k) = 0$. Thus, by Claim 5.5 and equation (9):

$$0 = (x, x_k) \cup (y, y_k) = x \cup y + c_k(i_{\mu_k}^*(x_k)i_{\lambda_k}^*(y_k) - i_{\lambda_k}^*(x_k)i_{\mu_k}^*(y_k)) = x \cup y.$$

Finally we claim that the dimension of $L'$ is $k - 1$. Since $\dim(\ker(i_{\mu_k}^*|L)) = k - 1$, we need to check that $res_1 \oplus \cdots \oplus res_{k-1}$ restricted to $\ker i_{\mu_k}^*|L$ is injective. Let $x \in \ker(res_1) \cap \cdots \cap \ker(res_{k-1}) \cap \ker(i_{\mu_k}^*|L)$, we want to check that $x = 0$. Notice that $x \in H^1(\partial_k M; v) \cap L \cap \ker(i_{\mu_k}^*)$. Choose $y \in L$ such that $i_{\mu_k}^*(y) \neq 0$, this is possible because $i_{\mu_k}^*(L) \neq 0$. Then, using that $x \in H^1(\partial_k M; v)$, Claim 5.5 and Equation (9),

$$0 = x \cup y = c_k(i_{\mu_k}^*(x)i_{\lambda_k}^*(y) - i_{\lambda_k}^*(x)i_{\mu_k}^*(y)) = -c_k i_{\lambda_k}^*(x)i_{\mu_k}^*(y)$$

for some $c_k \neq 0$. Since $i_{\mu_k}^*(y) \neq 0$, $i_{\lambda_k}^*(x) = 0$. Therefore $x = 0$. \qed

6 The function on the deformation space

Recall that $M$ denotes a compact manifold with boundary a union of $k > 0$ tori and hyperbolic interior. The goal of this section is to give a sufficient cohomological condition which guarantees that infinitely many fillings on $M$ are infinitesimally rigid. For this we need several tools for constructing a function on the deformation space. The first one is given by the following lemma. All statements are up to taking a smaller neighborhood of $0$, $U \subset C^k$.

6.1 Lemma As in Section 2, let $U \subset C^k$ be an open neighborhood of $0$ which parametrizes the deformations of the complete holonomy of the interior of $M$.

1. There exists a nonvanishing element $a_u^1 \in v^{\rho_u(\pi_1(\partial, M))}$ that varies analytically in $u \in U$.

2. There exists a family of cohomology classes $\{z_u^1, \ldots, z_u^k\}$ that define a basis for the image of $H^1(M; v_{\Ad \rho_u}) \to H^1(\partial M; v_{\Ad \rho_u})$ and that varies analytically in $u \in U$.

6.2 Remark To vary analytically depends on the construction we take for cohomology, but we always think of an analytic map on a finite dimensional space of cocycles, either in simplicial cohomology (fixing a triangulation and varying the bundle) or in group cohomology (fixing a generating set for the fundamental group).
Proof. The first assertion follows directly from Lemma 5.1 (ii).

For the second part we will use Lemma 5.2 (ii). The rank of \( H^1(M; \mathfrak{v}_{\text{Ad} \rho_u}) \to H^1(\partial M; \mathfrak{v}_{\text{Ad} \rho_u}) \) is \( k \). Hence it suffices to take a basis when \( u = 0 \), \( \{ x_0^1, \ldots, x_0^k \} \) and then make it vary in the kernel of \( H^1(\partial M; \mathfrak{v}_{\text{Ad} \rho_u}) \to H^2(M, \partial M; \mathfrak{v}_{\text{Ad} \rho_u}) \), which is an analytic family of \( k \)-dimensional vector spaces. \( \square \)

For \( i = 1, \ldots, k \) we consider the following 1-cycle in the \( i \)-th torus \( \partial_i M \) of the boundary

\[
a_u^i \otimes \frac{1}{|p_i + q_i \tau_i|} (p_i \mu_i + q_i \lambda_i)
\]

in simplicial homology. This twisted cycle is the image of the untwisted cycle

\[
\frac{p_i \mu_i + q_i \lambda_i}{|p_i + q_i \tau_i|^2} \in H_1(\partial_i M, \mathbb{R})
\]

by the natural map

\[
H_1(\partial_i M, \mathbb{R}) \xrightarrow{a_u^i \otimes \cdot} H_1(\partial_i M, \mathfrak{v}_{\rho_u(\pi_1(\partial_i M))}) \to H_1(\partial_i M, \mathfrak{v})
\]

that consists in tensorizing by \( a_u^i \) and composing with the map induced by the inclusion of coefficients \( \mathfrak{v}_{\rho_u(\pi_1(\partial_i M))} \to \mathfrak{v} \).

Let \( \langle \ldots \rangle \) denote the Kronecker pairing between homology and cohomology. We define

\[
f(u) = \det \left( \langle z_u^i, a_u^j \otimes \frac{p_j \mu_j + q_j \lambda_j}{|p_j + q_j \tau_j|^2} \rangle_{ij} \right)
\]

where \( p_i \) and \( q_i \) are the generalized Dehn filling coefficients corresponding to \( u \in U \) (see Section 2). If we view \( z_u \) as a map on simplicial chains taking values on \( \mathfrak{v} \), and \( B \) denotes the Killing form, then

\[
f(u) = \det \left( B(z_u^i \frac{p_j \mu_j + q_j \lambda_j}{|p_j + q_j \tau_j|^2}, a_u^j) \right).
\]

6.3 Remark The function \( f \) depends on several non-canonical choices. But we are only interested in the zero locus of \( f \) and this set does not depend on the different cocycles involved in the definition of \( f \). Notice also that Lemma 2.2 implies that \( f \) is analytic and \( f(0) = 0 \). Proposition 1.8 below shows that the zero locus \( f^{-1}(\{0\}) \) of \( f \) might be one dimensional and that in general \( 0 \in f^{-1}(\{0\}) \) is not isolated point (see Section 8.2).

In the sequel let \( u(p,q) \) denote the parameter of the structure whose completion gives the Dehn filling with coefficients \( (p_1, q_1), \ldots, (p_k, q_k) \) where \( (p_i, q_i) \) are pairs of coprime integers.

6.4 Lemma If
(i) \( f(u_{(p,q)}) \neq 0 \) and
(ii) \( \dim H^1(M, v_{\text{Ad} \rho_{u_{(p,q)}}}) = k \),

then \( H^1(M_{(p,q)}, v_{\text{Ad} \rho_{u_{(p,q)}}}) = 0 \).

**Proof.** In this proof the representation \( \rho_{u_{(p,q)}} \) is fixed and we remove \( \text{Ad} \rho_u \) from notation.

Hypothesis (i) and (ii) imply that
\[
\{ a_1^u \otimes (p_1 \mu_1 + q_1 \lambda_1), \ldots, a_k^u \otimes (p_k \mu_k + q_k \lambda_k) \}
\]
is a basis for \( H_1(M; v) \). Hence for \( \gamma := \gamma_1 \cup \cdots \cup \gamma_k, \gamma_i = p_i \mu_i + q_i \lambda_i \), the following composition gives an isomorphism in homology:
\[
\bigoplus_{i=1}^k H_1(\gamma_i; R) \rightarrow \bigoplus_{i=1}^k H_1(\gamma_i; v_{\rho_{u_{(\partial_i M)}}}) \rightarrow H_1(\gamma; v) \rightarrow H_1(M; v).
\]

Equivalently, we have an isomorphism in cohomology:
\[
H^1(M; v) \rightarrow H^1(\gamma; v) \rightarrow \bigoplus_{i=1}^k H^1(\gamma_i; v_{\rho_{u_{(\partial_i M)}}}) \rightarrow \bigoplus_{i=1}^k H^1(\gamma_i; R). \tag{10}
\]

Let \( N \) denote a tubular neighborhood of the filling geodesics, so that \( N = N_1 \cup \cdots \cup N_k \) is the union of \( k \) solid tori, \( N \cup M \) is the closed manifold \( M_{(p,q)} \) and \( N \cap M = \partial M \). We claim that the inclusions induce an isomorphism
\[
H^i(M; v) \oplus H^i(N; v) \rightarrow H^i(\partial M; v)
\]
for \( i = 0 \) and \( i = 1 \). Then by Mayer-Vietoris, \( H^1(M_{(p,q)}, v) = 0 \) follows.

Let us check the claim. When \( i = 0 \), \( H^0(M; v) \cong v_{\text{Ad} \rho_{u_{(\partial_i M)}}} = 0 \), and the required isomorphism comes from the fact that \( \pi_1(N_j) \) and \( \pi_1(\partial_j M) \) have the same image under \( \rho_u \) and hence the same invariant subspace.

When \( i = 1 \), we notice that by Lemma 5.2
\[
H^1(\partial_i M, v) = H^1(\partial_i M, R) \otimes v_{\rho_{u_{(\partial_i M)}}},
\]
and \( \dim v_{\rho_{u_{(\partial_i M)}}} = 1 \), by Lemma 5.1. Similarly,
\[
H^1(N_i, v) = H^1(N_i, R) \otimes v_{\rho_{u_{(\partial_i M)}}}.
\]

Then the proof follows from isomorphism (10) and the natural isomorphism induced by inclusions:
\[
H^1(\partial_i M; R) \cong H^1(N_i; R) \oplus H^1(\gamma_i; R).
\]
\[\square\]
6.5 Corollary If the generic dimension of $H^1(M; v_{\text{Ad} \rho_u})$ is $k$ and if $f$ is non-constant in a neighborhood of 0, then infinitely many Dehn fillings are infinitesimally rigid.

Proof. The dimension of $H^1(M; v_{\text{Ad} \rho_u})$ is bounded below by $k$ and lower semicontinuous on $u \in U$ (it is larger on a proper analytic subset). Hence the set of $u \in U$ where $\dim H^1(M; v_{\text{Ad} \rho_u}) \neq k$ or $f(u) = 0$ is a proper analytic subset of $U$, and it misses infinitely many Dehn fillings by Lemma 4.4.

For a collection of simple closed curves $\mu = \{\mu_1, \ldots, \mu_k\}$, where $\mu_i \subset \partial_i M$ is non-trivial in homology, let $\rho_{\alpha_i}$ denote the holonomy of the corresponding hyperbolic cone structure with cone angle $\alpha$ and meridians $\mu$.

6.6 Proposition Assume that there exists a collection of simple closed curves as above $\mu \subset \pi_1(\partial M)$ and some $\varepsilon > 0$ so that, $\forall 0 < \alpha < \varepsilon$,

$$\dim H^1(M, \mu; v_{\text{Ad} \rho_{\alpha_i}}) = 3k.$$ Then infinitely many Dehn fillings are infinitesimally rigid.

Proof. Our goal is to prove the proposition by applying Corollary 6.5. Since $\rho_{\alpha_i}(\mu_j)$ is a rotation of angle $0 < \alpha < \pi$, by Lemma 4.2 $\dim H^0(\mu_j; v_{\text{Ad} \rho_{\alpha_i}}) = \dim v_{\text{Ad} \rho_{\alpha_i}}(\mu_j) = 3$, and therefore $\dim H^0(\mu; v_{\text{Ad} \rho_{\alpha_i}}) = 3k$.

Then the long exact sequence of the pair $(M, \mu)$ starts as follows:

$$0 \to H^0(\mu, v_{\text{Ad} \rho_{\alpha_i}}) \to H^1(M, \mu, v_{\text{Ad} \rho_{\alpha_i}}) \to H^1(M, v_{\text{Ad} \rho_{\alpha_i}}) \to \cdots.$$ Since $\dim H^0(\mu; v_{\text{Ad} \rho_{\alpha_i}}) = \dim H^1(M, \mu, v_{\text{Ad} \rho_{\alpha_i}})$, we have an inclusion

$$0 \to H^1(M; v_{\text{Ad} \rho_{\alpha_i}}) \to H^1(\mu; v_{\text{Ad} \rho_{\alpha_i}}).$$

The inclusion of $\mu$ in $M$ factors through $\partial M$, hence by Lemma 5.2 it follows that

$$\dim H^1(M; v_{\text{Ad} \rho_{\alpha_i}}) = k,$$

which is the first condition for applying Corollary 6.5, by lower semicontinuity of the dimension of $H^1$.

Moreover, using Lemma 5.2 (i), it follows that

$$H^1(M; v_{\text{Ad} \rho_{\alpha_i}}) \cong \bigoplus_{j=1}^k H^1(\mu_j; R) \otimes v_{\rho_{\alpha_i}(\pi_1(\partial_j M))}.$$
This implies that one can choose a basis \( \{ z^1_u, \ldots, z^k_u \} \) for \( H^1(M; v_{Ad\rho,\alpha}) \), where \( z^i_u = \hat{\mu}_j \otimes a^j_{\alpha_1} \) and \( \hat{\mu}_j \in H^1(\mu_j; \mathbb{Z}) \) is the dual of the fundamental class in \( H_1(\mu_j; \mathbb{Z}) \). Thus, since \( p_j = 2\pi/\alpha \) and \( q_j = 0 \), we get

\[
f(\alpha_i) = \frac{\alpha^k}{(2\pi)^k} B(a^1_{\alpha_1}, a^1_{\alpha_1}) \cdots B(a^k_{\alpha_1}, a^k_{\alpha_1}) \neq 0,
\]

as the Killing form on \( v_{Ad\rho,\pi(\partial_1, M)} \) is nondegenerate.

**Proof of Theorem 1.4.** As \( M \) is infinitesimally projectively rigid, by Lemma 5.6 we can choose a set of slopes \( \mu = \mu_1 \cup \cdots \cup \mu_k \), so that

\[
0 \to H^1(M; v_{Ad\rho_0}) \to H^1(\mu; v_{Ad\rho_0})
\]

is exact. By the long exact sequence of the pair \( (M, \mu) \), since \( \dim v_{Ad\rho_0}(\mu_j) = 3 \), this is equivalent to saying that \( \dim H^1(M, \mu; v_{Ad\rho_0}) = 3k \). By analyticity and lower semicontinuity of the dimension of the cohomology, the hypothesis of Proposition 6.6 holds true.

**Proof of Theorem 1.5.** Let \( M(p, q) \) be infinitesimally projectively rigid. Then \( u(p, q) \in U \) denotes the parameter in the Thurston slice corresponding to the holonomy of the structure on \( M \) induced by the Dehn filling.

As in the proof of Lemma 6.4, a Mayer-Vietoris argument gives that

\[
\dim H^1(M; v_{Ad\rho_0(p, q)}) = k.
\]

Moreover, if the parameter \( u(p, q) \) is contained in the domain of definition of \( f \) then \( f(u(p, q)) \neq 0 \). A priori the domain of definition of \( f \) could be a smaller neighborhood of the origin: the problem is that the cohomology classes \( z^1_u, \ldots, z^k_u \in \text{Im}(H^1(M; v_{Ad\rho}) \to H^1(\partial M; Ad\rho)) \) could be linearly dependent or even not be defined outside a small neighborhood of 0. To fix that, we use the path of hyperbolic cone structures, that gives a segment in \( U \), that we parametrize by the cone angle \( \alpha \in [0, 2\pi] \). Let \( \alpha_\alpha \in U \) denote the parameter of the deformation space and \( \gamma_1, \ldots, \gamma_k \) the boundary slopes. By compactness, the segment \( [0, 2\pi] \) is covered by intervals \((\alpha_\alpha, \alpha_{\alpha+1})\) where there exists cohomology classes \( z^1_\alpha, \ldots, z^k_\alpha \in \text{Im}(H^1(M; v_{Ad\rho}) \to H^1(\partial M; Ad\rho)) \) that vary analytically on \( \alpha \) and are linearly independent for each \( \alpha \in (\alpha_\alpha, \alpha_{\alpha+1}) \), by Lemma 6.1. On each interval we may use the cohomology classes to construct functions similar to \( f \), i.e. as the determinant of the matrix of Kronecker pairings between \( z^i_\alpha \) and the homology class represented by \( a^i_{\alpha_1} \otimes \frac{\alpha}{2\pi} \gamma_j \). This finite sequence of paths and the usual analyticity argument gives that in a neighborhood of 0, \( f \neq 0 \) and the generic dimension of the cohomology is the expected one. Hence we may apply Corollary 6.5.

\( \square \)
7 Flexing slopes

7.1 Definition Let $M^3$ be a cusped hyperbolic manifold of finite volume which is infinitesimally projectively rigid. Let $\gamma$ be a slope of $\partial_1 M$. We say that $\gamma$ is a flexing slope if the map

$$i_\gamma^*: H^1(M; v_{Ad\rho_0}) \to H^1(\gamma; v_{Ad\rho_0})$$

is nontrivial.

7.2 Proposition Let $M^3$ be a cusped hyperbolic manifold of finite volume which is infinitesimally projectively rigid and let $\mu, \lambda \in \partial_1 M$ be a pair of simple closed curves generating the fundamental group of $\partial_1 M$. Let $(p_n, q_n) \in \mathbb{Z}^2$ be a sequence of coprime integers lying on a line $ap_n + bq_n = c$. If $\gamma = -b\mu + a\lambda$ is a flexing slope, then $M^3_{(p_n, q_n), \infty, \cdots, \infty}$ is infinitesimally rigid for $n$ large enough.

Proof. After changing the basis in homology, the curves $\mu$ and $\lambda$ are chosen such that $a = 1, b = 0$, i.e. $\lambda = (0, 1)$ is the flexing slope. We also may assume $(p_n, q_n) = (c, n)$.

Let us consider the path

$$s \mapsto \begin{cases} (c, \frac{1}{s}) & \text{if } s \neq 0 \\ \infty & \text{if } s = 0 \end{cases}$$

in the parameter space. Denote by $u(s)$ the corresponding point in the deformation space.

7.3 Lemma The path $u(s)$ is a real analytic on $s \in (-\varepsilon, \varepsilon)$.

Proof. Setting $\tau(u) = v(u)/u$, from $pu + qv = u(c + \frac{1}{s}\tau(u)) = 2\pi i$ we can write

$$u(s(c + \tau(u))) = s2\pi i.$$ 

Since $\tau(0) \neq 0$ and $\tau$ is analytic on $u$, this allows to define $u$ as analytic function on $s$, by applying the analytic version of the implicit function theorem. \hfill \Box

Let $\theta_u \in \text{Im}(H^1(M; v_{Ad\rho_u}) \to H^1(\partial_1 M; v_{Ad\rho_u}))$ be an analytic family of cohomology classes, so that $i_\lambda^*(\theta_0) \neq 0$. This is always possible since $i_\lambda^*$ factors through $H^1(\partial_1 M; v_{Ad\rho_u})$.

The two cohomology classes $z_\mu, z_\lambda \in H^1(\partial_1 M; v_{Ad\rho_0})$ as defined in the proof of Lemma 4 satisfy $i_\mu^*(z_\lambda) = i_\lambda^*(z_\mu) = 0$, $i_\mu^*(z_\mu) \neq 0$, and $i_\lambda^*(z_\lambda) \neq 0$. Hence we may assume that

$$\theta_0 = z_\lambda + \beta z_\mu, \quad \text{for some } \beta \in \mathbb{R}.$$
Let also \( a_u(s) \in V^{Ad, \rho_u(s)}(\pi_1(M)) \) be an analytic family of invariant elements, with \( a_0 \neq 0 \). As in Lemma 6.1, we want to see that for \( s > 0 \), the following function does not vanish:

\[
\begin{align*}
f(s) &:= \langle \theta_u(s), a_u(s) \rangle \left( \frac{c\mu + \frac{1}{2}s\lambda}{c + \frac{1}{2}s\tau} \right)^2 \\
&= \frac{s}{|s c + \tau|^2} \langle \theta_u(s)(s c\mu + \lambda), a_u(s) \rangle.
\end{align*}
\]

Notice that it follows from the proof of Lemma 5.1 that for small \( s \), \( s \neq 0 \), the restriction of the Killing form on the subspace \( V^{Ad, \rho_u(s)}(\pi_1(M)) \) is positive definite i.e. \( B(a_u(s), a_u(s)) > 0 \) for sufficiently small \( s \neq 0 \).

7.4 Lemma If \( \|a_u(s)\| = B(a_u(s), a_u(s))^{1/2} \), then

\[
\lim_{s \to 0} \frac{B(\theta_u(s)(\lambda), a_u(s))}{\|a_u(s)\|} = 16 \quad \text{and} \quad \lim_{s \to 0} \frac{B(\theta_u(s)(\mu), a_u(s))}{\|a_u(s)\|} = 16\beta.
\]

Assuming the lemma we obtain

\[
\frac{f(s)}{s \|a_u(s)\|} = \frac{1}{|s c + \tau|^2} \left( \frac{B(\theta_u(s)(\lambda), a_u(s))}{\|a_u(s)\|} + s c \frac{B(\theta_u(s)(\mu), a_u(s))}{\|a_u(s)\|} \right)
\]

and hence

\[
\lim_{s \to 0} \frac{f(s)}{s \|a_u(s)\|} = \frac{16}{|\tau_0|^2}.
\]

Hence \( f(s) \neq 0 \) for \( s \neq 0 \). Moreover, since the dimension of \( H^1(M; V_{Ad\rho_u}) \) is lower semicontinuous, it still satisfies \( \dim(H^1(M; V_{Ad\rho_u})) = k \). By analyticity those conditions are satisfied for all but finitely many \( s \), hence we may apply Lemma 6.4.

This concludes the proof of Proposition 7.2 assuming Lemma 7.4. \( \square \)

Before proving Lemma 7.4 we still need a further computation. Let \( w_0 \in \mathfrak{su}(3, 1) \) denote

\[
w_0 = \frac{i}{2}V_0, \quad \text{where} \quad V_0 = \begin{pmatrix} 1 & 1 \\ -1 & -1 \end{pmatrix}.
\]

Note that \( w_0 \) is contained in \( \mathfrak{g}_0 \subset \mathfrak{su}(3, 1) \) which is the Lie algebra of the stabilizer of \( [v_\pm] \in \partial_\infty H^*_C \).

7.5 Lemma The invariant element \( a_u \in V^{\rho_u(\pi_1(M))} \) can be chosen such that:

\[
a_u = p(u) + 4 \left( \sinh^2 \frac{u}{2} \right) V_0
\]

where \( p(u) \) is an infinitesimal parabolic transformation.

27
Proof. Since $w_0$ is invariant by the stabilizer $G_0$ for $u \neq 0$, $a_u$ can be obtained by conjugating $w_0$, and then by normalizing the result so that the limit exists if $u$ tends to 0.

Recall that in the Heisenberg model the subgroup of real parabolic representations corresponds to $\mathbb{R}^2 \times \{0\} \subset \mathcal{H}_- \subset G_- = \mathcal{H}_- \rtimes (U(2) \times \mathbb{R})$. Note also that $w_0$ is the image of $iI_2$ under the canonical inclusion $u(2) \hookrightarrow \mathfrak{su}(3,1)$.

Suppose that $(x, y, 0) \in \mathbb{R}^2 \times \{0\}$ is the second fixed point of $\rho_u(\pi_1 \partial M)$. In the notation of $\text{PSL}_2(\mathbb{C})$ we have

$$\rho_u(\mu) = \pm \begin{pmatrix} e^{u/2} & 1 \\ 0 & e^{-u/2} \end{pmatrix},$$

hence

$$x + iy = -\frac{1}{2 \sinh(u/2)}.$$

Using the formalism of $G_-$, the conjugate of $w_0$ we are looking for is:

$$\text{Ad}_{(x,y,0)} \begin{pmatrix} 1 & 0 \\ 0 & i \end{pmatrix} = \frac{d}{dt}(x, y, 0) \begin{pmatrix} e^u & 0 \\ 0 & e^{-u} \end{pmatrix} (-x, -y, 0) \bigg|_{t=0} = \frac{d}{dt}(x, y, 0) (-xe^u, -ye^u, 0) \begin{pmatrix} e^u & 0 \\ 0 & e^{-u} \end{pmatrix} \bigg|_{t=0} = \frac{d}{dt}(x(1 - e^u), y(1 - e^u), (x^2 + y^2) \sin(t)) \begin{pmatrix} e^u & 0 \\ 0 & e^{-u} \end{pmatrix} \bigg|_{t=0} = (\begin{pmatrix} -ix & -iy, (x^2 + y^2) \end{pmatrix} + \begin{pmatrix} i & 0 \\ 0 & i \end{pmatrix}).$$

Under the inclusion $g_- \hookrightarrow \mathfrak{su}(3,1)$ this element is written as

$$\begin{pmatrix} \frac{i}{2} & \frac{i}{2} \\ -\frac{i}{2} & -\frac{i}{2} \end{pmatrix} - i \begin{pmatrix} 0 & 0 & x & y \\ 0 & 0 & x & y \\ -x & x & 0 & 0 \\ -y & y & 0 & 0 \end{pmatrix} + i(x^2 + y^2) \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & -1 \\ 0 & 0 & 1 & -1 \end{pmatrix}.$$

Hence $\text{Ad}_{(x,y,0)}(w_0) = w_0 + \text{Parabolic}$.

Now $x^2 + y^2 = \frac{1}{4 \sinh^2(u/2)}$ and in order to obtain an invariant matrix which converges when $u \to 0$ we take

$$a_u = -4i \left(\sinh^2\frac{u}{2}\right) \text{Ad}_{(x,y,0)}(w_0) = 4 \left(\sinh^2\frac{u}{2}\right) V_0 + \text{Parabolic}$$

and the lemma is clear. □

Proof of Lemma 7.4 Using Lemmas 7.3 and 3.3 we obtain:

$$B(a_u, a_u)^{1/2} = 4 \sinh^2\frac{u}{2} B(V_0, V_0)^{1/2} = 8 \sinh^2\frac{u}{2},$$

$$B(\theta_u(s)(\lambda), a_u(s)) = B(\theta_u(s)(\lambda), V_0) 4 \sinh^2\frac{u}{2}.$$
Hence
\[
\frac{B(\theta_{u(s)}(\lambda), a_{u(s)})}{\|a_{u(s)}\|} = \frac{1}{2} B(\theta_{u(s)}(\lambda), V_0) \rightarrow \frac{1}{2} B(\theta_{u(0)}(\lambda), V_0) \text{ as } s \rightarrow 0,
\]
and
\[
B(\theta_{u(0)}(\lambda), V_0) = B(z_\lambda(\lambda), V_0) = B(a_\mu, W_0) = 32.
\]
A similar computation holds for \(\theta_{u(s)}(\mu)\).

8 Examples

In this section we compute two examples, the figure eight knot and the Whitehead link exteriors. We start introducing some notation. Let \(x \in \mathbb{R}^4\) be a column vector. As in Section 3.3 we will use the following notation:
\[
x^* = x^t J.
\]
Then for all \(x, y \in \mathbb{R}^4\) we have that
\[
xy^* + yx^* \in v.
\]
In the sequel we will make use of the following basis \(\{v_1, \ldots, v_9\}\) of \(v\):
\[
v_i = e_i e_i^* + e_4 e_4^* \quad \text{for } i = 1, \ldots, 3,
\]
and
\[
v_4 = e_1 e_1^* + e_2 e_2^*, \quad v_5 = e_1 e_3^* + e_3 e_1^*, \quad v_6 = e_1 e_4^* + e_4 e_1^*,
\]
\[
v_7 = e_2 e_3^* + e_3 e_2^*, \quad v_8 = e_2 e_4^* + e_4 e_2^*, \quad v_9 = e_3 e_3^* + e_4 e_3^*.
\]

8.1 The figure eight knot

In this section we explain the computations to show that the figure eight knot exterior is infinitesimally projectively rigid.

Let \(\Gamma\) be the fundamental group of the figure eight knot exterior. We fix a presentation of \(\Gamma\):
\[
\Gamma = \langle x, y \mid xy^{-1}x^{-1}yxy^{-1}xy^{-1}x^{-1}y^{-1} \rangle. \quad (11)
\]
where \(x\) and \(y\) represent meridians.

By Corollary 5.3 it suffices to show that \(\dim H^1(\Gamma, v_{Ad \rho_0}) = 1\).

We start with a holonomy representation of the complete structure in \(SL_2(\mathbb{C})\) [27]:
\[
x \mapsto \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}, \quad y \mapsto \begin{pmatrix} 1 & 0 \\ 1 - i \sqrt{3} \\ 0 \end{pmatrix},
\]

Using for instance the construction described in [9], the representation in \(PSO(3,1)\) is given by:
\[
\rho_0(x) = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & -1 & 1 \\ 0 & 1 & 1/2 & 1/2 \\ 0 & 1 & -1/2 & 3/2 \end{pmatrix}, \quad \rho_0(y) = \begin{pmatrix} 1 & 0 & \sqrt{3}/2 & \sqrt{3}/2 \\ 0 & 1 & 1/2 & 1/2 \\ -\sqrt{3}/2 & -1/2 & 1/2 & -1/2 \\ \sqrt{3}/2 & 1/2 & 1/2 & 3/2 \end{pmatrix}.
\]

29
Notice that the holonomy of $x$ and $y$ have a fixed point in the light cone, which are respectively:

$$v_+ = \begin{pmatrix} 0 \\ 1 \\ 1 \end{pmatrix} \quad \text{and} \quad v_- = \begin{pmatrix} 0 \\ -1 \\ 1 \end{pmatrix}.$$  

With respect to the basis $\{v_1, \ldots, v_9\}$ for $\mathfrak{v}$ the adjoint representation is given by:

$$\text{Ad} \, \rho_0(x) = 
\begin{pmatrix}
1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
1 & 2 & 2 & 0 & 0 & 0 & -2 & 2 & -2 \\
\frac{1}{4} & \frac{5}{4} & \frac{1}{2} & 0 & 0 & 0 & 1 & 1 & \frac{1}{2} \\
0 & 0 & 0 & 1 & -1 & -1 & 0 & 0 & 0 \\
0 & 0 & 0 & 1 & -\frac{1}{2} & -\frac{1}{2} & 0 & 0 & 0 \\
0 & 0 & 0 & -1 & \frac{1}{2} & \frac{3}{2} & 0 & 0 & 0 \\
\frac{3}{2} & \frac{5}{2} & 2 & 0 & 0 & 0 & -\frac{3}{2} & \frac{5}{2} & -2 \\
\frac{1}{2} & 0 & 0 & 0 & 0 & 0 & 2 & \frac{1}{2} & 0 \\
\end{pmatrix}.$$

and

$$\text{Ad} \, \rho_0(y) = 
\begin{pmatrix}
\frac{7}{4} & \frac{3}{4} & \frac{3}{2} & 0 & \sqrt{3} & -\sqrt{3} & 0 & 0 & \frac{3}{2} \\
\frac{1}{4} & \frac{3}{4} & \frac{1}{2} & 0 & 0 & 0 & 1 & 1 & \frac{1}{2} \\
\frac{\sqrt{3}}{4} & \frac{\sqrt{3}}{4} & \frac{\sqrt{3}}{2} & 1 & 1/2 & -1/2 & \sqrt{3} & \sqrt{3} & \sqrt{3} \\
-\frac{\sqrt{3}}{4} & -\frac{\sqrt{3}}{4} & -\sqrt{3} & 0 & -\frac{1}{2} & -\frac{1}{4} & \frac{1}{2} & -\frac{1}{2} & 0 \\
-\frac{\sqrt{3}}{4} & -\frac{\sqrt{3}}{4} & -\sqrt{3} & 0 & -\frac{1}{2} & -\frac{1}{4} & \frac{1}{2} & -\frac{1}{2} & 0 \\
-\frac{1}{2} & \frac{1}{2} & 0 & \frac{\sqrt{3}}{4} & \frac{\sqrt{3}}{4} & \frac{1}{4} & -\frac{1}{2} & 0 \\
\frac{3}{4} & \frac{5}{4} & 1 & \frac{\sqrt{3}}{4} & \frac{\sqrt{3}}{4} & -\frac{1}{4} & \frac{1}{2} & 1 \\
-\frac{3}{2} & -1 & -\frac{1}{2} & -\frac{\sqrt{3}}{2} & 0 & \sqrt{3} & 0 & -1 & \frac{1}{2} \\
\end{pmatrix}.$$
isomorphism of $\mathbf{R}$-vector spaces:
\[
Z^1 \leftrightarrow \{(a, b) \in \mathfrak{v}^2 \mid \frac{\partial w}{\partial x} \cdot a + \frac{\partial w}{\partial y} \cdot b = 0\},
\]
where $w = x y^{-1} x^{-1} y x y^{-1} y^{-1}$ is the relation in the presentation of $\Gamma$, and $\frac{\partial w}{\partial x}, \frac{\partial w}{\partial y}$ stand for the Fox derivatives [22]:
\[
\frac{\partial w}{\partial x} = 1 - x y^{-1} x^{-1} + x y^{-1} x^{-1} y + y x y^{-1} x^{-1} - y,
\]
\[
\frac{\partial w}{\partial y} = -x y^{-1} + x y^{-1} x^{-1} - y x y^{-1} x^{-1} + y x y^{-1} - 1.
\]
Thus, $Z^1$ is isomorphic to the kernel of the linear map from $\mathfrak{v} \times \mathfrak{v}$ to $\mathfrak{v}$ with matrix:
\[
\left( \text{Ad}_{\rho_0}(\frac{\partial w}{\partial x}), \text{Ad}_{\rho_0}(\frac{\partial w}{\partial y}) \right).
\]
One can check that this matrix has rank 8, by means of an elementary but tedious computation. Hence $\dim Z^1 = 10$, as claimed.

To prove Proposition 1.7 we need to show:

8.1 Remark The longitude is a flexing slope.

With this remark, Proposition 1.7 is just an application of Proposition 7.2. To prove that the longitude is a flexing slope, we need to analyze more carefully the previous computation.

By looking at the kernel of matrix (12), we choose one cocycle $d$ determined by:
\[
d(x) = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & -3 & -1 \\ 0 & -3 & 0 & 0 \\ 0 & 1 & 0 & 0 \end{pmatrix}
\]
and $d(y) = 0$.

Let $l = y x^{-1} y^{-1} x^2 y^{-1} x^{-1} y$ be the longitude that commutes with $x$. Then, by Fox calculus,
\[
d(l) = \begin{pmatrix} 60 & -4 \sqrt{3} & 60 \sqrt{3} & -68 \sqrt{3} \\ -4 \sqrt{3} & -4 & -4 & 12 \\ 60 \sqrt{3} & -12 & 178 & -206 \\ 68 \sqrt{3} & -12 & 206 & -234 \end{pmatrix}.
\]
To see that $d$ restricted to $l$ is nontrivial, following the proof of Lemma 5.4 we must find an invariant element $a \in \mathfrak{v}^{\text{Ad}_{\rho_0}(l)}$ such that $B(d(l), a) \neq 0$. Since:
\[
\rho_0(l) = \begin{pmatrix} 1 & 0 & -2 \sqrt{3} & 2 \sqrt{3} \\ 0 & 1 & 0 & 0 \\ 2 \sqrt{3} & 0 & -5 & 6 \\ 2 \sqrt{3} & 0 & -6 & 7 \end{pmatrix},
\]

31
following again the proof of Lemma 5.4, we choose

$$a = \begin{pmatrix} -1 & 3 \\ -1 & -1 \end{pmatrix},$$

and we have that $B(d(l), a) = -16 \neq 0$.

### 8.2 Orbifolds with branching locus the figure eight knot

Let $O_n$ denote the orbifold with underlying space $S^3$, branching locus $\text{Sing}(O_n)$ the figure eight knot and ramification index $n$. The orbifold $O_n$ is hyperbolic for $n \geq 4$. Note that the orbifold $O_n$ has a finite cyclic covering $\tilde{O}_n \to O_n$ where $M_n := \tilde{O}_n$ is the so called Fibonacci manifold which is widely studied in the literature [14].

The aim of this subsection is to prove Proposition 1.8, which states that $O_n$ is not locally projectively rigid for sufficiently large $n$, and that its deformation space is a curve.

As before, $\Gamma_0 := \Gamma = \pi_1(O_n \setminus \text{Sing}(O_n))$ denotes the fundamental group of the figure eight knot exterior, so that

$$\Gamma_1/n := \pi_1^{\text{orb}}(O_n) \cong \Gamma/\langle m^n \rangle,$$

for $m \in \Gamma$ representing a meridian. Note that there exists an exact sequence

$$0 \to \pi_1(M_n) \to \pi_1^{\text{orb}}(O_n) \to \mathbb{Z}/n\mathbb{Z} \to 0.$$

The figure eight knot is amphicheiral and hence there exists an automorphism of $\Gamma_0$ preserving the longitude and sending the meridian to its inverse. Such an automorphism $\varphi_0: \Gamma_0 \to \Gamma_0$ is given by

$$\varphi_0(x) = x^{-1} \text{ and } \varphi_0(y) = yx^{-1}y^{-1}x^{-1}y^{-1}.$$  By direct calculation using Presentation (11) and the meridian/longitude pair $m = x$ and $l = yx^{-1}y^{-1}x^2y^{-1}x^{-1}y$, one checks that $\varphi_0$ is an automorphism and that

$$\varphi_0(m) = m^{-1} \text{ and } \varphi_0(l) = l.$$  Hence $\varphi_0$ induces automorphisms

$$\varphi_{1/n}: \Gamma_{1/n} \to \Gamma_{1/n}.$$

Let $\rho_0: \Gamma_0 \to PSO(3, 1)$ and $\rho_{1/n}: \Gamma_{1/n} \to PSO(3, 1)$ denote the holonomy representations. Then by Mostow–Prasad rigidity there exists a unique element $A_{1/n} \in PSO(3, 1)$ such that

$$\rho_{1/n} \circ \varphi_{1/n} = \text{Ad}_{A_{1/n}} \circ \rho_{1/n} \quad (13)$$
for \( n \geq 4 \), including \( 0 = 1/\infty \).

For any group homomorphism \( \varphi : \Gamma \to \Gamma' \) and any \( \Gamma' \)-module \( a' \) we denote by \( \varphi' a' \) the \( \Gamma \)-module with underlying set \( a' \) and the \( \Gamma \) action \( \gamma \circ a' = \varphi(\gamma) \circ a' \). It is easy to check that \( \varphi \) induces a map

\[
 f^*: H^*(\Gamma', a') \to H^*(\Gamma, \varphi' a')
\]

(see [6, III.8]). Now any \( \Gamma \)-module \( a \) and any morphism of \( \Gamma \)-modules \( \alpha : \varphi a' \to a \) there is an induced map in cohomology \( (\varphi, \alpha)^*: H^*(\Gamma, a) \to H^*(\Gamma, a') \).

Now Equation (13) tells us that \( \text{Ad}_{A_{1/n}^{-1}} : \varphi_{1/n} \to v_{\rho_{1/n}} \) is a \( \Gamma_{1/n} \)-module morphism and hence there is a induced map

\[
 \varphi^*_{1/n} := (\varphi_{1/n}, \text{Ad}_{A_{1/n}^{-1}})^*: H^1(\Gamma_{1/n}, v_{\rho_{1/n}}) \to H^1(\Gamma_{1/n}, v_{\rho_{1/n}})
\]

given by \( \varphi^*_{1/n}(z) = \text{Ad}_{A_{1/n}^{-1}} \circ \varphi_{1/n} \).

In the sequel we shall compute the action of \( \varphi^*_{1/n} \) first on the homology \( H^*(\partial M, v_{\rho_{1/n}}) \) and then we shall deduce its action on \( H^*(\Gamma_{1/n}, v_{\rho_{1/n}}) \).

For \( 4 \leq n < \infty \), we have a natural isomorphism

\[
 H^*(\partial M, v_{\rho_{1/n}}) \cong H^*(\partial M, R) \otimes v^{\rho_{1/n}}(\pi_{1,\partial M})
\]

(see Lemma 5.2). For \( n = \infty \) Lemma 5.4 applies and hence

\[
 i^*_l \oplus i^*_m : H^1(\partial M, v_{\rho_0}) \to H^1(l, v_{\rho_0}) \oplus H^*(m, v_{\rho_0})
\]

is injective. Moreover \( \text{rk}(i^*_l) = \text{rk}(i^*_m) = 1 \).

In the sequel let \( \varphi^* : H^*(\partial M, R) \to H^*(\partial M, R) \) denote the the map induced in the untwisted cohomology with real coefficients.

**8.2 Lemma** For \( n < \infty \), with respect to the isomorphism \( H^*(\partial M, v_{\rho_{1/n}}) \cong H^*(\partial M, R) \otimes v^{\rho_{1/n}}(\pi_{1,\partial M}) \), the isomorphism \( \varphi^*_{1/n} \) on cohomology is given by

\[
 \varphi^*_{1/n} = \varphi^* \otimes \text{Id}_{v^{\rho_{1/n}}(\pi_{1,\partial M})}.
\]

For \( n = \infty \), we have

\[
 i^*_l \circ \varphi^*_0 = i^*_l \quad \text{and} \quad i^*_m \circ \varphi^*_0 = -i^*_m.
\]

**Proof.** If \( n \geq 4 \) then \( \rho_{1/n}(m) \) is an elliptic element and \( \rho_{1/n}(l) \) is a pure hyperbolic translation. This can be seen for example by using the trace identity

\[
 \text{tr} \rho(l) = \text{tr}^4 \rho(m) - 5 \text{tr}^2 \rho(m) + 2,
\]
which holds for every irreducible representation \( \rho: \Gamma \to SL(2, \mathbb{C}) \) (see for example [25, p. 113]). Hence up to conjugation we may assume that

\[
\rho_{1/n}(m) = \begin{pmatrix}
\cos(2\pi/n) & -\sin(2\pi/n) & 0 & 0 \\
\sin(2\pi/n) & \cos(2\pi/n) & 0 & 0 \\
0 & 0 & 1 & 0 \\
0 & 0 & 0 & 1
\end{pmatrix}
\]

and

\[
\rho_{1/n}(I) = \begin{pmatrix}
1 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 \\
0 & 0 & \cosh(\lambda_n) & \sinh(\lambda_n) \\
0 & 0 & \sinh(\lambda_n) & \cosh(\lambda_n)
\end{pmatrix}.
\]

With this normalization we obtain

\[
v^{\rho_{1/n}(\pi_1 \partial M)} = \langle \begin{pmatrix}
1 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 \\
0 & 0 & -1 & 0 \\
0 & 0 & 0 & 1
\end{pmatrix} \rangle
\]

and

\[
A_{1/n} = \begin{pmatrix}
1 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 \\
0 & 0 & \cosh(\lambda_n) & \sinh(\lambda_n) \\
0 & 0 & \sinh(\lambda_n) & \cosh(\lambda_n)
\end{pmatrix}.
\]

where \( R_\alpha \) is a rotation of angle \( \alpha \in \mathbb{R} \) and \( T_\eta \) is a hyperbolic translation of length \( \eta \in \mathbb{R} \). The actual values of \( \alpha \) and \( \eta \) are not needed since the above form of \( A_{1/n} \) already implies that it acts trivially on \( v^{\rho_{1/n}(\pi_1 \partial M)} \) i.e.

\[
\text{Ad}_{A_{1/n}} |_{v^{\rho_{1/n}(\pi_1 \partial M)}} = \text{Id}_{v^{\rho_{1/n}(\pi_1 \partial M)}},
\]

and the first assertion of the lemma follows.

In order to prove the second assertion recall that

\[
\rho_0(m) = \rho_0(x) = \exp \left( \begin{pmatrix}
0 & 0 & 0 & 0 \\
0 & 0 & -1 & 0 \\
0 & 1 & 0 & 0 \\
0 & 1 & 0 & 0
\end{pmatrix} \right) \quad \text{and} \quad \rho_0(l) = \begin{pmatrix}
0 & 0 & -2\sqrt{3} & 2\sqrt{3} \\
0 & 0 & 0 & 0 \\
2\sqrt{3} & 0 & 0 & 0 \\
2\sqrt{3} & 0 & 0 & 0
\end{pmatrix}.
\]

Hence \( A_0 = M \begin{pmatrix}
1 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 \\
0 & 0 & 1 & 0 \\
0 & 0 & 0 & 1
\end{pmatrix} \) for some \( M \) in the parabolic group that fixes \( v_+ = \text{Fix}(\langle \rho_0(m), \rho_0(l) \rangle) \), and that maps \( v_- \), the point fixed by the parabolic group containing \( \rho_0(y) \), to \( \rho_0(yx^{-1}) \cdot v_- \), because \( \varphi_0(y) = yx^{-1}y^{-1}xy^{-1} \).

With respect to our normalization we have

\[
v_+ = \begin{pmatrix}
0 \\
0 \\
1 \\
1
\end{pmatrix}, \quad v_- = \begin{pmatrix}
0 \\
0 \\
-1 \\
1
\end{pmatrix} \quad \text{and} \quad \rho_0(yx^{-1}) \cdot v_- = \begin{pmatrix}
\sqrt{3} \\
-1 \\
0 \\
2
\end{pmatrix}.
\]
Hence
\[
M = \exp \left( \begin{array}{ccc}
0 & 0 & -\sqrt{3}/2 \\
0 & 0 & 1/2 \\
\sqrt{3}/2 & -1/2 & 0
\end{array} \right) \quad \text{and} \quad A_0 = \begin{pmatrix}
1 & 0 & -\sqrt{3}/2 \\
0 & -1 & 1/2 \\
\sqrt{3}/2 & 1/2 & -1/2
\end{pmatrix}.
\]

Let us consider the two cocycles \( z_m, z_l : \pi_1(\partial M) \to \mathfrak{v}_{\rho_0} \) which were constructed in the proof of Lemma 5.4: \( z_m : \pi_1(\partial M) \to \mathfrak{v}_{\rho_0} \) given by \( z_m(l) = 0 \) and \( z_m(m) = a_l \) where
\[
a_l = \begin{pmatrix}
-1 \\
3 \\
-1 \\
-1
\end{pmatrix} \in \mathfrak{v},
\]
and \( z_l : \pi_1(\partial M) \to \mathfrak{v}_{\rho_0} \) given by \( z_l(l) = a_m \) and \( z_l(m) = 0 \) where
\[
a_m = \begin{pmatrix}
3 \\
-1 \\
-1 \\
-1
\end{pmatrix} \in \mathfrak{v}.
\]

These cocycles satisfy:
\[
i_m^*(z_m) \neq 0, \quad i_l^*(z_l) = 0,
\]
\[
i_m^*(z_l) = 0, \quad i_l^*(z_m) \neq 0.
\]

Moreover we have
\[
\varphi_0^*z_m(m) = \Ad_{A_0^{-1}} z_m(m^{-1})
\]
\[
= - \Ad_{A_0^{-1}} \Ad_{\rho_0(m)}^{-1} a_l
\]
\[
= - \begin{pmatrix}
1 & 0 & 0 & 0 \\
0 & 3 & 2 & -2 \\
0 & 2 & 0 & -9 \\
0 & 2 & 9 & -2
\end{pmatrix}
\]
and
\[
\varphi_0^*z_m(l) = \Ad_{A_0^{-1}} z_m(l) = 0.
\]

Since
\[
\langle i_m^*\varphi_0^*z_m, a_m \rangle = B(a_m, \varphi_0^*z_m(m)) = 32 = -B(a_m, a_l)
\]

35
it follows that $i_m^* \phi_0^* z_m \sim -i_m^* z_m$ (see the argument at the end of the proof of Lemma 5.4). On the other hand we have:

$$\varphi_0^* z_l(m) = 0 \text{ and } \varphi_0^* z_l(l) = \text{Ad}_{A_0^{-1}}(a_m) = \begin{pmatrix} 3 & 0 & -2\sqrt{3} & 2\sqrt{3} \\ 0 & -1 & 0 & 0 \\ -2\sqrt{3} & 0 & 2 & -3 \\ -2\sqrt{3} & 0 & 3 & -4 \end{pmatrix}.$$ 

Since $B(a_l, \varphi_0^* z_l(l)) = -32 = B(a_l, a_m)$ it follows that $i_l^* \varphi_0^* z_l \sim i_l^* z_l$. 

\[ \Box \]

### 8.3 Corollary

For sufficiently large $n \in \mathbb{N}$ the composition

$$H^1(M, v_{p_1/n}) \hookrightarrow H^1(\partial M, v_{p_1/n}) \to H^1(m, v_{p_1/n})$$

is the zero map.

**Proof.** The longitude $l$ is a flexing slope (see Remark 8.1). Thus by Lemma 8.2 the map $\varphi_0^* : H^1(M, v_{p_1}) \to H^1(M, v_{p_0})$ is the identity.

Next notice that for $n$ sufficiently large, we have an inclusion

$$H^1(M, v_{p_1/n}) \hookrightarrow H^1(\partial M, v_{p_1/n}).$$

The eigenvalues of $\varphi_1/n : H^1(\partial M, v_{p_1/n}) \to H^1(\partial M, v_{p_1/n})$ are $\pm 1$ since the restriction of $\varphi_1/n$ to the subgroup generated by $m$ and $l$ is an involution. Moreover, $\varphi_1/n$ preserves $H^1(M, v_{p_1/n}) \hookrightarrow H^1(\partial M, v_{p_1/n})$ and hence the induced map $\varphi_1/n$ on $H^1(M, v_{p_1/n})$ is $\pm \text{Id}$ and by continuity this restriction is the identity.

On the other hand we have $\varphi_1/n(m) = m^{-1}$, hence by Lemma 8.2 and Lemma 8.4 $\varphi_1/n$ induces $-\text{Id}$ on the image of $H^1(\partial M, v_{p_1/n}) \to H^1(m, v_{p_1/n})$. 

\[ \Box \]

### 8.4 Lemma

There is a natural isomorphism $H^*(\mathcal{O}_n, v_{p_1/n}) \cong H^*(\Gamma_1/n, v_{p_1/n}).$

**Proof.** The orbifold $\mathcal{O}_n$ has a finite cyclic covering $\widetilde{\mathcal{O}_n} \to \mathcal{O}_n$ where $\widetilde{\mathcal{O}_n}$ is a manifold. The compact, hyperbolic manifold $\widetilde{\mathcal{O}_n}$ is aspherical, hence there is a canonical isomorphism

$$H^*(\pi_1(\widetilde{\mathcal{O}_n}), v_{p_1/n}) \cong H^*(\widetilde{\mathcal{O}_n}, v_{p_1/n}).$$

Then the lemma follows since $H^*(\pi_1(\mathcal{O}_n), v_{p_1/n})$ and $H^*(\mathcal{O}_n, v_{p_1/n})$ are the invariant subspaces of the map $t^*$ induced by the covering transformation $t : \widetilde{\mathcal{O}_n} \to \mathcal{O}_n$, i.e.

$$H^*(\pi_1(\mathcal{O}_n), v_{p_1/n}) = H^*(\pi_1(\widetilde{\mathcal{O}_n}), v_{p_1/n})^t \text{ and } H^*(\mathcal{O}_n, v_{p_1/n}) = H^*(\widetilde{\mathcal{O}_n}, v_{p_1/n})^t.$$ 

\[ \Box \]
8.5 Proposition For sufficiently large $n \in \mathbb{N}$ we have

1. $H^1(\Gamma_{1/n}, \mathfrak{sl}(4)_{\rho_{1/n}}) \cong H^1(\Gamma_{1/n}, \nu_{\rho_{1/n}}) \cong \mathbb{R}$ is one-dimensional and $\varphi_{1/n}$ acts trivially on it.

2. $H^2(\Gamma_{1/n}, \mathfrak{sl}(4)_{\rho_{1/n}}) \cong H^2(\Gamma_{1/n}, \nu_{\rho_{1/n}}) \cong \mathbb{R}$ is one-dimensional and $\varphi_{1/n}^*$ acts by multiplication by $-1$ on it.

Proof. We start with the decomposition

$$H^*(\Gamma_{1/n}, \mathfrak{sl}(4)_{\rho_{1/n}}) = H^*(\Gamma_{1/n}, \mathfrak{so}(3,1)_{\rho_{1/n}}) \oplus H^*(\Gamma_{1/n}, \nu_{\rho_{1/n}}).$$

The group $H^1(\Gamma_{1/n}, \mathfrak{so}(3,1)_{\rho_{1/n}}) = 0$ vanishes by Weil’s infinitesimal rigidity and hence

$$H^2(\Gamma_{1/n}, \mathfrak{so}(3,1)_{\rho_{1/n}}) = 0$$

by Poincaré duality and Lemma 8.3. Thus

$$H^i(\Gamma_{1/n}, \mathfrak{sl}(4)_{\rho_{1/n}}) = H^i(\Gamma_{1/n}, \nu_{\rho_{1/n}}) \text{ for } i = 1, 2.$$ 

In order to compute $H^i(\Gamma_{1/n}, \nu_{\rho_{1/n}}) \cong H^i(\mathcal{O}_n, \nu_{\rho_{1/n}})$ we shall apply the Mayer-Vietoris sequence to the decomposition $\mathcal{O}_n = M \cup N_n$ where $N_n = \mathcal{N}(\text{Sing}(\mathcal{O}_n))$ is a regular neighborhood of the singular locus such that $M \cap N_n = \partial M$. Since

$$H^0(\mathcal{O}_n, \nu_{\rho_{1/n}}) \cong H^0(M, \nu_{\rho_{1/n}}) \cong \nu_{\rho_{1/n}}^{\pi_1(M)} = 0$$

and

$$H^0(\partial M, \nu_{\rho_{1/n}}) \cong \nu_{\rho_{1/n}}^{\pi_1(\partial M)} = \nu_{\rho_{1/n}}^{\pi_1(N_n)} \cong H^0(N_n, \nu_{\rho_{1/n}}),$$

we obtain the following exact sequence

$$H^1(\mathcal{O}_n, \nu_{\rho_{1/n}}) \to H^1(M, \nu_{\rho_{1/n}}) \oplus H^1(N_n, \nu_{\rho_{1/n}}) \to H^1(\partial M, \nu_{\rho_{1/n}}) \to H^2(\mathcal{O}_n, \nu_{\rho_{1/n}}).$$

Notice that the last arrow is surjective, as $\dim H^2(\partial M, \nu_{\rho_{1/n}}) = \dim H^2(M, \nu_{\rho_{1/n}}) = 1$. By Corollary 8.3 both groups $H^1(M, \nu_{\rho_{1/n}})$ and $H^1(N_n, \nu_{\rho_{1/n}})$ have the same image in $H^1(\partial M, \nu_{\rho_{1/n}})$ which is exactly the kernel of the map $H^1(\partial M, \nu_{\rho_{1/n}}) \to H^1(m, \nu_{\rho_{1/n}})$. Notice also that $\dim H^1(\partial M, \nu_{\rho_{1/n}}) = 2$ and

$$\dim H^1(N_n, \nu_{\rho_{1/n}}) = \dim H^0(N_n, \nu_{\rho_{1/n}}) = \dim \nu_{\rho_{1/n}}^{\pi_1(N_n)} = 1.$$ 

Therefore we get $\dim H^1(\mathcal{O}_n, \nu_{\rho_{1/n}}) = 1$. Moreover, the map $\varphi_{1/n}^*$ acts trivially on $H^1(\mathcal{O}_n, \nu_{\rho_{1/n}})$ since by the proof of Corollary 8.3 it acts trivially on $H^1(M, \nu_{\rho_{1/n}})$, and $H^1(\mathcal{O}_n, \nu_{\rho_{1/n}})$ injects into $H^1(M, \nu_{\rho_{1/n}})$. 

37
On the other hand we have
\[ H^1(\partial M, v_{\rho_{1/n}}) \cong H^1(\partial M, \mathbb{R}) \otimes v^{\rho_{1/n}}(\pi_1\partial M), \]
\( \varphi(m) = m^{-1} \) and \( \varphi(l) = l \). Hence the eigenvalues of \( \varphi^*_{1/n} : H^1(\partial M, v_{\rho_{1/n}}) \to H^1(\partial M, v_{\rho_{1/n}}) \) are \( \pm 1 \). The eigenspace corresponding to the eigenvalue \( +1 \) is the image of \( H^1(M, v_{\rho_{1/n}}) \) (and \( H^1(N_n, v_{\rho_{1/n}}) \)). Hence \( \varphi^*_{1/n} \) acts as \( -\text{Id} \) on \( H^2(O_n, v_{\rho_{1/n}}) \).

**Proof of Proposition** Let \( C \) be a finitely presented group and let \( \rho : \Gamma \to GL(m, \mathbb{R}) \) be a representation. A formal deformation of \( \rho \) is a representation \( \rho_t : \Gamma \to GL(m, \mathbb{R}[\![t]\!] ) \) such that \( \rho_0 = \rho \). Here \( \mathbb{R}[\![t]\!] \) denotes the ring of formal power series and \( \rho_0 : \Gamma \to \mathbb{C} \) is the evaluation of \( \rho_t \) at \( t = 0 \).

Every formal deformation \( \rho_t \) of \( \rho \) can be written in the form
\[ \rho_t(\gamma) = (I_m + tu_1(\gamma) + t^2u_2(\gamma) + \cdots )\rho(\gamma) \]
where \( I_m \) denotes the identity matrix and \( u_i : \Gamma \to \mathfrak{gl}(m) \) are maps i.e. elements of \( C^1(\Gamma, \mathfrak{gl}(m)_\rho) \). An easy calculation gives that \( u_1 \in Z^1(\Gamma, \mathfrak{gl}(m)_\rho) \) is a cocycle (Weil’s theorem). More generally we have the following:

**8.6 Lemma** Let \( \rho : \Gamma \to GL(m) \) be a homomorphism. Then \( \rho_t : \Gamma \to GL(m, \mathbb{R}[\![t]\!] ) \) given by
\[ \rho_t(\gamma) = (I_m + tu_1(\gamma) + t^2u_2(\gamma) + t^3u_3(\gamma) + \cdots )\rho(\gamma) \]
is a homomorphism if and only if for all \( k \in \mathbb{Z} \), \( k \geq 1 \), we have
\[ \delta u_k + \sum_{i=1}^{k-1} u_i \cup u_{k-i} = 0 . \]

The proof of this lemma is an easy calculation, by induction on \( k \). Here the cup product \( \cup \) is the composition of the usual cup product \( \cup \) with the matrix multiplication
\[ H^1(\Gamma, \mathfrak{gl}(m)_\rho) \otimes H^1(\Gamma, \mathfrak{gl}(m)_\rho) \xrightarrow{\cup} H^2(\Gamma, \mathfrak{gl}(m)_\rho \otimes \mathfrak{gl}(m)_\rho) \xrightarrow{\cup} H^2(\Gamma, \mathfrak{gl}(m)_\rho) \]
i.e. given to cochains \( c_1, c_2 \in C^1(\Gamma, \mathfrak{gl}(m)_\rho) \) the cup product \( c_1 \cup c_2 \in C^1(\Gamma, \mathfrak{gl}(m)_\rho) \) is given by
\[ c_1 \cup c_2(\gamma_1, \gamma_2) = c_1(\gamma_1) \text{Ad}_{\rho(\gamma_1)}(c_2(\gamma_2)). \]

The sequel the representation \( \rho \) is going to be always \( \rho_{1/n} \), hence we omit it from notation. Note that the \( \Gamma_{1/n} \)-module \( \mathfrak{gl}(4) \) decomposes as a direct sum
\[ \mathfrak{gl}(4) = \mathbb{R} \oplus \mathfrak{sl}(4) \]
38
where $R \cong R \cdot J_n$ is the trivial module, it is the center of $\mathfrak{gl}(4)$. Moreover $H^i(\Gamma_{1/n}, R) = 0$ for $i = 1, 2$ since $H_1(M_n, \mathbb{Z})$ is finite (no root of unity is a zero of the Alexander polynomial of the figure eight-knot). Hence

$$H^i(\Gamma_{1/n}, \mathfrak{gl}(4)) = H^i(\Gamma_{1/n}, v)$$

for $i = 1, 2$.

First we claim that the cup product

$$H^1(\Gamma_{1/n}, \mathfrak{gl}(4)) \otimes H^1(\Gamma_{1/n}, \mathfrak{gl}(4)) \xrightarrow{\cup} H^2(\Gamma_{1/n}, \mathfrak{gl}(4))$$

vanishes. This is because $H^i(\Gamma_{1/n}, \mathfrak{gl}(4)) = H^i(\Gamma_{1/n}, v)$, $i = 1, 2$, and $\varphi^*_{1/n}$ acts as multiplication with $(-1)^{i+1}$ on $H^i(\Gamma_{1/n}, v)$ by Proposition 8.5.

Hence

$$-(v \cup v) = \varphi^*_{1/n}(v \cup v) = \varphi^*_{1/n}(v) \cup \varphi^*_{1/n}(v) = (v \cup v).$$

Therefore the first obstruction to integrability of a vector $v \in H^1(\Gamma_{1/n}, \mathfrak{gl}(4))$ which is this cup product $v \cup v$ vanishes. The next obstruction is a Massey product: if $u_1 \in Z^1(\Gamma_{1/n}, \mathfrak{sl}(4))$ is a cocycle representing $v$, then $u_1 \cup u_1 + \delta u_2 = 0$, for some 1-cochain $u_2$, and the Massey product $\langle v \rangle^3$ is the cohomology class of $u_1 \cup u_2 + u_2 \cup u_1$. In general this is not unique, because $u_2$ can be replaced $u_2 + z$ for any cocycle $z$, which means that two possible values for $\langle v \rangle^3$ differ by an element in $v \cup H^1(\Gamma_{1/n}, \mathfrak{gl}(4)) + H^1(\Gamma_{1/n}, \mathfrak{gl}(4)) \cup v$. Since the cup product vanishes, $\langle v \rangle^3$ is unique. Using the naturality of the constructions and by Proposition 8.5 (1), we have:

$$\varphi^*_{1/n}(\langle v \rangle^3) = \langle \varphi^*_{1/n}(v) \rangle^3 = \langle v \rangle^3$$

Moreover, by Proposition 8.5 (2) and uniqueness of the Massey product,

$$\varphi^*_{1/n}(\langle v \rangle^3) = -\langle v \rangle^3,$$

which implies that $\langle v \rangle^3 = 0$. In a similar way, one can define all Massey products of higher order and the same argument shows that they are zero (see [21]). This implies that all obstructions to integrability vanish, and we apply Artin’s theorem [2], to conclude that formal integrability implies actual integrability of $v$.

\[\square\]

### 8.3 The Whitehead link

A similar computation as for the figure eight knot tells us that the Whitehead link $L = K_1 \sqcup K_2$ is infinitesimally projectively rigid. Let $\Gamma = \pi_1(M)$ denote the fundamental group of the Whitehead link exterior $M$. We will work with the presentation:

$$\Gamma = \langle x, y \mid xy^{-1}x^{-1}yx^{-1}y^{-1}xyx^{-1}yxy^{-1}xyx^{-1}y^{-1} \rangle$$
where \( x \) is a meridian for \( K_1 \) and \( y \) is a meridian for \( K_2 \). The holonomy representation \( \rho: \Gamma \to SL_2(\mathbb{C}) \) is given by

\[
\begin{align*}
x & \mapsto \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} \\
y & \mapsto \begin{pmatrix} 1 & 0 \\ -1 - i & 1 \end{pmatrix}
\end{align*}
\]

(see [29] for details). A computation analogous to the one of the previous subsection shows that \( \dim H^1(M; v_{Ad\rho}) = 2 \).

Once we know the dimension of the deformation space, we have a geometric tool to understand the deformations: let \( S \) denote the thrice punctured sphere illustrated in Figure 1. By symmetry of the component \( s \) of the link, there are two of them. The surface \( S \) intersects one boundary torus in a longitude \( l_x = yx^{-1}y^{-1}xy^{-1}x^{-1}yx \), and the other one in two meridians \( y \) and \( z = x^{-1}y^{-1} xy^{-1}yx \), with opposite orientation. The restriction of the holonomy onto \( \pi_1(S) \) is conjugate to a representation into \( SL_2(\mathbb{R}) \). Hence \( S \) a totally geodesic thrice puncture sphere in the link complement.

**8.7 Lemma** Let \( \partial_1M \) denote the boundary component of \( K_1 \). Every slope on \( \partial_1M \) different from the longitude \( l_x \) is a flexing slope.

**Proof.** We consider the bending along \( S \). If we restrict this bending to \( \partial_1M \), it is itself a bending along the longitude \( l_x \), and it happens to be precisely the deformation constructed in the proof of Lemma 5.4. Thus, except for the longitude itself, this deformation is nontrivial when restricted
to any slope of the torus, because the cusp shape of the Whitehead link lies in the Gaussian integers \( \mathbb{Z}[i] \), thus the angle of any slope with the longitude \( l_x \) can never be \( \pi/3 \), and we can apply Lemma 5.4.

Proof of Proposition 1.9. Lemma 8.7 and Proposition 7.2 imply that for almost all \( n \) the \((n,1)\)-Dehn fillings are infinitesimally projectively rigid. According to [1] those fillings are precisely the punctured torus bundles with tunnel number one.

Twists knots are obtained by \((1,n)\)-Dehn fillings, but we cannot apply Proposition 7.2 because the longitude is not a flexing slope. However, the path \((p,q) = (1,s)\) for \( s \in \mathbb{R} \) and \( s \geq 1 \) is contained in the whole deformation space (cf. [1]). Hence, since the coefficients \((1,1)\) correspond to the figure eight knot exterior, with an argument similar to Theorem 1.5, the \((1,n)\)-Dehn fillings are infinitesimally rigid for all but finitely many \( n \). □
