Abstract

In this paper, we present the construction of a geometric object, called a generalized flag geometry \((X^+, X^-)\), corresponding to a \((2k + 1)\)-graded Lie algebra \(g = g_k \oplus \cdots \oplus g_{-k}\). We prove that \((X^+, X^-)\) can be realized inside the space of inner filtrations of \(g\) and we use this realization to construct “algebraic bundles” on \(X^+\) and \(X^-\) and some sections of these bundles. Thanks to these constructions, we can give a realization of \(g\) as a Lie algebra of polynomial maps on the positive part of \(g\), \(n_1^+ := g_1 \oplus \cdots \oplus g_k\), and a trivialization in \(n_1^+\) of the action of the group of automorphisms of \(g\) by “birational” maps.

AMS classification: 17A15, 17B66.

Key words: Jordan pair, Kantor pair, graded and filtered Lie algebra, Bergman operator, torsor.

1 Introduction

It is well-known (see [Loo75]) that 3-graded Lie algebras \(g = g_1 \oplus g_0 \oplus g_{-1}\) give rise to Jordan pairs \((V^+, V^-) = (g_1, g_{-1})\), where the trilinear Jordan-structure is given by \(T^\pm(x, y, z) = [[x, y], z]\), and that, conversely, the 3-graded Lie algebra can be reconstructed from a (linear) Jordan pair by the Tits-Kantor-Koecher construction. The Jordan pair can then be interpreted as the “infinitesimal structure” corresponding to a global geometry \((X^+, X^-)\), called generalized projective geometry in [Ber02b]. Thus 3-graded Lie algebras correspond to generalized projective geometries, and in [BN04], an explicit and purely algebraic construction of a “universal model” of these geometries in terms of 3-filtrations of the Lie algebra has been given.

The topic of the present work is to extend these results to \(Z\)-graded Lie algebras of the type

\[ g = g_k \oplus g_{k-1} \oplus \cdots \oplus g_{-k}, \]

which we call \((2k + 1)-\text{graded}\). Especially the 5-graded case has already attracted much attention, mainly because every simple complex Lie algebra (of dimension bigger than 3) admits a 5-grading having the special feature that the spaces \(g_{\pm 2}\) are one-dimensional, and then the pair \(g_{\pm 1}\) corresponds to Freudenthal-Kantor pairs (see [Kan72], [Kam89] or [AF99]); also, this particular situation is related to geometric topics such as symplectic geometry (see [Rub94]) and quaternionic symmetric spaces (the so-called Wolf-spaces, cf. [Ber02a]). The typical situation that we consider here is in a certain sense opposite to this very particular case: we do not assume \(g\) to be simple, nor finite-dimensional, nor even defined over a field but rather over a commutative base ring \(K\) (the only assumption we will need is that certain integers are invertible in \(K\)). In this general situation, it is much less clear what object replaces the Jordan pair from the 3-graded case; it is known, by work of I. Kantor, that the pair \((g_1, g_{-1})\) is a generalized Jordan pair (a sort of non-commutative version of a Jordan pair, see [Kan70] and [Kan72]),
but this pair seems to be “too small” if one is looking for an object corresponding to the geometry of the whole graded algebra. Indeed, the problem of finding the good analog of the Jordan pair in the higher graded case remains open, but we hope that a good understanding of the geometry \((X^+, X^-)\) we construct will be a step towards the solution of this problem.

The geometry associated to a \((2k + 1)\)-graded Lie algebra \(\mathfrak{g}\), which we call a \textit{generalized flag geometry}, is constructed as follows: we consider the space \(\mathcal{F}\) of all \((2k + 1)\)-filtrations of \(\mathfrak{g}\), and we define a natural notion of \textit{transversality of filtrations} (Definition 2.3). We prove that two filtrations \(e\) and \(f\) are transversal (denoted by \(e \cap f\)) if and only if they come from a grading (then \(e\) is the “ascending” and \(f\) the “descending” filtration, see Part 1 of Theorem 2.1). Our key result (Part 3 of Theorem 2.1) says that the set \(f^\top\) of all filtrations \(e\) that are transversal to a given filtration \(f\) carries a natural \textit{torsor structure} (where we use the term “torsor” in the same way as in [BK09]): there is a natural, simply transitive group action on \(f^\top\), hence, after choice of an arbitrary origin, \(f^\top\) becomes a group. In the case of 3-filtrations, this group is a vector group (underlying an affine space, see [BN04]), whereas for \(k > 1\), it is no longer abelian but rather unipotent, with “Lie algebra” the positive (or negative, according to choice) part \(n_1^\top := \mathfrak{g}_1 \oplus \ldots \oplus \mathfrak{g}_k\), and instead of an affine space, we have a dilatation action making this group a \textit{Carnot group} (see, e.g., [Bul07]). These facts make the higher graded situation geometrically much more complicated, as we shall explain now.

We fix a \((2k + 1)\)-grading of \(\mathfrak{g}\) as “base point”, which corresponds to two transversal filtrations \(o^+\) and \(o^-\), and we consider the “connected components” \(X^\pm\) of \(\mathcal{F}\) containing \(o^\pm\) (Section 3). For any \(f \in X^\pm\), the torsor \(f^\top\) belongs to \(X^\top\) (Theorem 3.1); we call this structure a \textit{linear pair geometry}. Our aim is then to describe geometric structures of \(X^\pm\) with respect to the “charts” \(f^\top\): first of all, we give an algebraic description of the “intersection of chart domains” \(f^\top \cap e^\top\) in terms of certain cocycles called \textit{denominators} and \textit{co-denominators} (Definition 3.5 and Corollary 3.1). These are related to a generalization of the well-known \textit{Bergman operator} from Jordan-theory; more intrinsically, we define, in a purely algebraic way, certain vector bundles over \(X^\pm\), and then relate these operators to invariant sections of such bundles, called the \textit{canonical kernel} (Definition 4.3 and Theorem 4.2). Next, we describe the action of the \textit{projective elementary group} (which is the natural symmetry group in this context, acting transitively on \(X^\pm\), see Section 3.1) with respect to the “charts” \(f^\top\). This description is explicit and algebraic (in case of finite dimension over a field, it is indeed a birational group action), but the formulas are considerably more complicated than in the 3-graded case (Proposition 4.2). They generalize the classical description of the projective group on projective space, given in an affine picture by fractional-linear maps (see Example 4.4.1). In subsequent work, we will use this description for proving that, under suitable topological assumptions on \(\mathbb{K}\) and on \(\mathfrak{g}\), the geometries \(X^\pm\) are indeed smooth manifolds and that the algebraically defined bundles are smooth bundles with smooth section given by the canonical kernel. These results will give new and interesting examples of smooth infinite dimensional geometries, associated to infinite dimensional Lie algebras.

As an intermediate step to the description of the group action, we give a realization of its “Lie algebra” (which is essentially \(\mathfrak{g}\)) with respect to the “chart” \(f^\top\). It is given by vector fields (sections of the algebraically defined tangent bundle) which turn out to be \textit{polynomial} (Section 4.3), but again this description is much more complicated than in the 3-graded case; in this case, the polynomials are quadratic, and the algebraic structure of this polynomial Lie algebra is directly related to the Jordan pair structure (see [BN04] and [Upm85]). In the higher graded case, the missing analog of the Jordan pair makes it much more difficult to understand the polynomials arising from the polynomial realization of \(\mathfrak{g}\). It seems likely that a conceptual understanding of this situation should use the notion of \textit{generalized contact structure}, proposed in [CDMKR05]: indeed, in loc. cit. it is shown that (under suitable assumptions on a simple Lie algebra over \(\mathbb{R}\)), the projective elementary group can be indeed characterized as the group preserving the generalized contact structure, which thus appears to be a key feature of this situation. We intend to come back to this question in subsequent work.

This results are part of the author’s thesis [Che10] and some of them have been announced in a note [Che09].
Notation: In this paper, $\mathbb{K}$ is a commutative ring with $\mathbb{N} \subset \mathbb{K}^\times$. Let $k \in \mathbb{N}$.

## 2 Filtered and graded Lie algebras

In this part, we define the two notions of filtrations and gradings for a $\mathbb{K}$-module and for a Lie algebra and focus on links between them. Let $V$ be a $\mathbb{K}$-module and $\mathfrak{g}$ a Lie algebra over $\mathbb{K}$.

### 2.1 Filtrations and gradings of $\mathbb{K}$-modules

**Definition 2.1.** A $\mathbb{K}$-filtration of the module $V$ is a flag of subspaces of $V$:

$$\mathfrak{f} = (0 \subset f_k \subset f_{k-1} \subset \cdots \subset f_1 = V).$$

Two filtrations $e$ and $\mathfrak{f}$ are called transversal, and we write $e \pitchfork \mathfrak{f}$, if

$$V = e_n \oplus f_{k-n+2}, \text{ for } 2 \leq n \leq k-1.$$

**Definition 2.2.** A $\mathbb{K}$-grading of $V$ is a family $(V_1, \ldots, V_k)$ of subspaces of $V$, such that

$$V = V_1 \oplus \cdots \oplus V_k.$$

Each grading $(V_1, \ldots, V_n)$ defines two transversal filtrations $\mathfrak{f}^+$ and $\mathfrak{f}^-$, defined, for $1 \leq n \leq k$, by:

$$\mathfrak{f}^+_n := V_k \oplus \cdots \oplus V_n,$n$$

$$\mathfrak{f}^-_{k-n+1} := V_{n+1} \oplus \cdots \oplus V_1.$$

Conversely, by [BL08], two transversal filtrations come from a grading of $V$:

**Proposition 2.1.** Two filtrations $e$ and $\mathfrak{f}$ of $V$ are transversal if and only if they come from a grading of $V$, i.e. if and only if there exists a grading $V = V_1 \oplus \cdots \oplus V_k$ such that $e = \mathfrak{f}^+$ and $\mathfrak{f} = \mathfrak{f}^-$. Moreover, if $e$ and $\mathfrak{f}$ are transversal, the corresponding grading is defined by $V_n := e_n \cap \mathfrak{f}_{k-n+1}$.

**Proof.** See Proposition 3.3 of [BL08].

### 2.2 Filtrations of Lie algebras

**Definition 2.3.** A $(2k+1)$-filtration of a Lie algebra $\mathfrak{g}$ is a flag of subspaces of $\mathfrak{g}$:

$$n = (0 = n_{k+1} \subset n_k \subset \cdots \subset n_{-k+1} \subset n_{-k} = \mathfrak{g}),$$

such that $[n_m, n_n] \subset n_{m+n}$.

Such a flag will be denoted by $n = (n_0 \subset \cdots \subset n_{-k+1})$.

Two $(2k+1)$-filtrations $m$ and $n$ are called transversal, and we write $m \pitchfork n$, if they are transversal flags in the sense of the preceding subsection, i.e. $\mathfrak{g} = m_n \oplus n_{-n+1}$, for all $-k+1 \leq n \leq k$.

We say that a filtration is complemented if it admits a transversal filtration, and the set of such complemented filtrations will be denoted by $\tilde{\mathcal{F}}$.

Given a filtration $n$, we define the Lie algebra

$$u(n) := \{ X \in \text{Der}(\mathfrak{g}) | Xn_n \subset n_{n+1}, \text{ for all } -k+1 \leq n \leq k \}.$$

The elements $X$ of $u(n)$ are nilpotent. Hence, since integers are assumed to be invertible in $\mathbb{K}$, we can consider the unipotent “Lie group” corresponding to $u(n)$:

$$U(n) := e^{u(n)} := \{ e^X | X \in u(n) \}, \text{ where } e^X = \sum_{n=0}^{2k} \frac{X^n}{n!} \in \text{Aut}(\mathfrak{g}).$$
2.3 Short $\mathbb{Z}$-gradings of Lie algebras

**Definition 2.4.** A $(2k + 1)$-**grading** of $\mathfrak{g}$ is a family $(\mathfrak{g}_{-k}, \ldots, \mathfrak{g}_k)$ of submodules of $\mathfrak{g}$ such that

$$\mathfrak{g} = \bigoplus_{n=-k}^{k} \mathfrak{g}_n, \text{ with } [\mathfrak{g}_m, \mathfrak{g}_n] \subseteq \mathfrak{g}_{m+n} \text{ and } \mathfrak{g}_n = 0 \text{ if } |n| > k.$$ 

If $\mathfrak{g} = \mathfrak{g}_k \oplus \cdots \oplus \mathfrak{g}_{-k}$ is $(2k+1)$-graded, the map $D : \mathfrak{g} \to \mathfrak{g}$ defined, for $x \in \mathfrak{g}_n$, by $Dx = nx$, is a derivation, called the *characteristic derivation* of the grading, which satisfies

$$(D - k \text{Id}) \ldots (D - \text{Id}) D (D + \text{Id}) \ldots (D + k \text{Id}) = 0.$$ 

(1)

Conversely, any derivation $D$ satisfying (1) is diagonalizable and the eigenspace decomposition is a $(2k + 1)$-grading of $\mathfrak{g}$. Hence, we can identify the space of $(2k+1)$-gradings of $\mathfrak{g}$ with the set

$$\tilde{\mathcal{G}} := \{D \in \text{Der}(\mathfrak{g}) | (D - k \text{Id}) \ldots (D - \text{Id}) D (D + \text{Id}) \ldots (D + k \text{Id}) = 0 \}.$$ 

If an element $D \in \tilde{\mathcal{G}}$ can be written $D = \text{ad} (E)$, $E \in \mathfrak{g}$, then the grading is called *inner*, and the element $E$ is called an *Euler operator* of the grading. We denote by

$$\mathcal{G} := \{ \text{ad} (E) | E \in \mathfrak{g}, \text{ad} (E) \in \tilde{\mathcal{G}} \},$$

the set of inner $(2k + 1)$-gradings of $\mathfrak{g}$.

2.4 Transversality and gradings

If $\mathfrak{g} = \mathfrak{g}_k \oplus \cdots \oplus \mathfrak{g}_{-k}$ is a $(2k+1)$-graded Lie algebra, two filtrations are defined by

$$n^+(D) := (\mathfrak{g}_k \subseteq \mathfrak{g}_k \oplus \mathfrak{g}_{k-1} \subseteq \cdots \subseteq \mathfrak{g}_k \oplus \cdots \oplus \mathfrak{g}_{-k+1}),$$

and

$$n^-(D) := (\mathfrak{g}_{-k} \subseteq \mathfrak{g}_{-k} \oplus \mathfrak{g}_{-k+1} \subseteq \cdots \subseteq \mathfrak{g}_{-k} \oplus \cdots \oplus \mathfrak{g}_{k-1}).$$

The filtration $n^+(D)$ is called the *plus-filtration* and $n^-(D)$ the *minus-filtration* of the grading. If $D = \text{ad} (E)$ is inner, the filtration $n^+(\text{ad} (E))$ is also called *inner* and we denote by $\mathcal{F}$ the set of all inner filtrations. Observe that, by construction, the filtrations $n^+(D)$ and $n^-(D)$ defined by a grading of $\mathfrak{g}$ are transversal. Conversely, the following holds:

**Theorem 2.1.** (1) Let $m$ and $n$ be two filtrations of $\mathfrak{g}$. Then $m$ and $n$ are transversal if and only if they come from a grading of $\mathfrak{g}$, defined by $\mathfrak{g}_n = m_n \cap n_{-n}$, i.e. there exists $D \in \tilde{\mathcal{G}}$ such that $m = n^+(D)$ and $n = n^-(D)$. In other words, $\tilde{\mathcal{F}} = \{ n^+(D), D \in \tilde{\mathcal{G}} \}$.

(2) Let $n = n^+(D) \in \tilde{\mathcal{F}}$. Then $U(n) \cdot D = D + u(n)$, where $U(n)$ acts on $\text{Der}(\mathfrak{g})$ by $g \cdot D := g \circ D \circ g^{-1}$.

(3) Let $n \in \tilde{\mathcal{F}}$. Then the group $U(n)$ acts simply transitively on $n^+ := \{ m \in \tilde{\mathcal{F}}, m \cap n \}$.

**Proof.** (1) We have already remarked that $n^+(D) \cap n^-(D)$. Conversely, let us assume that $m \cap n$. According to Proposition 2.1, the flags $m$ and $n$ come from a grading of the module $\mathfrak{g}$, defined by $\mathfrak{g}_n = m_n \cap n_{-n}$. This is actually a grading in the sense of Lie algebras, i.e. $[\mathfrak{g}_m, \mathfrak{g}_n] \subseteq \mathfrak{g}_{m+n}$. Indeed,

$$[\mathfrak{g}_m, \mathfrak{g}_n] \subset [m_m, m_n] \cap [n_{-m}, n_{-n}] \subset m_{m+n} \cap n_{-(m+n)} = \mathfrak{g}_{m+n}.$$ 

Hence, $m$ and $n$ come from a $(2k + 1)$-grading of $\mathfrak{g}$.

(2) Since $e^X = \text{Id} + \sum_{n=1}^{2k} X^n$, for $X \in u(n)$, the inclusion $U(n) \cdot D \subset D + u(n)$ holds.

In order to prove the converse, let us fix $X \in u(n)$ and show, by induction, that for $2 \leq n \leq 2k + 1$, there exist $Y_n, R_n \in u(n)$ such that

$$e^{Y_n} De^{-Y_n} = D + X + R_n \text{ and } R_n (n_i) \subset n_{i+n}, \text{ for all } -k + 1 \leq i \leq k.$$
This implies that, for \( n = 2k + 1 \), \( R_n(\mathfrak{g}) \subset n_{k+1} = 0 \), hence \( e^{Y_{2k+1}} D e^{-Y_{2k+1}} = D + X \), and the claim follows:

\[
U(n) \cdot D \supset D + u(n).
\]

Now, we start the inductive proof: let \( n = 2 \) and define \( Y_2 := -X \in u(n) \). Then

\[
e^{Y_2} D e^{-Y_2} = \left( 1 - X + \sum_{j=2}^{2k+1} \frac{(-1)^j X^j}{j!} \right) D \left( 1 + X + \sum_{j=2}^{2k+1} \frac{X^j}{j!} \right)
= D + [D, X] + R_2, \text{ with } R_2(n_i) \subset n_{i+2}.
\]

Let us consider \( g = \bigoplus g_n \), the \((2k+1)\)-grading of \( g \) defined by \( D \). On the one hand, for \( x \in g_i \), \( XDx = iXx \in n_{i+1} \), while, on the other hand, \( DXx = (i + 1)Xx + Z_{i+2} \), where \( Z_{i+2} \in n_{i+2} \). Thus, \([D, X] x = Xx + Z_{i+2} \), and

\[
e^{Y_2} D e^{-Y_2} = D + X + R_2, \text{ with } R_2(n_i) \subset n_{i+2}.
\]

Moreover, \( R_2 = e^{Y_2} D e^{-Y_2} - D - X \in u(n) \), and our claim is proved for \( n = 2 \).

Now, let \( n \in \mathbb{N} \) and assume that there exist \( Y_n, R_n \in u(n) \) such that

\[
e^{Y_n} \cdot D = D + X + R_n \text{ and } R_n(n_i) \subset n_{i+n}.
\]

We define \( Y_{n+1} \) by

\[
Y_{n+1} := Y_n + \frac{1}{n} R_n \in u(n).
\]

It follows that

\[
e^{Y_{n+1}} = e^{Y_n + \frac{1}{n} R_n} = \sum_{j=0}^{2k+1} \left( Y_n + \frac{1}{n} R_n \right)^j \frac{1}{j!}
= 1 + Y_n + \frac{1}{n} R_n + \sum_{j=2}^{2k+1} \left( Y_n + \frac{1}{n} R_n \right)^j \frac{1}{j!}
= e^{Y_n} + \frac{1}{n} R_n + R_{n+1}, \text{ with } R_{n+1}(n_i) \subset n_{i+n+1}.
\]

Similarly, \( e^{-Y_{n+1}} = e^{-Y_n} - \frac{1}{n} R_n + R_{n+1}, \text{ with } R_{n+1}(n_i) \subset n_{i+n+1} \).

For \( x \in g_i \), \( D e^{-Y_{n+1}} x = D e^{-Y_n} x - \frac{i + n}{n} R_n x + Z_{i+n+1}^{(1)} \), with \( Z_{i+n+1}^{(1)} \in n_{i+n+1} \). Hence

\[
e^{Y_{n+1}} D e^{Y_{n+1}} x = e^{Y_n} D e^{-Y_n} x - \frac{i + n}{n} R_n D e^{-Y_n} x + Z_{i+n+1}^{(2)} \text{, with } Z_{i+n+1}^{(2)} \in n_{i+n+1}
= D x + X x + R_n x - \frac{i + n}{n} R_n x + \frac{i + n}{n} R_n x + Z_{i+n+1}^{(3)} \text{, with } Z_{i+n+1}^{(3)} \in n_{i+n+1}
= D x + X x + Z_{i+n+1}^{(3)}
\]

thus \( e^{Y_{n+1}} \cdot D = D + X + R_{n+1} \), with \( R_{n+1}(n_i) \subset n_{i+n+1} \). As explained above, the claim follows.

(3) First, we prove the transitivity of the action. Let \( \mathfrak{n} = \mathfrak{n}^+(D) \) be a filtration and \( \mathfrak{m} \in \mathfrak{n}^+ \) a filtration transversal to \( \mathfrak{n} \). According to Part 1), there exists a grading \( D' \) such that \( \mathfrak{m} = \mathfrak{n}^-(D') \) and \( \mathfrak{n} = \mathfrak{n}^+(D') \). We claim that \( D - D' \in u(n) \). Indeed, if we denote by

\[
g = \bigoplus_{n=-k}^k g_n \text{ and } g' = \bigoplus_{n=-k}^k g'_n
\]

the gradings defined by \( D \) and \( D' \), as \( \mathfrak{n}^+(D) = \mathfrak{n} = \mathfrak{n}^+(D') \), we have \( g_k \oplus \cdots \oplus g_n = n_n = g'_k \oplus \cdots \oplus g'_n \). It follows that, for \( x \in n_n \), \( Dx = nx + Z_{n+1} \), with \( Z_{n+1} \in n_{n+1} \), and similarly, \( D'x = nx + Z'_{n+1} \), with \( Z'_{n+1} \in n_{n+1} \). Hence, \( (D - D') x = Z_{n+1} - Z'_{n+1} \in n_{n+1} \). In other words, \( D - D' \in u(n) \), i.e.

\[
D' \in D + u(n).
\]
It follows, from Part 2), that there exists \( X \in u(n) \) such that \( D' = e^X \cdot D \). Then

\[
\mathfrak{m} = n^-(D') = n^-(e^X \cdot D) = e^X \cdot n^-(D),
\]

proving that the group \( U(n) \) acts transitively on \( n^\top \).

Moreover, if \( e^X \cdot n^-(D) = n^-(D) \) with \( X \in u(n) \), necessarily \( e^X = \text{Id} \), and hence the action is simply transitive.

According to Theorem 2.1 and using the terminology of [BL08], \( \left( \mathcal{F}, \mathcal{F}^+, \mathcal{F}^- \right) \) is a linear pair geometry, i.e. for any filtration \( n \in \mathcal{F} \), there is a transversal filtration \( m \), and the set \( n^\top \) carries a structure of \( K \)-module by declaring the map \( u(n) \rightarrow n^\top \), \( X \mapsto e^X \cdot m \) to be a linear isomorphism.

**Corollary 2.1.** If \( n = n^+(\text{ad}(E)) \in \mathcal{F} \) is an inner filtration of \( \mathfrak{g} \), then we have

\[
u(n) = \text{ad}(n_1) \quad \text{and} \quad U(n) = e^{\text{ad}(n_1)}.
\]

Moreover, two transversal inner filtrations come from an inner grading of \( \mathfrak{g} \).

**Proof.** For the first statement, we fix \( X \in u(n) \) and prove by induction that, for all \( 2 \leq n \leq 2k+1 \), there are an element \( Y^n \in n_1 \) and a derivation \( R_n \in u(n) \) such that \( \text{ad}(Y^n) = X + R_n \) and \( R_n(n_i) \subset n_{n+i} \), for all \(-k+1 \leq i \leq k \).

The second statement is proved in [Che09].

\[
\square
\]

## 3 Generalized flag geometry

In this section, we shall define a geometric object, called a generalized flag geometry, associated with an inner \((2k+1)\)-grading of \( \mathfrak{g} \), and realize this geometry by inner filtrations of \( \mathfrak{g} \).

**Definition 3.1.** We call a base point of \( \mathcal{F} \times \mathcal{F} \) a couple \((m, n)\) of transversal inner filtrations. In this instance, according to Corollary 2.1, \( m \) and \( n \) come from an inner grading of \( \mathfrak{g} \). In other words, \( m = n^+(\text{ad}(E)) \) and \( n = n^-(\text{ad}(E)) \). That is why, the base points of \( \mathcal{F} \times \mathcal{F} \) will be denoted by \((n^+, n^-)\).

### 3.1 Projective elementary group

Let \((n^+, n^-)\) be a base point of \( \mathcal{F} \times \mathcal{F} \), i.e. we fix an inner grading of \( \mathfrak{g} \). Then \( n^+ = n^+(\text{ad}(E)) \) and \( n^- = n^-(\text{ad}(E)) \). We consider the following subgroups of \( \text{Aut}(\mathfrak{g}) \):

\[
U^+ := U(n^+) = e^{\text{ad}(n_1^+)} \quad \text{and} \quad U^- := U(n^-) = e^{\text{ad}(n_1^-)}.
\]

**Definition 3.2.** The group generated by \( U^+ \) and \( U^- \), \( G := PE(\mathfrak{g}, E) := \langle U^+, U^- \rangle < \text{Aut}(\mathfrak{g}) \), is called the projective elementary group of \((\mathfrak{g}, E)\).

We also consider the following subgroups of \( G \): the subgroup of \( G \) preserving the grading,

\[
H := \{ g \in G, g \circ \text{ad}(E) = \text{ad}(E) \circ g \},
\]

and

\[
P^+ := HU^+ \quad \text{and} \quad P^- := HU^-.
\]

Since the elements of \( H \) commute with the characteristic derivation, they normalize \( U^\pm \). Thus, \( P^+ \) and \( P^- \) are indeed subgroups of \( G \).
3.2 Generalized flag geometry

With notation as above, we define homogeneous spaces:

\[ M := G/H, \quad X^+ := G/P^- \text{ and } X^- := G/P^+. \]

The base point \((P^+, P^-)\) of \(X^- \times X^+\) is denoted by \((o^-, o^+)\).

**Theorem 3.1.** With the above notation, we have:

1. The orbits of \(D = \text{ad}(E)\), respectively of \(n^\pm\), under the action of \(G\) are isomorphic to \(M\), respectively to \(X^\pm\), i.e.

   \[ H = \{ g \in G, \ g.(n^+, n^-) = (n^+, n^-) \} \quad \text{and} \quad P^\pm = \{ g \in G, \ g.n^\pm = n^\pm \}. \]

   Moreover, \(P^+ \cap P^- = H\), \(P^\pm \cap U^\mp = \{ 1 \}\), and

   \[ P^\pm = \{ g \in G, \ gDg^{-1} - D \in \text{ad}(n^\pm) \}. \]

2. Let \(x \in X^+\) and \(y \in X^-\). If we identify \(X^\pm\) with the corresponding orbits in \(F\), then \(x\) and \(y\) are transversal if and only if there exists \(g \in G\) such that \(x = g.o^+\) and \(y = g.o^-\).

3. For any \(m \in X^-\), we have \(m^\top \subset X^+.\) In particular, \(n^+_1\) is identified with \((o^-)^\top\) via \(v \mapsto e^{\text{ad}(v)} o^+\) so that we may consider that the space \(n^+_1\) is embedded in \(X^+.\)

4. Let us consider the set \(\Omega^+: = \{ g \in G, \ g.o^+ \in n^+_1 \}.\) The map

   \[ n^+_1 \times H \times n^-_1 \to \Omega^+, \quad (v, h, w) \mapsto e^{\text{ad}(v)}he^{\text{ad}(w)} \]

   is a bijection.

**Proof.** (1) An element \(g \in G\) stabilizes \((n^+, n^-)\) if and only if it stabilizes the grading of \(g\), which means that \(g\) commutes with the derivation \(D\), i.e. \(g \in H\). Hence

\[ H = \{ g \in G, \ g.(n^+, n^-) = (n^+, n^-) \}. \]

Moreover, \(U^+\) and \(H\) stabilize \(n^+.\) This implies that \(P^+\) also stabilizes \(n^+.\) Conversely, if \(g \in G\) satisfies \(g.n^+ = n^+\), then \(g.n^-\) is transversal to \(g.n^+ = n^+.\) It follows that there exists \(v \in n^+_1\) such that \(g.n^- = e^{\text{ad}(v)}n^-\). Hence \(h := e^{-\text{ad}(v)}g\) stabilizes \(n^+\) and \(n^-,\) i.e. \(h \in H\). Therefore \(g = e^{\text{ad}(v)}h \in P^+.\) The same also holds for \(P^-\).

Thus \(P^+ \cap P^-\) is the stabilizer of \((n^+, n^-)\). It means that \(P^+ \cap P^- = H\).

Next, if \(g \in P^+ \cap U^-,\) then \(g = e^{\text{ad}(v)}\), with \(v \in n^-_1\). By Part 3) of Theorem 2.1, the map \(v \mapsto e^{\text{ad}(v)} n^+\) is injective. Hence, since \(g.n^+ = n^+, \ v = 0\) and \(g = 1\).

Finally, \(g.n^+ = n^+\) if and only if \(D\) and \(Dg^{-1}\) have the same plus-filtration, that is to say, from Section 2.4, if and only if \(Dg^{-1} - D \in \text{ad}(n^+_1) = u(n^+)\). Once again, the same applies for \(P^-\).

(2) Clearly, if \(g \in G\), then \(g.o^+ \equiv g.n^-\) and \(g.o^- \equiv g.n^+\) are transversal. Conversely, let \(x \in X^+\) and \(y \in X^-\) such that \(x\) and \(y\) are transversal. As \(y \in X^-\), there exists \(g \in G\) such that \(y = g.o^- \equiv g.n^+.\) Hence \(g^{-1}y \equiv n^+\), and \(g^{-1}x\) is transversal to \(n^+\). By Part 3) of Theorem 2.1, there exists \(v \in n^+_1\) such that \(g^{-1}x = e^{\text{ad}(v)}n^+.\) Thus \(x = ge^{\text{ad}(v)}o^+\), and \(y = g.o^- = ge^{\text{ad}(v)}o^-\), since \(e^{\text{ad}(n^+_1)}\) preserves \(n^+ \equiv o^-\).

(3) Let \(m = g.o^- \in X^-\). By Part 3) of Theorem 2.1, \(m^\top \subset X^+.\) In particular, \(o^- \in X^-\) and \((o^-)^\top = e^{\text{ad}(n^+_1)}o^+.\)
3.3. Corollary [Mey70] for the definition of We also define, for $i \leq n_1^+$, such that $e^{-ad(x)}g.o^+ = o^+$ and by Part 1), $p := e^{-ad(x)}g \in P^- = HU^-$. This implies that there is $w \in n_1^-$ such that $e^{-ad(x)}g = he^{-ad(w)}$. Thus $g = e^{ad(x)h}e^{ad(w)}$, and the map is surjective. Now, if $g = e^{ad(v_1)}h_1e^{ad(w_1)} = e^{ad(v_2)}h_2e^{ad(w_2)}$, then $e^{-ad(v_1)}e^{ad(v_2)}h_1 = h_2e^{-ad(w_2)}e^{ad(w_1)}$. But, by

Part 1), $P^+ \cap P^- = H$ so $v_1 = v_2$. Similarly, $w_1 = w_2$ and it implies that $h_1 = h_2$. Therefore, the map is injective too, hence is a bijection.

Actually, we have a $G$-equivariant imbedding $X^+ \times X^- \hookrightarrow \mathcal{F} \times \mathcal{F}$.

Definition 3.3. The data $(X^+, X^-, \mathcal{T})$ is called the generalized flag geometry (of $k$-graded type) of $(\mathfrak{g}, D)$.

Moreover, according to Theorem 3.1, $(X^+ \times X^-, \mathcal{T})$ is also a linear pair geometry. Indeed, for any $x \in X^\pm$, there exists $y \in X^\mp$ such that $x \mp y$, and $x^+ \mp x^-$ carries a structure of $\mathbb{K}$-module. In particular,

$$X^\pm = \bigcup_{y \in X^\mp} y^\mp. $$

In other words,

$$X^+ = \bigcup_{g \in G} g \left(n_1^+\right) \text{ and } X^- = \bigcup_{g \in G} g \left(n_1^-\right). $$

Definition 3.4. We shall say that

$$A := \{(g \left(n_1^+\right), \varphi_g) : g \in G\}, $$

where $\varphi_g : g \left(n_1^+\right) \subset X^+ \rightarrow n_1^+$, $g \cdot x \mapsto x$, is the natural atlas of $X^+$ and the maps $\varphi_g$ will be called the charts of the atlas $A$.

Now, let us define some operators which will be useful in the sequel.

Definition 3.5. For any $x \in n_1^+$ and $g \in \text{Aut}(\mathfrak{g})$, we define the denominators, resp. co-denominators, of $g$ by:

$$d_g(x)_i = \text{pr}_{n_1^+} \circ (e^{-ad(x)}g^{-1})\iota_{n_1^+} \in \text{End}(n_1^+), \text{ resp. } c_g(x)_i = \text{pr}_{n_1^-} \circ (ge^{ad(x)})\iota_{n_1^-} \in \text{End}(n_1^-), \text{ for } 1 \leq i \leq k,$$

where $\text{pr}_{n_1^\pm}$ is the projection of $\mathfrak{g}$ onto $n_1^\pm$ and $\iota_{n_1^\pm}$ is the imbedding of $n_1^\pm$ into $\mathfrak{g}$. Observe that, for any $1 \leq i \leq k$, the maps

$$d_g : n_1^+ \rightarrow \text{End}(n_1^+), \text{ } x \mapsto d_g(x)_i \text{ and } c_g : n_1^+ \rightarrow \text{End}(n_1^-), \text{ } x \mapsto c_g(x)_i,$$

are polynomial maps.

We also define, for $x \in n_1^+$, $w \in n_1^-$ and $1 \leq i \leq k$,

$$B^+(x, w)_i := d_{c_{ad(w)}(x)}(x)_i \text{ and } B^-(w, x)_i := c_{ad(w)}(x)_i.$$

These operators are called generalized Bergman operators.

Indeed, they can be considered as a generalization of Bergman operators of a Jordan pair [Loo75]. More precisely, if $\mathfrak{g} = TKK(V^+, V^-)$ is the Kantor-Koecher-Tits algebra of a Jordan pair $(V^+, V^-)$ (see [Mey70] for the definition of $TKK(V^+, V^-)$), then $k = 1$ and the operators $B^+(x, w) := d_{c_{ad(w)}(x)}(x)$ and $B^-(w, x) := c_{ad(w)}(x)$ are actually the Bergman operators of $(V^+, V^-)$ (see [BN04]).

Corollary 3.1. Let $x \in n_1^+$ and $g \in \text{Aut}(\mathfrak{g})$. Then the following statements are equivalent:

i) $g \cdot x \in n_1^+$, i.e. $n_1^+$ and $ge^{ad(x)}n_1^-$ are transversal.

ii) For all $i \in \{1, \ldots, k\}$, $d_g(x)_i$ and $c_g(x)_i$ are invertible.
Proof. By definition, \( n^+ \) and \( g \exp(\text{ad}(x)) \cdot n^- \) are transversal if and only if \( g = n^+_i \oplus g \exp(\text{ad}(x)) (n^-_{n-1}) \), for all \(-k+1 \leq n \leq k\). In other words, they are transversal if and only if, for all \( 1 \leq i \leq k \), \( g \exp(\text{ad}(x)) (g_{-k} \oplus \cdots \oplus g_{-i}) \) is a complement of \( g_k \oplus \cdots \oplus g_{-i+1} \) and \( g_{-k} \oplus \cdots g_{-i-1} \) is a complement of \( e^{-\text{ad}(x)} g^{-1} (g_k \oplus \cdots \oplus g_i) \), and this last statement is equivalent to ii).

In particular, with the notation of Theorem 3.1, we have

\[ \Omega^+ = \{ g \in G, \forall i \in \{1, \ldots, k\}, d_g(0), i, c_g(0)_i \text{ are invertible} \}. \]

4 Realization of \( g \) by polynomial vector fields

In this part, we define some algebraic objects that we call “bundles” on \( F \), even if we do not consider a topology. For example, we shall define the tangent and structural bundle of \( F \), as well as some sections of these bundles. Then, fixing a grading of \( g \), we shall consider the corresponding generalized flag geometry and construct a realization of \( g \) by polynomial fields on the positive part of the grading: \( n^+_i = \bigoplus_{n=1}^k g_n \).

Finally, we shall give a global version of this realization, i.e. we shall study the action of the projective elementary group on \( X^+ \) in the “chart” \( n^+_i \).

4.1 Bundles and vector fields

**Definition 4.1.** For any \((2k + 1)\)-filtration \( n = (n_k \subset n_{k-1} \subset \cdots \subset n_{-k+1}) \in F \), and any integer \( 1 \leq i \leq k \), we define the following \( K \)-modules:

\[ T_n^{(i)} F := g/n_{-i+1} \text{ and } T_n^{(i)} F := n_i. \]

To simplify the notations, instead of \( T_n^{(i)} F \), we write \( T_n F \) and call this module the tangent space of \( F \) at \( n \), using the terminology of [BN04]. Similarly, \( T_n^{(i)} F \) shall be denoted by \( T_n^i F \) and called the structural space of \( F \) at \( n \).

Observe that, if \( n = n^-(\text{ad}(E)) \) is the minus filtration defined by the Euler operator \( E \), then

\[ n_{-i+1} = g_{-k} \oplus \cdots \oplus g_{-k-1}, \quad n_i = g_{-i} \oplus \cdots \oplus g_{-i-1}, \text{ and } T_n^{(i)} F \cong g_k \oplus \cdots \oplus g_i \text{ and } T_n^{(i)} F = g_{-i-1} \oplus \cdots \oplus g_{-k}. \]

We also define the disjoint unions:

\[ T^{(i)} F := \bigcup_{n \in F} T_n^{(i)} F \text{ and } T^{(i)} F := \bigcup_{n \in F} T_n^{(i)} F, \]

so that the following projections may be defined:

\[ \pi^{(i)} : T^{(i)} F \rightarrow F, \quad Y \in T_n^{(i)} F \mapsto n \text{ and } \pi^{(i)} : T^{(i)} F \rightarrow F, \quad x \in T_n^{(i)} F \mapsto n. \]

We write \( T F := T^{(1)} F \) and \( T^i F := T^{(i)} F \) and call them the tangent bundle of \( F \) and the structural bundle of \( F \).

**Lemma 4.1.** If \( g \) is a semi-simple, finite dimensional Lie algebra over a field \( K \), then, for all \( n \in F \) and \( 1 \leq i \leq k \), \( T_n^{(i)} F \cong T_n^{(i)} F \).

**Proof.** Let \( n \in F \) be an inner filtration. Since \( n \) is inner, it comes from a grading \( g = g_k \oplus \cdots \oplus g_{-k} \).

If \( x \in g_k \) and \( y \in g_j \), then \( \text{ad}(x)(\text{ad}(y)(g_k)) \subset g_{i+j-1} \). But, \( g_i \cap g_{i+j+1} = \{0\} \) if \( i + j \neq 0 \). It implies that, if we choose a basis of each \( g_n \), we obtain a basis of \( g \) in which the matrix of \( \text{ad}(x) \text{ad}(y) \) has only zeros on the diagonal, so that the Killing form \( B(x, y) = \text{Tr}(\text{ad}(x) \text{ad}(y)) \) is zero. Hence, we can consider \( \tilde{B} : n_i \times g/n_{-i+1} \rightarrow K \), which is non-degenerate because \( g \) is semi-simple. Therefore, \( T^{(i)} F \cong T^{(i)} F \). \( \square \)
Thus, if \( g \) is a semi-simple, finite dimensional Lie algebra over a field, then the bundles \( T^{(i)}F \) are dual bundles of \( T^{(i)}F \), i.e. \( T^{(i)}F \cong (T^{(i)}F)^* \). In particular, the structural bundle \( T'F \) is the cotangent bundle \( T^*F \).

Since the group \( \text{Aut}(g) \) acts on \( G \) and \( F \), the following linear maps may be defined for any \( g \in \text{Aut}(g) \):

\[
T^{(i)}g : T^{(i)}n_i \rightarrow T^{(i)}g.n_i \quad \text{and} \quad T^{(i)}g : T^{(i)}F \rightarrow T^{(i)}g.F
\]

Then, defining the maps \( T^{(i)}g \) and \( T^{(i)}g \) as usual, it holds:

\[
T^{(i)}(g \circ h) = T^{(i)}g \circ T^{(i)}h \quad \text{and} \quad T^{(i)}(g \circ h) = T^{(i)}g \circ T^{(i)}h.
\]

Now, let us fix an inner grading of \( g \) and consider the associated generalized flag geometry. According to Theorem 3.1, \( X^\pm \subset F \), so that we may define the spaces \( T^{(i)}X^\pm, T^{(i)}X^\pm \), as well as the bundles \( T^{(i)}X^\pm \) and \( T^{(i)}X^\pm \). These bundles are, in an algebraic way, bundles associated to representations of \( P^- \) given by the denominators at 0, \( d_p(0)_i \), and the co-denominators at 0, \( c_p(0)_i \), introduced in Definition 3.5. More precisely, according to Corollary 3.1, for \( g = p \in P^- \) and \( x = 0, d_p(0)_i \), and \( c_p(0)_i \) are bijections and the following lemma holds.

**Lemma 4.2.** The maps \( \rho^+_i : P^- \rightarrow \text{Gl}(n^+_i), p \mapsto d_p(0)_i^{-1} \) and \( \rho^-_i : P^- \rightarrow \text{Gl}(n^-_i), p \mapsto c_p(0)_i \) are group homomorphisms.

**Proof.** Let \( p_1, p_2 \in P^- \). We have \( d_{p_1p_2}(0)_i = p_{p_1} \circ p_2^{-1} \circ p_{p_1}^{-1} \circ w_{n_i} \). Now, since \( p_2 \in P^- \), there is the identity:

\[
pr_{n_i} \circ p^{-1} = pr_{n_i} \circ p^{-1} \circ pr_{n_i}.
\]

We deduce that \( d_{p_1p_2}(0)_i = pr_{n_i} \circ p^{-1} \circ pr_{n_i} \circ p_{p_1}^{-1} \circ w_{n_i} = d_{p_1}(0)_id_{p_1}(0)_i \). Therefore,

\[
d_{p_1p_2}(0)_i^{-1} = d_{p_1}(0)_i^{-1}d_{p_2}(0)_i^{-1}.
\]

Moreover, it is obvious that \( c_{p_1p_2}(0)_i = c_{p_1}(0)_ic_{p_2}(0)_i \).

Now, let us focus our attention on \( \rho^+_i \). We consider the quotient

\[
G \times_{P^-} n_i^+ := G \times_{P^-} n_i^+ / \sim,
\]

where \( (g, x_i) \sim (gp, \rho^+_i(p)^{-1}x_i) \) for \( g \in G, x_i \in n_i^+ \) and \( p \in P^- \).

**Theorem 4.1.** For \( 1 \leq i \leq k \), \( T^{(i)}X^\pm \cong G \times_{P^-} n_i^+ \), i.e. there exists a \( G \)-equivariant bijection between \( T^{(i)}X^\pm \) and \( G \times_{P^-} n_i^+ \). We equally have \( T^{(i)}X^\pm \cong G \times_{P^-} n_i^+ \) and the same holds for \( X^- \), if we exchange \( P^- \) and \( P^+ \).

**Proof.** In order to prove the identity \( T^{(i)}X^\pm \cong G \times_{P^-} n_i^+ \), we consider the following map:

\[
\varphi^{(i)} : G \times_{P^-} n_i^+ \rightarrow T^{(i)}X^\pm, [g, x_i] \mapsto \left( T^{(i)}g \right)_{x_i} = g x_i \text{ mod } n_i^{-1}
\]

First, let us prove that \( \varphi^{(i)} \) is well-defined. If \( (gp, \rho^+_i(p)^{-1}x_i) \) is another representative of \( [g, x_i] \), then \( \left( T^{(i)}g \right)(p)^{-1}x_i = \left( T^{(i)}g \circ T^{(i)}p \right)_{d_p(0)_i}x_i \). But the map \( T^{(i)}g \circ T^{(i)}p \) is defined by

\[
T^{(i)}g \circ T^{(i)}p : T^{(i)}X^\pm \cong n_i^+ \rightarrow T^{(i)}X^\pm \cong n_i^+, \quad x_i \mapsto (pr_{n_i} \circ p)x_i.
\]

In other words, \( T^{(i)}p = d_p(0)_i^{-1} \). It implies that \( \left( T^{(i)}g \right)(p)^{-1}x_i = \left( T^{(i)}g \right)_{x_i} \), so that \( \varphi^{(i)} \) is well-defined.

Let \( m = g.o^+ \in X^+ \) and \( x \in T^{(i)}m^+ = g/m_{-1}^+ \). Since \( g^{-1}x \in T^{(i)}m^+ \cong n_i^+ \), it follows, from
Indeed, the following holds:

\[ \varphi^i([g, g^{-1}x]) = x \in T^{(i)}m, \text{ that } \varphi^i \text{ is surjective.} \]

Now, let \((g_1, g_2, x_1, x_2)\) such that \((T^{(i)}_{ao} g_1) x_1 = (T^{(i)}_{ao} g_2) x_2\).

First, we have \(g_1 o^+ = g_2 o^+, \text{ i.e. } g_1^{-1} g_2 o^+ = o^+ \) so \(g_1^{-1} g_2 = p \in P^-, \text{ i.e. } g_2 = g_1 p\). Hence \(T^{(i)}_{g_2 o} g_2 x_2 = (T^{(i)}_{g_1 o} g_1) d_p(0)_{x_2}^{-1} x_2\). Therefore \(x_1 - d_p(0)_{x_2}^{-1} x_2 \in \text{Ker}(T^{(i)}_{g_1 o} g_1)\). But, if \(x \in n^+\) is in the kernel of \(T^{(i)}_{g_1 o} g_1\), then \(g_1 x \in g(n_{-i+1})\), i.e. \(x \in n^+ \cap n_{-i+1} = \{0\}\). Thus, \(x_1 = d_p(0)_{x_2}^{-1} x_2\) and \((g_1, x_1) \sim (g_2, x_2)\), so that \(\varphi^i\) is injective. Finally, \(\varphi^i(g' [g, x_i]) = \varphi^i([g' g, x_i]) = (T^{(i)}_{g_2 o} g' o T^{(i)}_{g_1} g) x_1 = (T^{(i)}_{g_2 o} g') \cdot \varphi^i([g, x_i])\). Thus \(\varphi^i\) is \(G\)-equivariant, and \(T^{(i)}mX^+\) and \(G \times P^- n^+\) are isomorphic \(G\)-bundles.

The proofs are similar for the other statements.

Now, let us focus on sections on these bundles. In fact, sections of \(T^{(i)}F\) can be easily constructed. Indeed, the following holds:

**Definition 4.2.** For any \(Y \in g\) and \(1 \leq i \leq k\), we define the map

\[ \tilde{Y}^i : \mathcal{F} \to T^{(i)}F, \ n \mapsto Y^i_n, \]

where \(Y^i_n := Y \mod n_{-i+1} \in T^{(i)}n\).

In particular, for \(i = 1\), \(Y^1_n := Y^1_n\) is called the value of \(Y\) at \(n\), and the map \(\tilde{Y} : \mathcal{F} \to T\mathcal{F}, \ n \mapsto Y_n\) defines a vector field on \(\mathcal{F}\), called a projective vector field.

**Lemma 4.3.** The maps \(\tilde{Y}^i\) are sections of \(T^{(i)}F\).

**Proof.** By definition, \(\pi^i o \tilde{Y}^i(n) = \pi^i(Y \mod n_{-i+1}) = n\). Hence \(\pi^i o \tilde{Y}^i = \text{Id}_F\).

### 4.2 The canonical kernel

Let \((m, n) \in \mathcal{F}\). The spaces \(T_m \mathcal{F}\) and \(T'_m \mathcal{F}\) are filtered \(\mathbb{K}\)-modules:

\[ T^n_m \mathcal{F} = T^{(1)}_m \mathcal{F} \hookrightarrow T^{(2)}_m \mathcal{F} \hookrightarrow \cdots \hookrightarrow T^{(i)}_m \mathcal{F} \hookrightarrow \cdots \hookrightarrow T^{(k)}_m \mathcal{F} \quad \text{and} \]

\[ T'_m \mathcal{F} \hookleftarrow T^{(k-1)}_m \mathcal{F} \hookleftarrow \cdots \hookleftarrow T^{(k-i)}_m \mathcal{F} \hookleftarrow \cdots \hookleftarrow T'_m \mathcal{F}. \]

Observe that, for \(1 \leq i \leq k\), \(T^{(i)}_m \mathcal{F}\) is a subspace of \(g\) which defines sections of \(T^{(i)}F\), so that we may define the following \(\mathbb{K}\)-linear maps:

\[ K^{(i)}_{m,n} : T^{(i)}_m \mathcal{F} = m_i \to T^{(i)}_m \mathcal{F} = g/n_{-i+1}, \ Y \mapsto Y^{(i)}_n = Y \mod n_{-i+1}. \]

By definition, there is the following diagram:
4.3. According to Lemma 4.1, if 

\[ K \]

By definition, we define where the union is disjoint, and the projection

\[ \Pi \]

Thus \( \Pi \) is a bundle over

\[ F \] \times \[ F \]

\[ \mathcal{I}(F, F) \]

\[ \Pi(i) \] \circ \[ K(i) \] = \[ \text{id}_{F \times F} \]. Hence, \( K(i) \) is a section of the bundle

\[ \mathcal{I}(F, F) \]

Remark: According to Lemma 4.1, if \( g \) is a semi-simple, finite dimensional Lie algebra over a field, the space \( T_m^{(i)} F \) is isomorphic to \( \left( T_m^{(i)} F \right)^{\ast} \). Hence

\[ \text{Hom}^{(i)}(T^\prime F, T F) \cong \left( T^{(i)} F \right)^{\ast} \otimes T^{(i)} F = T^{(i)} F \otimes T^{(i)} F. \]

In other words, \( \text{Hom}^{(i)}(T^\prime F, T F) \) is a bundle over \( F \times F \) and if \( (m, n) \in F \) are two filtrations, the fiber over \( (m, n) \) is isomorphic to \( T_m^{(i)} F \otimes T_n^{(i)} F \).

In general case, the following holds:

**Theorem 4.2.** (1) The map \( K(i) \) is a \( G \)-equivariant section of \( \text{Hom}^{(i)}(T^\prime F, T F) \).

(2) Let \( (m, n) \in F \times F \) be two inner filtrations. Then, they are transversal if and only if, for all \( i = 1, \ldots, k \), the maps \( K_{m,n}^{(i)} \) and \( K_{n,m}^{(i)} \) are isomorphisms.
Proof. (1) The projective elementary group $G$ acts on $\text{Hom}^{(i)}(T'F,TF)$ as follows: if $g \in G$ and $\varphi \in \text{Hom}\left(T^{(i)}_mF,T^{(i)}_nF\right)$, then

$$g \cdot \varphi = T^{(i)}_ng \circ \varphi \circ \left(T^{(i)}_mg\right)^{-1} \in \text{Hom}\left(T^{(i)}_{g,m}F,T^{(i)}_{g,n}F\right).$$

Since we have already noted that $K^{(i)}$ is a section, we only have to prove that it is equivariant. Let $(m,n) \in F \times F$ and $g \in G$. The map $K^{(i)}_{g,n.g,m}$ is defined by:

$$K^{(i)}_{g,n.g,m}: T^{(i)}_gF \rightarrow T^{(i)}_nF, \ Y \in g(m) \mapsto Y \mod (n_{-i+1}).$$

Let $Y \in g(m)$. There exists $Z \in m$, such that $Y = gZ = \left(T^{(i)}_m g\right) Z$, and

$$K^{(i)}_{g,n.g,m}(gZ) = gZ \mod (n_{-i+1}) = \left(T^{(i)}_m g\right) \left(Z \mod (n_{-i+1})\right) = \left(T^{(i)}_n g\right) \left(K^{(i)}_{n.m}(Z)\right)$$

In other words,

$$K^{(i)}_{g,n.g,m} = T^{(i)}_n g \circ K^{(i)}_{n.m} \circ \left(T^{(i)}_m g\right)^{-1} = g \cdot K^{(i)}_{n,m},$$

i.e. $K^{(i)}$ is $G$-equivariant.

(2) The map $K^{(i)}_{n,m}$ is bijective if and only if $g = m \oplus n_{-i+1}$. Thus $m$ and $n$ are transversal if and only if, for all $1 \leq i \leq k$, the maps $K^{(i)}_{n,m}$ and $K^{(i)}_{m,n}$ are isomorphisms. \hfill \Box

From Theorem 3.1, there is an imbedding $X^+ \subset F$. Therefore, we can consider $\text{Hom}^{(i)}(T'X^+,TX^-)$ or $\text{Hom}^{(i)}(T'X^-,TX^+)$. These bundles are isomorphic to “associated bundles” (like $T^{(i)}X^\pm$ in Theorem 4.1). Indeed, the following holds:

**Theorem 4.3.** For all $i = 1, \ldots, k$, we have

$$\text{Hom}^{(i)}(T'X^+,TX^-) \cong (G \times G) \times_{(p_-,p_+)} \text{End}(n^-_i)$$

and

$$\text{Hom}^{(i)}(T'X^-,TX^+) \cong (G \times G) \times_{(p_+,p_-)} \text{End}(n^+_i),$$

where $(G \times G) \times_{(p_-,p_+)} \text{End}(n^-_i) := (G \times G) \times \text{End}(n^-_i)/\sim$ with $(g,g',\varphi) \sim (gp,g'p,\varphi), p \in (0)_{i-1}\varphi p_{-i}$ and $(G \times G) \times_{(p_+,p_-)} \text{End}(n^+_i) := (G \times G) \times \text{End}(n^+_i)/\sim$ with $(g,g',\varphi) \sim (gp,g'p,dp_{p+},p_{i-1}\varphi p_{-i-1}).$

**Proof.** The proof is similar to the one of Theorem 4.1. \hfill \Box

Now we can consider restrictions of canonical kernel $K^{(i)}$ over $X^+ \times X^-$ and regard it as a section of $\text{Hom}^{(i)}(T'X^\pm,TX^\mp)$. Moreover, if $x \in n^+_1 \subset X^+$ and $y \in n^-_1 \subset X^-$, the maps $K^{(i)}_{x,y}$ are given by

$$K^{(i)}_{x,y} \cdot T^{(i)}_{y.o}X^- \rightarrow T^{(i)}_{x.o}X^+, \ e^{ad(y)}y \mapsto pr_{n^+_1}\left(e^{-ad(x)}e^{ad(y)}Y\right).$$

In other words, $K^{(i)}_{x,y} = B^+(x,-y)_1$, i.e. $K^{(i)}_{x,y}$ is a generalized Bergman operator.

### 4.3 Realization of $g$ by polynomial fields

Now, let us fix an inner $(2k+1)$-grading of $g$ and consider the general flag geometry associated with $(g,D)$. In the previous part, we proved that $T^{(i)}X^+$ is isomorphic to $G \times_{p_-} n^+_i$. It allows us to identify $T^{(i)}X^+$ and $G \times_{p_-} n^+_i$. In addition, the maps $Y^{(i)}$ define sections of $T^{(i)}X^+$. But, we know that the sections of $G \times_{p_-} n^+_i$ are identified with the induced representation of $G$, so that they correspond to the functions $f : G \rightarrow n^+_i$ such that, for all $p \in P^+$, $f(gp) = dp(0),f(g)$. Indeed, let us consider such a function $f$ and define

$$s_f : X^+ \rightarrow T^{(i)}X^+, g_{o^+} \mapsto \left(T^{(i)}_{g_o^+}g\right) f(g).$$
Then $s_f$ is a section of $T^{(i)}X^+$, and all sections arise in this way. Precisely, the function corresponding to $\tilde{Y}^{(i)}$ is

$$f^{(i)}_Y : G \to n_1^+, \; g \mapsto \text{pr}_{n_1^+}(g^{-1}Y).$$

In particular, if $g = e^{ad(x)}$, with $x \in n_1^+$, we identify the restriction of $\tilde{Y}^{(i)}$ on $n_1^+$ with

$$\tilde{Y}^{+(i)} = f_{Y|_{n_1^+}} : n_1^+ \to n_1^+, \; x \mapsto \text{pr}_{n_1^+}(e^{-ad(x)}Y).$$

We remark that $x \mapsto \tilde{Y}^{+(i)}(x)$ is a polynomial map of $x$. Thus, we obtain a map

$$g \mapsto Pol(n_1^+), \; Y \mapsto \tilde{Y}^{+(i)},$$

where $Pol(n_1^+)$ is the space of polynomial self-mappings of $n_1^+$. In particular for $i = 1$, we obtain a realization of $g$ by polynomial fields on $n_1^+$. For example, if $g$ is 3-graded, there is only one such map:

$$\tilde{Y}^+ = \tilde{Y}^{+(1)} : x \mapsto \text{pr}_{g_1}(e^{-ad(x)}Y) = \text{pr}_{g_1}(Y - [x, Y] + \frac{1}{2}[x, [x, Y]]),$$

and we recover formulas of [BN04].

If $g$ is 5-graded, there are two such maps:

$$\tilde{Y}^{+(2)} : x \in g_2 \mapsto \text{pr}_{g_2}(e^{-ad(x)}Y) = \text{pr}_{g_2}(Y - [x, Y] + \frac{1}{2}[x, [x, Y]]).$$

Hence, we obtain the formulas corresponding to the 3-grading $g_2 \oplus g_0 \oplus g_2$:

- if $Y \in g_2, \tilde{Y}^{+(2)}(x) = Y$,
- if $Y \in g_1, \tilde{Y}^{+(2)}(x) = 0$,
- if $Y \in g_0, \tilde{Y}^{+(2)}(x) = -[x, Y]$,
- if $Y \in g_{-1}, \tilde{Y}^{+(2)}(x) = 0$,
- if $Y \in g_{-2}, \tilde{Y}^{+(2)}(x) = \frac{1}{2}[x, [x, Y]]$.

Note that we also have $\tilde{Y}^{+(1)} : x = x_1 + x_2 \in g_1 \oplus g_2 \mapsto \text{pr}_{g_1 \oplus g_2}(e^{-ad(x)}Y)$, i.e.

$$\tilde{Y}^{+(1)}(x) = \text{pr}_{g_1 \oplus g_2}(Y - [x, Y] + \frac{1}{2}[x, [x, Y]] - \frac{1}{6}[x, [x, [x, Y]]] + \frac{1}{24}[x, [x, [x, [x, Y]]]]).$$

More precisely,

- if $Y \in g_2, \tilde{Y}^{+(1)}(x) = Y$,
- if $Y \in g_1, \tilde{Y}^{+(1)}(x) = Y - [x, Y]$,
- if $Y \in g_0, \tilde{Y}^{+(1)}(x) = -[x_1, Y] - [x_2, Y] + \frac{1}{2}[x_1, [x_1, Y]],$
- if $Y \in g_{-1}, \tilde{Y}^{+(1)}(x) = -[x_2, Y] + \frac{1}{2}[x_1, [x_1, Y]] + [x_1, [x_2, Y]] - \frac{1}{6}[x_1, [x_1, [x_1, Y]]],$
- if $Y \in g_{-2}, \tilde{Y}^{+(2)}(x) = [x_1, [x_2, Y]] - \frac{1}{6}[x_1, [x_1, [x_1, Y]]] + \frac{1}{2}[x_2, [x_2, Y]] - \frac{1}{2}[x_1, [x_1, [x_2, Y]]] + \frac{1}{24}[x_1, [x_1, [x_1, [x_1, Y]]]]$.

### 4.4 Description of the $G$-action in the chart $n_1^+$

#### 4.4.1 Example: action by homographies

First, let us consider the example of $g = g_{l_n}(C)$ with the 3-grading defined by:

$$g_1 = \left\{ \begin{pmatrix} 0 & B \\ 0 & 0 \end{pmatrix}, B \in \mathcal{M}_{p,n-p}(C) \right\}, \; g_0 = \left\{ \begin{pmatrix} A & 0 \\ 0 & D \end{pmatrix}, A \in \mathcal{M}_p(C), D \in \mathcal{M}_{n-p}(C) \right\},$$

and $g_{-1} = \left\{ \begin{pmatrix} 0 & 0 \\ C & 0 \end{pmatrix}, C \in \mathcal{M}_{n-p,p}(C) \right\}$.
In this case, $G = \text{GL}_n(\mathbb{C})$ and

$$X^- \cong \text{Gras}_p(\mathbb{C}^n) \text{ and } X^+ \cong \text{Gras}_{n-p}(\mathbb{C}^n),$$
i.e. $X^-$ is the set of $p$-dimensional subspaces of $\mathbb{C}^n$ and $X^+$ the one of $n - p$ dimensional subspaces. In addition, $\mathfrak{n}_1^+ \cong \mathcal{M}_{p,n-p}(\mathbb{C})$ and $\mathfrak{n}_1^+ \to X^+$ via $X \mapsto \left\{ \left( \begin{array}{c} v \\ Xv \end{array} \right), v \in \mathbb{C}^{n-p} \right\}$. In this chart, the action of the group $G = \text{GL}_n(\mathbb{C})$ is given by

$$\left( \begin{array}{cc} A & B \\ C & D \end{array} \right) \cdot \left( \begin{array}{c} v \\ Xv \end{array} \right) = \left( \begin{array}{c} v \\ (C + DX)(A + BX)^{-1}v \end{array} \right),$$

if $(A + BX)$ is invertible. This condition means that the point $x = \left( \begin{array}{c} v \\ Xv \end{array} \right) \in \text{Gras}_p(\mathbb{C}^n)$ is not sent to infinity by $g = \left( \begin{array}{cc} A & B \\ C & D \end{array} \right)$. In other words, the projective group acts, in the chart $\mathfrak{n}_1^+$, by homographies.

### 4.4.2 General case: action by “birational” maps

In the sequel, we shall focus our attention on the action of the projective elementary group $G$ in the chart $\mathfrak{n}_1^+$. More precisely, for $g \in \text{Aut}(\mathfrak{g})$ and $x \in \mathfrak{n}_1^+$ such that $g \cdot x \in \mathfrak{n}_1^+$, $g \cdot x$ has a “birational” expression. For example, if $g$ is 3-graded, by [BN04], it holds:

$$g \cdot x = d_g(x)^{-1}n_g(x), \text{ where } x \mapsto n_g(x) \text{ is a quadratic polynomial map.}$$

When the grading is longer, the following holds:

**Proposition 4.1.** Let $g \in \text{Aut}(\mathfrak{g})$, and $x \in \mathfrak{n}_1^+$ such that $g \cdot x \in \mathfrak{n}_1^+$. Then

$$\left( \tilde{g^{-1}}Y \right)^+(i) \left( x \right) = d_g(x)e^{\text{ad}(g \cdot x)}Y^+(i)(g \cdot x).$$

Moreover, if $x \in \mathfrak{n}_1^+$ and $g_1, g_2 \in \text{Aut}(\mathfrak{g})$ are such that $g_2 \cdot x \in \mathfrak{n}_1^+$ and $g_1g_2 \cdot x \in \mathfrak{n}_1^+$, then

$$d_{g_1g_2}(x) = d_{g_2}(x)e^{\text{ad}(g_2 \cdot x)}d_{g_1}(g_2 \cdot x) = d_{g_2}(x)d_{Id}(g_2 \cdot x)^{-1}d_{g_1}(g_2 \cdot x).$$

**Proof.** Let $x \in \mathfrak{n}_1^+$ and $g \in \text{Aut}(\mathfrak{g})$ such that $g \cdot x \in \mathfrak{n}_1^+$. By Part 4) of Theorem 3.1, there exists $p(g, x) \in P^-$ such that $ge^{\text{ad}(g \cdot x)} = e^{\text{ad}(g^{-1})}p(g, x)$. It follows that

$$p(g, x)^{-1} = e^{-\text{ad}(g \cdot x)}g^{-1}e^{\text{ad}(g \cdot x)},$$

which implies that

$$p(g, x)^{-1} := \text{pr}_{\mathfrak{n}_1^+} o p(g, x)^{-1} o \tau_{\mathfrak{n}_1^+} = d_g(x)e^{\text{ad}(g \cdot x)} o \tau_{\mathfrak{n}_1^+} = d_g(x)d_{Id}(g \cdot x)^{-1},$$

because $g \cdot x \in \mathfrak{n}_1^+$. Hence,

$$\left( \tilde{g^{-1}}Y \right)^+(i) \left( x \right) = \text{pr}_{\mathfrak{n}_1^+} \left( e^{-\text{ad}(g \cdot x)}g^{-1}Y \right) = \text{pr}_{\mathfrak{n}_1^+} \left( p(g, x)^{-1}e^{-\text{ad}(g \cdot x)}Y \right).$$

Moreover, since $p(g, x)^{-1} \in P^-$, we have

$$\text{pr}_{\mathfrak{n}_1^+} o p(g, x)^{-1} = p(g, x)^{-1} o \text{pr}_{\mathfrak{n}_1^+},$$

i.e. for $y \in \mathfrak{g}$, the components in $\mathfrak{n}_1^+$ of $p(g, x)^{-1}y$ depend only on components of $y$ in $\mathfrak{n}_1^+$. Thus

$$\left( \tilde{g^{-1}}Y \right)^+(i) \left( x \right) = d_g(x)e^{\text{ad}(g \cdot x)}\text{pr}_{\mathfrak{n}_1^+} \left( e^{-\text{ad}(g \cdot x)}Y \right) = d_g(x)e^{\text{ad}(g \cdot x)}Y^+(i)(g \cdot x).$$
In particular, for $Y = v \in \mathfrak{n}_1^+$, we have
\[
(g^{-1}v)^+((g^{-1}v)) = d_g(x_1)e^{\text{ad}(g \cdot x)} \text{pr}_{\mathfrak{n}_1^+} \left( e^{-\text{ad}(g \cdot x)}v \right) = d_g(x) v.
\]

Now, if $g_2 \cdot x \in \mathfrak{n}_1^+$ and $g_1 g_2 \cdot x \in \mathfrak{n}_1^+$, then
\[
d_{g_1 g_2}(x) v = (g_2^{-1}g_1^{-1}v)^+((g_2^{-1}g_1^{-1}v))(g_2 \cdot x) = d_{g_2}(x) e^{\text{ad}(g_2 \cdot x)} (g_1^{-1}v)^+((g_1^{-1}v))(g_2 \cdot x).
\]

Hence $d_{g_1 g_2}(x) = d_{g_2}(x) e^{\text{ad}(g_2 \cdot x)} d_{g_1}(g_2 \cdot x) v$.

Now, we can give a “rational” expression for the action of $G$ on $\mathfrak{n}_1^+ \subset X^+$.

**Definition 4.4.** Let $g \in \text{Aut}(\mathfrak{g})$ and $x \in \mathfrak{n}_1^+$. We define
\[
n_g(x) := \text{pr}_{\mathfrak{n}_1^+} \left( e^{-\text{ad}(g \cdot x)} g^{-1}E \right),
\]
where $E$ is the Euler operator of the grading of $\mathfrak{g}$. Observe that $n_g(x) = (g^{-1}E)^+(x)$ and the map $n_g : \mathfrak{n}_1^+ \rightarrow \mathfrak{n}_1^+$, $x \mapsto n_g(x)$, called the numerator of $g$, is polynomial.

**Proposition 4.2.** Let $g \in \text{Aut}(\mathfrak{g})$ and $x \in \mathfrak{n}_1^+$ such that $g \cdot x \in \mathfrak{n}_1^+$. Then
\[
E - e^{\text{ad}(g \cdot x)}E = d_g(x)^{-1} n_g(x).
\]
More precisely, there is a map $\psi : \mathfrak{n}_1^+ \rightarrow \mathfrak{n}_1^+$ such that
\[
[E, g \cdot x] = d_g(x)^{-1} n_g(x) + \psi(g \cdot x).
\]

**Proof.** By definition, $(g^{-1}E)^+(x) = n_g(x)$, and by Proposition 4.1,
\[
(g^{-1}E)^+(x) = d_g(x) e^{\text{ad}(g \cdot x)} \text{pr}_{\mathfrak{n}_1^+} \left( e^{-\text{ad}(g \cdot x)}E \right).
\]
In other words,
\[
d_g(x) e^{\text{ad}(g \cdot x)} \text{pr}_{\mathfrak{n}_1^+} \left( e^{-\text{ad}(g \cdot x)}E \right) = n_g(x),
\]
i.e. $e^{\text{ad}(g \cdot x)} \text{pr}_{\mathfrak{n}_1^+} \left( e^{-\text{ad}(g \cdot x)}E \right) = d_g(x)^{-1} n_g(x)$. Since $g \cdot x \in \mathfrak{n}_1^+$, $\text{pr}_{\mathfrak{n}_1^+} \left( e^{-\text{ad}(g \cdot x)}E \right) = e^{-\text{ad}(g \cdot x)}E - E$ which implies that
\[
e^{\text{ad}(g \cdot x)} \text{pr}_{\mathfrak{n}_1^+} \left( e^{-\text{ad}(g \cdot x)}E \right) = E - e^{\text{ad}(g \cdot x)}E.
\]
Hence
\[
E - e^{\text{ad}(g \cdot x)}E = d_g(x)^{-1} n_g(x).
\]

Now, let us fix $v \in \mathfrak{n}_1^+$ and write $v = \sum_{n=1}^k v_n$, with $v_n \in \mathfrak{g}_n$. Then
\[
E - e^{\text{ad}(v)}E = [E, v] + \frac{1}{2} [v, [E, v]] + \cdots + \sum_{n=1}^k n v_n + \psi_n(v_1, \ldots, v_{n-1}),
\]
where the map $\psi_n : \mathfrak{g}_1 \times \mathfrak{g}_2 \times \cdots \times \mathfrak{g}_{n-1} \rightarrow \mathfrak{g}_n$ is $(n-1)$-linear and is the part of the component of $E - e^{\text{ad}(v)}E$ in $\mathfrak{g}_n$ which only depends on $v_1, \ldots, v_{n-1}$. For example, we have $\psi_1, \psi_2 = 0$, $\psi_3(v_1, v_2) = \frac{1}{2}[v_1, v_2]$ and $\psi_4(v_1, v_2, v_3) = [v_1, v_3] + \frac{1}{3} [v_1, [v_1, v_2]]$. Therefore, if we write $v = \begin{pmatrix} v_k \\ \vdots \\ v_1 \end{pmatrix} \in \mathfrak{n}_1^+$, it holds:
\[
\begin{pmatrix}
(k(g \cdot x)_k + \psi_k ((g \cdot x)_1, \ldots, (g \cdot x)_{k-1}) \\
\vdots \\
3(g \cdot x)_3 + \frac{1}{2} [(g \cdot x)_1, (g \cdot x)_2] \\
2(g \cdot x)_2 \\
(g \cdot x)_1 
\end{pmatrix} = d_g(x)^{-1} n_g(x).
\]
It follows that \([E, g \cdot x] = d_g(x)^{-1} n_g(x) + \psi(g \cdot x)\), where \(\psi = \begin{pmatrix} \psi_k \\ \vdots \\ \psi_1 \end{pmatrix}\). More precisely, the map \(\text{ad}(E)\)
is bijective on \(n_1^+\), so that we may obtain \((g \cdot x)_1 = \text{pr}_{n_1}(d_g(x)^{-1} n_g(x))\), and for all \(2 \leq n \leq k\),

\[(g \cdot x)_n = \frac{1}{n} \left( d_g(x)^{-1} n_g(x) \right) - \frac{1}{n} \psi_n ((g \cdot x)_1, \ldots, (g \cdot x)_{n-1}).\]

Thus, if \(g\) is 3-graded, we recover the formula of [BN04], and in the general case of a \((2k + 1)\)-graded Lie algebra, we note that the projective elementary group acts in the chart \(n_1^+\) by birational maps.

As mentioned in the introduction, in this paper, we only consider purely algebraic issues. Using the differential calculus over a general topological ring defined in [BGN04], it is possible, under suitable assumptions on the subalgebras \(n_1^+\) and \(n_1^−\) and on the general Bergman operators, to construct a structure of smooth manifold on \(X^+\), resp. \(X^−\), modelled on \(n_1^+\), resp. \(n_1^−\). All algebraically defined bundles are then smooth bundles, the canonical kernel is a smooth section and the tangent bundle defined in Definition 4.1 coincides with the tangent bundle as a smooth manifold. Such a construction is made in [BN05] for a 3-graded Lie algebra and announced in [Che09] for a general \((2k + 1)\)-graded Lie algebra. Moreover, by definition \(T_{o^+}X^+ = g/n_0^\sim \cong n_1^+\), and there is a filtration of \(n_1^+\) given by

\[0 \subset g_1 \subset g_1^\oplus g_2 \subset \cdots \subset n_1^+\]

which is stable by the action of the group \(P^−\), so that we obtain a filtration of \(T_{o^+}X^+\). By the action of the projective elementary group, we also obtain a filtration of each \(T_xX^+\), for \(x \in X^+\). This distribution of filtrations is called a generalized contact structure [CDMKR05]. This structure seems to be a key feature to understand the generalized flag geometry better. That is why we intend to come back to this structure in subsequent work.
