Since January 2020 Elsevier has created a COVID-19 resource centre with free information in English and Mandarin on the novel coronavirus COVID-19. The COVID-19 resource centre is hosted on Elsevier Connect, the company's public news and information website.

Elsevier hereby grants permission to make all its COVID-19-related research that is available on the COVID-19 resource centre - including this research content - immediately available in PubMed Central and other publicly funded repositories, such as the WHO COVID database with rights for unrestricted research re-use and analyses in any form or by any means with acknowledgement of the original source. These permissions are granted for free by Elsevier for as long as the COVID-19 resource centre remains active.
Selenium supplementation in the prevention of coronavirus infections (COVID-19)

Selenium

A B S T R A C T

Selenium (Se) is a ubiquitous element akin to sulfur (S) existing in the Earth crust in various organic and inorganic forms. Selenium concentration varies greatly depending on the geographic area. Consequently, the content of selenium in food products is also variable. It is known that low Se is associated with increased incidence of cancer and heart diseases. Therefore, it is advisable to supplement diet with this element albeit in a proper form. Although blood increased concentrations of Se can be achieved with various pharmacological preparations, only one chemical form (sodium selenite) can offer a true protection. Sodium selenite, but not selenate, can oxidize thiol groups in the virus protein disulfide isomerase rendering it unable to penetrate the healthy cell membrane. In this way selenite inhibits the entrance of viruses into the healthy cells and abolishes their infectivity. Therefore, this simple chemical compound can potentially be used in the recent battle against coronavirus epidemic.

Background

Selenium (Se) is similar to sulfur (S) [1], but its concentration in Earth crust is much lower and its distribution is very uneven [2]. Sulfur, by contrast to selenium, is widely present in inorganic and organic compounds, particularly in proteins in the form of intra- or inter-molecular disulfides bridges, that determine their specific properties and functions. It is known, however, that such bridges are susceptible to the so-called disulfide exchange reaction and in this way alter their spatial configuration. A classic example is a limited disulfide reduction of human serum that results in the formation of a huge insoluble co-polymer composed of all its proteins [3], that is effectively inhibited by sodium selenite [4,5]. In nature Se exists mostly in two forms, namely as selenites with tetravalent (Se⁴⁺), and as selenates with hexavalent (Se⁶⁺) cations, respectively, from which all other selenium species are derived. Organic forms of selenium are found in plants, fruits, seeds and particularly in Brazilian nuts in the form of selenides e.g. as selenocysteine and selenomethionine. Human daily intake of Se varies greatly, from 50 to 600 µg/day depending on the geographical location of the soil on which food products are grown. In extreme cases, a very low content of Se in soil brings about pathologic consequences known as Keshan disease [6]. Grains are also important sources of dietary selenium. However, there are significant differences in the Se content in

grains cultivated in the North America (0.3–1.3 µg/g) and those grown e.g. in Sweden (0.007–0.22 µg/g). On the other hand, the selenium concentration in seafood is relatively high (0.1–3.9 µg/g). It was suggested decades ago that selenium may possess cancer-protecting effects in man, and that the selenium-deficient diet in the developed countries may contribute to increased incidence of malignant tumors [7] as well as to increased viral infections [8]. However, it should be strongly emphasized that only redox active selenite displays beneficial health effects.

It should be emphasized as well, that selenium can display toxicity to humans depending on the chemical form of this element [9]. One should also distinguish between selenium toxicity to normal cells versus neoplastic ones. In general, organic Se compounds are less toxic than inorganic, but the LD₅₀ doses vary greatly depending on the duration of exposure, the used model, and the blood levels achieved. More recently it was reported that intravenous administration of sodium selenite at the dose of 500 µg/day was completely non-toxic [10]. At the same time relatively high doses of selenite (up to 2000 µg/day) were reported to be well tolerated in patients with peritonitis [11]. The LD₅₀ dose for sodium selenite in rats was established to be 4100 µg/kg bodyweight, which is a hundred-fold greater than that generally accepted for humans. In humans, mild symptoms of toxicity in the form of reversible hair loss and fingernail brittleness start to occur at a dose of 1000 µg/
day one of year observation. Organic Se compounds are less toxic than inorganic, but the LD<sub>50</sub> doses vary greatly depending on the duration of exposure, the experimental model, and the blood concentrations achieved. More recently, Nuttal [9] indicated that selenium concentration in human serum ranges from 400 to 3000 µg/L, the levels > 1400 µg/L being non-toxic. It is generally believed, albeit not confirmed, that the toxic doses of selenium start from 600 µg/day. In view of such conflicting data on selenium toxicity, the author of this article had decided to ingest 10000 µg of sodium selenite in one dose. Subsequent tests revealed that neither bleeding time nor the blood coagulation rate performed within 0–24 h after the ingestion showed any abnormalities (unpublished data). These findings are very significant, since the human hemostatic system is very sensitive to the presence of any toxic substance in the circulation.

Hypothesis

It is generally believed that selenium and its compounds are antioxidants. This confusing notion stems from the observation that selenium is a cofactor in glutathione peroxidase, a biologically powerful antioxidant. It should be noted that the term “oxidation” is somewhat misleading because it does not always involve oxygen atoms. Simply, an oxidant is an atom and/or a molecule that accepts, and a reductant is such that donates electrons, respectively. Thus, selenium with tetravalent cation (Se<sup>4+</sup>) can accept two electrons to become divalent cation (Se<sup>2+</sup>) and this way act as an oxidant. This oxidizing capacity of selenium has important implications for its antiviral property. Selenium reacts readily with the sulphydryl groups in the active site of viral protein disulphide isomerase (PDI) converting them to inactive disulfide according to the following formula:

\[ \text{PDI} \rightarrow (\text{SH})_2 + \text{Se}^{4+} \rightarrow \text{PDI} - \text{SS} - \text{PDI} + \text{Se}^{2+} \]

In this way the viral hydrophobic spike loses its ability to undergo the exchange reaction with disulphide groups of cell membrane proteins and prevents virus entering to the healthy cell cytoplasm [12]. The same mechanism applies to the action of surface disinfection agents that contain oxidizing agents such as phenol, hydrogen peroxide, any hypochlorite [13]. It should be noted that selenium has been implicated as an important factor in aging and aging related diseases [14], and in the prevention of mammary cancer [15]. There also numerous reports describing the relationship between selenium and other diseases such as type 2 diabetes mellitus [16], asthma [17], and cardiovascular diseases [18,19]. Significance of selenium in human health was extensively reviewed by Brown & Arthur [20]. Apparently, these diseases are associated with the increased expression of the protein sulphydryl groups (-SH), which are then oxidized by selenium to inactive disulfides bonds (S-S).

In view of the facts mentioned above it seems logical to assume that sodium selenium could represent a potential agent for the prevention of viral infections including coronavirus, according to the mechanism suggested for the Ebola virus [21]. In the paper presented by Jayawardane [22], the authors stated that selenium supplementation inhibited the development of polio and influenza virus. Which also agrees with our hypothesis that selenium strengthens the immune system. This element increases the proliferation of natural killer (NK) cells. Selenium also has a positive effect in combination with some vitamins (D, E) as presented in the work Delesderrier et al. [23]. The combination of phytoncides found in onions along with selenium increased T lymphocyte proliferation [24]. In addition, selenium reduces the formation of thrombosis in the blood vessels. According to Fogarty [25], blood coagulation disorders leading to the formation of micro-clots are a significant cause of death in patients with COVID-19. We believe that the use of sodium selenium in anticoagulation therapy may reduce the risk of blood clots forming (formation of high-molecular polymer -paraffin) in patients with COVID-19 particularly at risk for its severe course. It should be mentioned that this chemical reagent is rather inexpensive and readily available. It is only unfortunately that physicians, having limited knowledge of this mineral, cannot understand that such a simple chemical substance can have such dramatic health effects.
