Comparative Hepatic and Intestinal Efflux Transport of Statins

Feng Deng, Suvi-Kukka Tuomi, Mikko Neuvonen, Päivi Hirvensalo, Sami Kulju, Christoph Wenzel, Stefan Oswald, Anne M. Filippula, and Mikko Niemi

ABSTRACT

Previous studies have shown that lipid-lowering statins are transported by various ATP-binding cassette (ABC) transporters. However, because of varying methods, it is difficult to compare the transport profiles of statins. Therefore, we investigated the transport of 10 statins or statin metabolites by six ABC transporters using human embryonic kidney cell-derived membrane vesicles. The transporter protein expression levels in the vesicles were quantified with liquid chromatography–tandem mass spectrometry and used to scale the measured clearances to tissue levels. In our study, apically expressed breast cancer resistance protein (BCRP) and P-glycoprotein (P-gp) transported atorvastatin, fluvastatin, pitavastatin, pravastatin, and rosuvastatin. Multidrug resistance-associated protein 3 (MRP3) transported atorvastatin, fluvastatin, pitavastatin, and, to a smaller extent, pravastatin. MRP4 transported fluvastatin and rosuvastatin. The scaled clearances suggest that BCRP contributes to 87%–91% and 84% of the total active efflux of rosuvastatin in the small intestine and the liver, respectively. For atorvastatin, the corresponding values for P-gp–mediated efflux were 43%–79% and 66%, respectively. MRP3, on the other hand, may contribute to 23%–26% and 25%–37% of total active efflux of atorvastatin, fluvastatin, and pitavastatin in jejunal enterocytes and liver hepatocytes, respectively. These data indicate that BCRP may play an important role in limiting the intestinal absorption and facilitating the biliary excretion of rosvastatin and that P-gp may restrict the intestinal absorption and mediate the biliary excretion of atorvastatin. Moreover, the basolateral MRP3 may enhance the intestinal absorption and sinusoidal hepatic efflux of several statins. Taken together, the data show that statins differ considerably in their efflux transport profiles.

SIGNIFICANCE STATEMENT

This study characterized and compared the transport of atorvastatin, fluvastatin, pitavastatin, pravastatin, rosuvastatin, and simvastatin acid and four atorvastatin metabolites by six ABC transporters (BCRP, MRP2, MRP3, MRP4, MRP8, P-gp). Based on in vitro findings and protein abundance data, the study concludes that BCRP, MRP3, and P-gp have a major impact in the efflux of various statins. Together with in vitro metabolism, uptake transport, and clinical data, our findings are applicable for use in comparative systems pharmacology modeling of statins.

Introduction

Cardiovascular diseases are among the most common causes of death, accounting for approximately 17.9 million deaths worldwide in 2015 (Roth et al., 2017). 3-Hydroxy-3-methylglutaryl coenzyme A reductase inhibitors, also known as statins, are first-line drugs for primary and secondary prevention of cardiovascular diseases. Statins inhibit mevalonate production mediated by 3-hydroxy-3-methylglutaryl coenzyme A reductase, which is a key step in cholesterol biosynthesis. Inhibition of this enzyme leads to a reduced cholesterol production and increased expression of low-density lipoprotein cholesterol receptors in the liver (Slater and MacDonald, 1988). Ultimately, this results in a reduction in low-density lipoprotein cholesterol and triglyceride levels accompanied by decreased mortality and coronary events (Maron et al., 2000). Statins may also exert beneficial effects through a cholesterol-independent, pleiotropic manner by reducing systemic inflammation and platelet hyper-reactivity and improving endothelial function (Liao and Laufs, 2005). Although statins are widely used and generally accepted as efficient and safe (Yebto et al., 2019), they may cause muscle toxicity ranging from mild and relatively common myalgia to rare but life-threatening rhabdomyolysis (Harper and Jacobson, 2007).

Drug transporters play a key role in regulating drug levels in systemic circulation and various tissues (Giacomini et al., 2010). These proteins are located on the plasma membranes of cells, where they either pump their substrates into the cytosol or out of the cell. ATP-binding cassette

ABREVIATIONS: ABC, ATP-binding cassette; AUC, area under the plasma concentration-time curve; BCRP, breast cancer resistance protein; CL, clearance; CLadj, expression-adjusted clearance; Km, Michaelis-Menten constant; LC-MS/MS, liquid chromatography–tandem mass spectrometry; MRP, multidrug resistance-associated protein; OATP, organic anion–transporting polypeptide; P-gp, P-glycoprotein; SCHH, sandwich-culture human hepatocyte; Vmax, maximal transport rate.
(ABC) transporters are efflux pumps that use ATP to expel their substrates out of cells. Besides numerous drugs and other xenobiotics, they have an important task of excreting endogenous metabolites and waste products. P-glycoprotein (P-gp) and breast cancer resistance protein (BCRP) are among the most important efflux transporters, and they are followed by bile salt export pump and multidrug resistance-associated protein 2 (MRP2) (Hillgren et al., 2013). These transporters are abundantly expressed on the apical cell membranes in various pharmacokinetically relevant tissues, such as the intestine, liver, kidney, and blood-brain barrier. There they limit the absorption and promote the elimination of a wide range of compounds. In contrast, the efflux transporters MRP3 and MRP4 are located on the basolateral cell membranes in the intestine and liver. These transporters pump their substrates toward systemic blood flow, thus promoting absorption and affecting the distribution of their substrates (van de Wetering et al., 2009; Kitamura et al., 2010a; Kitamura et al., 2010b).

In general, the statins have limited oral bioavailabilities due to marked first-pass loss (Neuvonen et al., 2006; Elsby et al., 2012). In the intestine, they are subject to biotransformation and apical efflux to gut lumen. In the liver, they are extensively transported into hepatocytes by organic anion–transporting polypeptides (OATPs), which are important determinants of systemic exposure and clearance of the statins (Niemi et al., 2011). However, statin transport by the efflux transporters located on basolateral membranes in the intestine and liver are less well characterized. Since these transporters may also regulate the intracellular statin concentrations, their role in statin pharmacokinetics should be characterized in more detail. Hence, the present study aimed to compare the transport of atorvastatin, atorvastatin metabolites, fluvastatin, pitavastatin, pravastatin, rosuvastatin, and simvastatin acid by different efflux transporters using a vesicular transport assay.

Materials and Methods

Materials. Atorvastatin, atorvastatin-d5, 2-hydroxyatorvastatin, 2-hydroxyatorvastatin-d5, 2-hydroxyatorvastatin lactone, 2-hydroxyatorvastatin lactone-d5, 4-hydroxyatorvastatin, 4-hydroxyatorvastatin-d5, 4-hydroxyatorvastatin lactone, 4-hydroxyatorvastatin lactone-d5, fluvastatin-d8, pitavastatin-d5, pravastatin, pravastatin-d9, rosuvastatin, rosuvastatin-d6, and simvastatin acid-d6 were purchased from Toronto Research Chemicals (Toronto, Canada). Racemic fluvastatin, 3R,5S-fluvastatin, 3S,5R-fluvastatin, and pitavastatin were obtained from Santa Cruz Biotechnology (Dallas, TX). Simvastatin acid was purchased from SynFine Research (Ontario, Canada). Vesicles made of human embryonic kidney 293 cells were purchased from PharmTox at the Radboud University Medical Center (PharmTox, Radboud UMC, Nijmegen, The Netherlands). Solvents used in assays and analytical methods were of analytical quality and purchased from Sigma-Aldrich (St. Louis, MO). Ultrapure water for assays and analyses was purified using Milli-Q water purification system (Merck Millipore, Burlington, MA).

Vesicular Transport Assay. Vesicular transport assay was used to examine statin transport. The assays were performed essentially as described previously (Lehtisalo et al., 2020). In brief, transport-expressing membrane vesicles (7.5 μg) were preincubated at 37°C for 10 minutes in transport assay buffer (PharmTox, Radboud UMC, Nijmegen, The Netherlands) supplemented with 10 mM MgCl₂ and various concentrations of statins. After the preincubation, the transport assay was started by adding prewarmed Mg-ATP solution (PharmTox, Radboud UMC, Nijmegen, The Netherlands). Samples were then transferred onto a MultiScreen HTS PB Filter Plate 1.0 mm/0.65 μm (Merck KGaA, Darmstadt, Germany), and the vesicles were washed thrice with 200 μl stop buffer and twice with ice-cold washing buffer (40 mM 4-morpholino-nepropanesulfonic acid/Tris pH 7.0 and 70 mM KCl). After washing, the filter wells were air-dried, and the statins were eluted from vesicles with 50% methanol containing 25 ng/ml of isotope-labeled statin as an internal standard.

All assays were performed in triplicates on 96-well plates.

Transport Studies. The vesicular transport assay and the function of membrane vesicles were verified by investigating the transport of estradiol-17-glucuronide and N-methyl-quinioline, known MRP and P-gp substrates, respectively. Statin transport was initially screened in BCRP, MRP2, MRP3, MRP4, P-gp, and control vesicles: 10 μM of atorvastatin, 3R,5S-fluvastatin, 3S,5R-fluvastatin, pitavastatin, pravastatin, and rosuvastatin and 1 μM of simvastatin acid were incubated with the vesicles for 10 minutes. In addition, the transport of 10 μM atorvastatin metabolites was screened similarly in BCRP, MRP2, MRP3, MRP4, P-gp, and control vesicles. Statin-transporter combinations that exhibited notably higher uptake in the presence of ATP compared with that in the absence of ATP were further studied for time-linear range of transport with incubation times of 5, 10, and 15 minutes. Finally, the concentration-dependent transport (transporter kinetics) for confirmed substrates was determined in at least three separate experiments, in which the statin concentration ranged from 6 to 200 μM. The incubation time (5 minutes) was selected based on the results of the time-dependence experiments. Racemic fluvastatin was employed in the kinetic studies, since the fluvastatin enantiomers exhibited no selectivity in the investigated transporters and racemic mixture was more readily available.

5′-Nucleotide Activity Assay. The 5′-nucleotide activity assay was used to determine the fraction of inverted membrane vesicles, essentially as described previously (Meszaros et al., 2011). In short, 15 μg of transporter membrane vesicles were incubated at 37°C for 30 minutes with and without 3 mM AMP and 0.3% Triton X-100 in 50 mM Tris-HCl (pH 7.4) and 4 mM MgCl₂. The inorganic phosphate generated from AMP by 5′-nucleotidase located on the extracellular side of the plasma membrane was measured using Malachite Green Phosphate Detection Kit (R&D Systems, Minneapolis, MN).

The 5′-nucleotidase activity was determined at four conditions: A) measurement with AMP and Triton X-100, which provides the maximum activity; B) measurement with AMP only, which provides the activity in right-side-out vesicles; C) measurement with Triton X-100 only, which shows the phosphate background in the presence of Triton X-100; and D) measurement without AMP and Triton X-100, which shows the background phosphate in the assay buffer.

\[
\text{Fraction inverted} = \frac{(A-C) - (B-D)}{A-C} \times 100\%
\]

The fraction of inverted membrane vesicles was calculated using eq. 1. In the equation, A, B, C, and D indicate the amount of inorganic phosphate at the four conditions described above. A – C describes the total activity of 5′-nucleotidase, whereas B – D describes the activity of 5′-nucleotidase in the right-side-out vesicles.

Analytical Methods. All statins and statin metabolites were analyzed using a Sciex 5500 Qtrap LC-MS/MS system (AB Sciex, Framingham, MA) interfaced with an ESI ion source. The chromatographic separation was performed on a Luna Omega polar C18 analytical column (100 × 2.1 mm i.d., 1.6 μm particle size; Phenomenex, Torrance, CA) protected by a guard column of the same material. The mobile phases A and B consisted of 5 mM ammonium formate (pH 3.9, adjusted with 98% formic acid) and acetonitrile, respectively, and the flow rate and the column temperature were maintained at 300 μl/min and 40°C. The following gradient conditions were applied: 1 minute at 20% B on hold, then a linear ramp from 20% B to 40% B over 3 minutes followed by a second linear ramp to 90% B over 2 minutes and 1 minute at 90% B before a re-equilibration step back to the initial conditions (20% B). The mass spectrometer was operated in multiple reaction monitoring mode, and the characteristic ion transitions for each analyte and internal standard are presented in Supplemental Table S1.

Protein amounts (pmol/mg of protein) of BCRP, MRP2, MRP3, MRP4, and P-gp in vesicles were quantified by mass spectrometry–based targeted proteomics using a validated LC-MS/MS method as described elsewhere (Griör et al., 2013; Oswalt et al., 2019). The isolated vesicles were subjected to determination of the whole protein concentrations using the BCA assay (Thermo Fisher Scientific, Schwerte, Germany). If necessary, membrane fractions were adjusted to a maximum protein amount of 2 mg/ml. Subsequently, the membrane vesicles were homogenized using a Tomy Ultraturrax homogenizer (Tomy, Japan) and the membrane protein content was determined using a BCA protein assay (Thermo Fisher Scientific, Schwerte, Germany).
Mannheim, Germany) and incubated for 20 minutes at 60°C. After cooling down, 10 μl iodoacetamide (400 mM, Sigma-Aldrich) were added, and the samples were incubated in a darkened water bath for 15 minutes at 37°C. For protein digestion, 10 μl trypsin (trypsin/protein ratio: 1/40, Promega) was added, and samples were incubated in a water bath for 16 hours at 37°C. Digestion was stopped by addition of 20 μl formic acid (10% v/v, Sigma-Aldrich). Afterward, the samples were centrifuged one more time for 15 minutes at 16,000 g and 4°C. Then 50 μl of the supernatant was mixed with 25 μl isotope-labeled internal standard peptide mix (10 nM of each labeled peptide, Thermo Fisher Scientific). All sample preparation and digestion steps were performed using Protein LoBind tubes (Eppendorf, Hamburg, Germany). Protein quantification was conducted on a 5500 QTRAP triple quadruple mass spectrometer (AB Sciex, Darmstadt, Germany) coupled to an Agilent Technologies 1260 Infinity system (Agilent Technologies, Waldbronn, Germany). Transporters were simultaneously quantified using proteospecific peptides. Final protein abundance data (picomoles per milligram) were calculated by normalization to the total protein content of the isolated membrane fraction as determined by the BCA assay.

**Data and Statistical Analysis.** ATP-dependent transport was calculated by subtracting the statin uptake into vesicles in the absence of ATP from the statin uptake into vesicles in the presence of ATP. Uptake ratio was determined by uptake of investigated statin into vesicles in the presence of ATP divided by that in the absence of ATP. The ATP-dependent transport and uptake ratios in screening and time-dependent transport studies were compared with those in control vesicles using one-way ANOVA and Fisher’s least significant difference analysis (GraphPad Software version 8.4, San Diego, CA). A P value below 0.05 was considered statistically significant.

The kinetic parameters of statin transport were determined with GraphPad Prism 8.4. For these calculations, the mean ATP-dependent transport values of each concentration point from separate experiments were pooled, and these values were fitted to the Michaelis-Menten equation (eq. 2), wherein $v$ stands for the velocity of ATP-dependent transport, $V_{\text{max}}$ stands for the maximal transport rate, $[S]$ stands for the substrate concentration, and $K_m$ stands for the Michaelis-Menten constant.

$$v = \frac{V_{\text{max}} [S]}{K_m + [S]} \quad (2)$$

The in vitro statin clearance was calculated from Michaelis-Menten parameters as shown in eq. 3.

$$CL_{\text{in vitro}} = \frac{V_{\text{max}}}{K_m} \quad (3)$$

The in vitro statin clearance was adjusted with vesicle protein expression as shown in eq. 4.

$$CL_{\text{adj}} = \frac{CL_{\text{in vitro}}}{\text{protein expression}} \times \text{fraction of membrane proteins} \quad (4)$$

in which $CL_{\text{adj}}$ stands for expression-adjusted clearance, Protein expression stands for transporter abundance measured in vesicles, and fraction of membrane proteins that is inverted. The clearance was further scaled to the tissue level by multiplying $CL_{\text{adj}}$ with published transporter abundance data (eq. 5).

$$CL_{\text{tissue}} = CL_{\text{adj}} \times \text{protein expression}_\text{tissue} \quad (5)$$

In eq. 5, $CL_{\text{tissue}}$ is the estimated tissue level efflux statin clearance, and $\text{protein expression}_\text{tissue}$ is the abundance of the efflux transporter in the tissue of interest (Burt et al., 2016; Drozdzik et al., 2019).

**Results**

**Transport of Known Substrates of MRP2, MRP3, MRP4, MRP8, and P-gp.** The functionalities of the vesicles were verified using estradiol-17-glucuronide (50 μM for MRP2; 5 μM for MRP3, MRP4, MRP8, and control vesicles) and N-methyl-quinidine (5 μM for P-gp) as positive controls. The uptake ratios of these probe substrates in MRP2, MRP3, MRP4, MRP8, and P-gp vesicles were 79, 38, 15, 2.8, and 2.4, respectively, verifying the functionality of the vesicles and vesicular transport assay (Supplemental Fig. S1).

**Screening of Statin Efflux Transport.** The screening of statin transport was conducted by incubating 10 μM of statins (or 1 μM in the case of simvastatin acid) with BCRP, MRP2, MRP3, MRP4, MRP8, P-gp, and control vesicles (Fig. 1; Supplemental Table S2). Atorvastatin was significantly transported by MRP3 (uptake ratio 2.2 ± 0.6) and P-gp (3.1 ± 0.6), and the uptake ratio of transport differed significantly from control (MRP3, $P = 0.0102$; P-gp, $P < 0.0001$). 3R,5S-fluvastatin was significantly transported by BCRP (3.8 ± 0.9, $P < 0.0001$) and P-gp (2.8 ± 0.3, $P = 0.0078$), whereas 3S,5R-fluvastatin was significantly transported by BCRP (3.1 ± 1.6, $P = 0.0497$), MRP3 (3.2 ± 1.0, $P = 0.0261$), and MRP4 (3.1 ± 0.8, $P = 0.0458$). Pitavastatin was clearly transported by BCRP (4.6 ± 0.6, $P = 0.0006$) and P-gp (3.3 ± 1.0, $P = 0.0306$), and rosuvastatin was efficiently transported by BCRP (8.4 ± 3.1, $P = 0.0002$). For pravastatin and simvastatin acid, none of the uptake ratios differed significantly from the control.

In addition, we tested the transport of 10 μM atorvastatin metabolites: 2-hydroxyatorvastatin, 4-hydroxyatorvastatin, 2-hydroxyatorvastatin lactone, and 4-hydroxyatorvastatin lactone in BCRP, MRP2, MRP3, MRP4, P-gp, and control vesicles. 2-Hydroxyatorvastatin was taken up in BCRP (uptake ratio 3.5 ± 0.9, $P = 0.0279$) and MRP3 (3.3 ± 0.6, $P = 0.0492$) vesicles significantly more than in control vesicles (uptake ratio 1.9 ± 0.7) (Fig. 1; Supplemental Table S3). The transport of 4-hydroxyatorvastatin in MRP3 (4.4 ± 1.5, $P = 0.0028$) and P-gp (4.0 ± 1.1, $P = 0.0076$) vesicles differed significantly from control vesicles (1.3 ± 0.7). The 2- and 4-hydroxyatorvastatin lactones showed no transport in any vesicles (Supplemental Table S3).

**Time-Dependent Transport.** The transport of statins by selected transporters was further investigated by studying the time-dependent transport (Supplemental Figs. S2–S7; Supplemental Tables S4–S5). In most cases, when notable transport was observed, the ATP-dependent transport plateaued already at 5 minutes as the statin uptake into vesicles and the escape of the statins due to passive diffusion reached equilibrium.

Atorvastatin transport was already prominent at 5 minutes in BCRP, MRP3, and P-gp vesicles with uptake ratios of 2.5 ($P = 0.0012$), 2.2 ($P = 0.0167$), and 2.5 ($P = 0.0019$), respectively, which were significantly higher than that in control vesicles (Supplemental Fig. S2). On the other hand, the ATP-dependent transport and uptake ratio in MRP2 and MRP4 vesicles did not differ from the control vesicles, except for MRP2 at 10-minute time point.

The transport rates of both fluvastatin enantiomers in BCRP, MRP3, and P-gp vesicles were significantly higher than those in control vesicles at any given time, and the ATP-dependent transport was nearly plateaued 5 minutes after initiation of transport (Supplemental Figs. S3 and S4). The 3R,5S-fluvastatin transport rate in MRP2 and MRP4 vesicles was higher than that in control vesicles at 5 and 10 minutes. The 3S,5R-fluvastatin transport rate in MRP2 and MRP4 vesicles was higher than that in control vesicles only at 10 minutes. The transport rates of 3R,5S-fluvastatin and 3S,5R-fluvastatin in MRP8 vesicles differed significantly from those of control vesicles only at 5- and 10-minute time points, respectively.

Pitavastatin was transported by BCRP with high efficiency: The transport rates in BCRP vesicles were three times higher than those in MRP3 and P-gp vesicles (Supplemental Fig. S5). The transport rates in MRP3 vesicles were significantly higher than those of control at 5- and 15-minute time points, but only at 15 minutes the uptake ratio of 2.3 was significantly greater than in control vesicles ($P = 0.0011$). P-gp vesicles showed significantly higher transport rate ($P = 0.0002$) and the uptake ratio (3.6, $P = 0.0004$) at 5-minute time point than control vesicles.
In the screening, the uptake ratios of pravastatin were relatively high in BCRP, MRP3, and MRP4 vesicles, although they did not differ significantly from that of control vesicles. For this reason, the time-dependent transport of pravastatin was further studied. MRP3 exhibited low yet significant transport rates at 5-minute ($P = 0.0050$) and 15-minute ($P = 0.0115$) time points despite notable variation (Supplemental Fig. S6). In addition, the uptake ratio at 5 minutes (2.2, $P = 0.0018$) was significantly greater than that of control. Pravastatin transport rates in BCRP, MRP2, and MRP4 vesicles did not differ significantly from control, except for MRP2 at 15 minutes ($P = 0.0473$).

Rosuvastatin was transported by BCRP with high rate and uptake ratio at any given time, although the ATP-dependent transport plateaued already at 5 minutes (Supplemental Fig. S7). Although the MRP4 and P-gp transported rosuvastatin to some extent, the transport rates did not differ significantly from control vesicles and were approximately an order of magnitude lower than those in BCRP vesicles. Only the transport rate at 10 minutes in MRP4 vesicles was significantly greater than that in control vesicles ($P = 0.0410$). The high uptake ratio of rosuvastatin in MRP8 vesicles in screening studies was not replicated in the time-dependence studies.

The time-dependent transport of simvastatin acid was not further investigated, as the uptake ratios of simvastatin acid transport in the screening were relatively close to that in control vesicles.

Concentration-Dependent Transport (Transporter Kinetics). Based on atorvastatin screening and time-dependence studies, BCRP, MRP3, and P-gp were selected for kinetic measurements (Fig. 2). Atorvastatin had apparent affinities of 82.4, 31.5, and 10.7 μM in BCRP, MRP3, and P-gp, respectively (Table 1). The maximum transport rate in the investigated transporters followed the same order, with the rate being the greatest for BCRP and the lowest for P-gp.

Racemic fluvastatin was employed in kinetic studies, since the enantiomers exhibited no distinct selectivity in the investigated transporters, and racemic mixture is more readily available. Racemic fluvastatin was well transported by BCRP and MRP3 with similarly high affinities (K_m...
uptake ratio of 12

The MRP3-mediated transport of pitavastatin was less clear as the BCRP vesicles was four times higher than in other vesicles (Table 1). Over the concentration range. Furthermore, the clearance of pravastatin was notably lower in control vesicles than in other vesicles. Furthermore, the uptake ratio in three control experiments was on average 1.26 ± 0.44 and 2.39 ± 0.15, whereas the uptake ratio of MRP2 and P-gp, which had lowest ratio and highest deviation, respectively, were 1.81 ± 0.44 and 2.93 ± 1.09 (Supplemental Table S6).

The apparent affinities of pitavastatin in BCRP, MRP3 and P-gp vesicles were high and relatively similar across the transporters (16, 9.0, and 37 μM, respectively, Fig. 4). The maximum rate of transport in BCRP vesicles was four times higher than in other vesicles (Table 1). The MRP3-mediated transport of pitavastatin was less clear as the uptake ratio of 12 μM pitavastatin in MRP3 vesicles remained below two (1.8 ± 0.2).

Pravastatin was transported in MRP3 vesicles only (Fig. 5). In the kinetic studies, pravastatin transport exhibited nonsaturable transport over the concentration range. Furthermore, the clearance of pravastatin was notably lower compared with the clearance of other statins in MRP3 (Table 1).

Rosuvastatin is a well established BCRP substrate with high transport rate and apparent affinity of transport. This was confirmed in our study with a single experiment, which concluded that Km of rosuvastatin transport in BCRP was approximately 4.2 μM (Fig. 6). Meanwhile the apparent affinities of rosuvastatin in MRP4 and P-gp vesicles were 10-fold lower (Km of 39.3 and 46.2 μM, respectively). However, their transport rates in the presence of high concentrations of rosuvastatin showed large variability, which leads to the unreliable estimation of Michaelis-Menten parameters.

5'-Nucleotidase Activity and the Fraction of Inverted Membrane Vesicles. The fraction of inverted membrane vesicles was determined using the 5'-nucleotidase activity assay (Supplemental Fig. S8). The f\text{inverted} of BCRP, MRP2, MRP4, MRP8, and P-gp vesicles were similar (36%–52%), whereas the f\text{inverted} of MRP3 vesicles was higher (65%).

Proteomic Measurements of Membrane Vesicles and the Estimation of Tissue-Specific Active Efflux Clearance. The transporter abundance in vesicle preparations was measured with a quantitative proteomic technique based on LC-MS/MS. The absolute abundances in BCRP, MRP2, MRP3, MRP4, and P-gp vesicles were 146, 85, 54, 44, and 59 pmol/mg of protein, respectively (Supplemental Table S7).

**TABLE 1**

The summary of kinetic parameters and expression-adjusted clearance of atorvastatin, racemic fluvastatin, pitavastatin, pravastatin, and rosuvastatin transport in BCRP, MRP2, MRP3, MRP4, MRP8, and P-gp vesicles.

| Statin      | Transporter | V_{max} (95% CI) pmol/min/mg | K_m (95% CI) μM | CL_{in} nl/min/pmol of transporter | CL_{adj} nl/min/mg |
|------------|-------------|-----------------------------|----------------|-----------------------------------|-------------------|
| Atorvastatin | BCRP        | 135 (92.3–258)              | 82.4 (34.05–249) | 1.6                              | 30.8              |
|            | MRP3        | 77.0 (57.7–114)             | 31.5 (12.3–84.2) | 2.4                              | 68.7              |
|            | P-gp        | 32.9 (27.3–40.0)            | 10.7 (4.34–23.1) | 3.1                              | 133               |
| Fluvastatin | BCRP        | 408 (313–580)               | 25.8 (9.81–68.4) | 15.8                             | 298               |
|            | MRP2        | 105 (45.2–infinity)         | 54.0 (1.92–infinity) | 1.9                         | 49.9               |
|            | MRP3        | 170 (77.1–infinity)         | 48.9 (2.12–infinity) | 3.5                         | 97.6               |
|            | MRP4        | 54.7 (23.4–4053)           | 31.8 (0–infinity)    | 1.7                             | 76.4               |
|            | MRP8        | 74.5 (41.6–580)            | 73.0 (10.5–1524)     | 1.0                             | n/a               |
|            | P-gp        | 169 (51.6–infinity)        | 282 (21.3–infinity)     | 0.6                             | 25.8               |

Based on the in vitro results, 5'-nucleotidase activity data, proteomics measurements, and published transporter abundance data from literature, we calculated the expression-adjusted clearance, $CL_{adj}$, (Table 1), and the individual contribution of efflux transporters to the total active efflux clearance in various tissues (Fig. 7; Supplemental Table S8). For atorvastatin, fluvastatin, and pitavastatin, basolateral pumps were estimated to

Fig. 3. Concentration-dependent transport of fluvastatin in BCRP, MRP2, MRP3, MRP4, MRP8, P-gp, and control vesicles. The time of incubation and vesicle amount were 5 minutes and 7.5 μg, respectively. Results are presented as mean ± S.D. transport, which is calculated from the means of each separate experiment. In total, three separate experiments were performed for each transporter with triplicate samples in each experiment.

Fig. 4. Concentration-dependent transport of pitavastatin in BCRP, MRP3, P-gp, and control vesicles. The time of incubation and vesicle amount were 5 minutes and 7.5 μg, respectively. Results are presented as mean ± S.D. transport, which is calculated from the means of each separate experiment. In total, three separate experiments (two for control vesicles) were performed for each transporter with triplicate samples in each experiment.
contribute to approximately 50% and 28% of their efflux clearance in duodenal and jejunal enterocytes, respectively. Although the contribution of these transporters diminishes in the ileum, it still remains notable (approximately 15%). Similarly in the hepatocytes, basolateral efflux, primarily mediated by MRP3, was estimated to contribute to one-third of the total known hepatic efflux of these statins. The scaled efflux clearance estimation underlines the impact of BCRP in rosuvastatin efflux, wherein over 84% of efflux clearance in both the intestine and liver was estimated to be mediated by BCRP. For atorvastatin, P-gp was estimated to comprise nearly 90% of its apical efflux clearance. Its role is particularly evident in the liver, in which P-gp is much more abundant than BCRP.

Discussion

In the present study, we evaluated the transport of six statins by six efflux transporters relevant for drug absorption, distribution, and elimination. This study is unique in that the transport was studied using uniform methods in a single laboratory, thus allowing comparison of statin efflux profiles. Of the apical efflux transporters tested, BCRP and P-gp transported atorvastatin, fluvastatin, pitavastatin, and rosuvastatin, and MRP2 transported fluvastatin. Interestingly, atorvastatin, fluvastatin, pitavastatin, and pravastatin were transported by the basolaterally expressed MRP3 and fluvastatin and rosuvastatin were expressed by MRP4. Simvastatin acid was not transported by any of the investigated transporters. This could be due to high passive permeability, which may result in a false negative result in the vesicular transport assay.

Furthermore, kinetic parameters from membrane vesicle assays combined with protein expression data, allowed the scaling of the obtained findings to tissue level. Taken together, our data indicate that statins differ in their efflux transport profiles.

BCRP, MRP2, and P-gp are expressed on the apical plasma membranes in tissues important for pharmacokinetics. There, they limit the absorption and facilitate the excretion of their substrates. Previous pharmacogenetic studies have suggested that BCRP restricts the intestinal absorption of atorvastatin, fluvastatin, and rosuvastatin (Keskitalo et al., 2009b,c). Indeed, we observed extensive BCRP-mediated transport of fluvastatin, pitavastatin, and rosuvastatin, and minor but significant transport of atorvastatin. The more lipophilic pitavastatin and especially atorvastatin were good P-gp substrates, whereas the hydrophilic rosuvastatin was poorly transported by P-gp. Interestingly, all the statins transported by P-gp contain at least one nitrogen atom, which could be beneficial when interacting with the negatively charged binding cavity of P-gp (Deng et al., 2020).

MRP3 and MRP4 are expressed on the basolateral plasma membrane in small intestine and liver (Drozdzik et al., 2019). According to a recent meta-analysis, the hepatic abundance of MRP3 in healthy Caucasian adults is similar to that of P-gp and 40% lower than that of MRP2 (Burt et al., 2016). Furthermore, when all the ethnicities and disease states were included in the meta-analysis, the hepatic abundance of MRP4 was 70% lower than that of MRP3 and similar to the level of BCRP. In the enterocytes, they may facilitate the vectorial movement of their substrate drugs and metabolites by flipping them from the enterocyte to mesenteric blood (van de Wetering et al., 2009; Kitamura et al., 2010a; Kitamura et al., 2010b; Proctor et al., 2016). Our estimations of active efflux clearance suggest that this basolateral pathway may be important for the absorption of several statins (Fig. 7). In the liver, statins are actively taken into the hepatocytes by OATP1B1, OATP1B3, and OATP2B1 (Bi et al., 2019). MRP3 and MRP4 may partly counteract this by returning statins from hepatocytes back to the sinusoidal blood. We hypothesize that basolateral transporters may additionally promote statin elimination and pharmacological activity by distributing statins and their metabolites more evenly in the hepatocytes along the sinusoids. This hepatocyte shunting could prevent the saturation of the pharmacological target, metabolic enzymes, and biliary efflux transporters (Jusuf et al., 2012). Based on our scaled clearance values, MRP3 could affect the intracellular statin efflux and enable hepatocyte shuffle for statins.

Atorvastatin is a lipophilic statin with an oral bioavailability of 14%, which is explained by first-pass hepatic extraction (Lennernäss, 2003). Here, the transport kinetics of atorvastatin and its metabolites were determined for the first time using membrane vesicles. The highest affinity and abundance-scaled clearance of atorvastatin were observed...
in P-gp vesicles. The estimated tissue-specific efflux clearances indicate that P-gp, and BCRP to a smaller extent, could regulate atorvastatin plasma and tissue levels in humans. In line with this, previous studies have demonstrated increased systemic exposure to atorvastatin in association with genetic variants, which reduce the function or expression of the P-gp and BCRP (Keskitalo et al., 2008; Keskitalo et al., 2009c; León-Cachón et al., 2016). Moreover, our findings suggest that MRP3 may facilitate the intestinal absorption of atorvastatin especially in the jejunum and the hepatocyte hopping of atorvastatin and its metabolites. Moreover, MRP3 could be an important basolateral pathway for 2-
hydroxysterovastatin, which is extensively formed in the liver (Lau et al., 2006).

Fluvastatin is a relatively lipophilic statin but has a low bioavailability of 29% partly due to extensive first-pass hepatic metabolism (Tse et al., 1992). In the kinetic experiments, the highest transport rate and affinity were observed in BCRP vesicles, whereas the lowest affinity was seen in P-gp vesicles. We also demonstrated for the first time that fluvastatin is transported in MRP2, MRP3, MRP4, and MRP8 vesicles. Our scaled efflux clearance values suggest that the BCRP plays a major role in the apical efflux of fluvastatin in the intestine, whereas both MRP2 and BCRP may be important for the biliary clearance. In humans, a reduced-function genetic variant of BCRP was associated with increased exposure to fluvastatin (Keskitalo et al., 2009b). Furthermore, rat data support a role for MRP2 in fluvastatin biliary excretion (Lindahl et al., 2004), although observations in preclinical species must be treated with caution. Based on the scaled tissue efflux clearances, MRP3 and MRP4 could promote the intestinal absorption of fluvastatin. Together, MRP3 and MRP4 constitute 22%–53% of the total intestinal efflux clearance, depending on the site along the small intestine. In the hepatocytes, MRP3 and MRP4 may account for over 31% of the total efflux clearance and could thus enable fluvastatin hepatocyte hopping. Interestingly, fluvastatin was the sole substrate for MRP8 in our study. However, the impact of MRP8 remains elusive, since its membrane localization, abundance, and function are poorly characterized.

Pitavastatin is a lipophilic and metabolically stable statin that undergoes enterohepatic circulation, which explains its relatively high bioavailability of 51% and long half-life of 13 hours (Livalo Labeling Package Insert., 2009; Saito, 2011). In the present study, BCRP and goes enterohepatic circulation, which explains its relatively high bio-

localization, abundance, and function are poorly characterized. However, the impact of MRP8 remains elusive, since its membrane localization, abundance, and function are poorly characterized.

Pitavastatin is a lipophilic and metabolically stable statin that undergoes enterohepatic circulation, which explains its relatively high bioavailability of 51% and long half-life of 13 hours (Livalo Labeling Package Insert., 2009; Saito, 2011). In the present study, BCRP and MRP3 transported pitavastatin with a similar affinity and scaled clearance, which was followed by P-gp with 2-fold lower affinity and clearance. Thus, we estimate that BCRP may comprise the majority of intestinal apical efflux, whereas BCRP and P-gp are equally important in its biliary clearance in hepatocytes. These estimations agree with the mechanistic modeling of pitavastatin disposition in sandwich-cultured human hepatocytes (SCHHs) (Vildhede et al., 2016). However, despite being a good BCRP substrate in vitro (Fujino et al., 2005; Hirano et al., 2005b), the pharmacokinetics of pitavastatin have not been affected by genetic variants of BCRP (Ieri et al., 2007; Oh et al., 2013; Zhou et al., 2013). By contrast, a genetic variant of P-gp has been associated with increased Cmax and AUC of pitavastatin (Zhou et al., 2013). The scaled MRP3-mediated efflux clearance exceeded that of BCRP by 2-fold in the liver and was equal in jejunum. This agrees with data from the earlier SCHH study (Vildhede et al., 2016). Therefore, MRP3 could facilitate pitavastatin absorption. In a previous study, the accumulation of pitavastatin into the liver was reduced in Mrp2-deficient rats (Hirano et al., 2005b). Interestingly, the expression of Mrp3 is induced in these rats, supporting the importance of Mrp3 in the intrahepatic distribution of pitavastatin (Ogawa et al., 2000; Kuroda et al., 2004).

Pitavastatin is a hydrophilic statin with a low bioavailability (18%) limited by acid-catalyzed biotransformation (Singhvi et al., 1990) and hepatic uptake (Niemi et al., 2006b). This is the first study to demonstrate that pravastatin is a substrate of MRP3. In fact, MRP3 was the only transporter, which transported pravastatin in our study. Our data may explain how pravastatin is transferred from enterocytes to the mesenteric vein, and effluxed from hepatocytes back to the circulation. Surprisingly, we observed no pravastatin transport in either human embryonic kidney-MRP2 or S9-MRP2 vesicles (Supplemental Fig. S9), even though previous studies have suggested that MRP2 is a key canalicultransporter for pravastatin (Niemi et al., 2005a; Nakagomi–Hagihara et al., 2007; Elsby et al., 2011). In Mrp2-deficient rats, prava-

statin Cmax and AUC were increased compared with wild-type rats (Kivistö et al., 2005), which might be explained by the increased hepatic Mrp3 expression. Instead of MRP2, bile salt export pump could mediate the biliary excretion of pravastatin (Hirano et al., 2005a).

Rosuvastatin is another hydrophilic statin with a low bioavailability (20%), minimal metabolism, and a long terminal half-life of 20 hours (Neuvonen et al., 2006). Of the statins tested in our study, BCRP transported rosvastatin with the highest affinity and clearance. In contrast, minimal transport of rosvastatin was observed in P-gp and MRP4 vesicles. Our findings suggesting an important role for BCRP in the hepatic and intestinal efflux of rosvastatin are consistent with clinical data showing over 2-fold increase in the Cmax and AUC of rosvastatin in healthy volunteers homozygous for a genetic defect in BCRP (Keski-

talo et al., 2009c). The scaled clearance values imply that P-gp plays a limited role in rosvastatin efflux, a finding supported by clinical pharma
c
cogenetic data (Keskitalo et al., 2009a; Bai et al., 2019). Because of its hydrophilic nature, rosvastatin may require basolateral efflux transporters in absorption and distribution. MRP4 could facilitate rosvasta
tin absorption in the duodenum, where it was estimated to contribute 10% of rosvastatin efflux clearance. Rat liver perfusion and SCHH studies have demonstrated significant basolateral efflux of rosvastatin in the liver (Pfeifer et al., 2013a,b), but in our estimations, the role of hepatic MRP4 was minimal because of low in vitro activity and hepatic expression (Burt et al., 2016).

In conclusion, we compared the transport of atorvastatin, fluvastatin, pitavastatin, pravastatin, rosuvastatin, and simvastatin acid in BCRP, MRP2, MRP3, MRP4, MRP8, and P-gp vesicles. Using the vesicular transport assay and LC-MS/MS–based protein abundance measurements, we demonstrated the different efflux transport profiles and estimated the efflux clearances of statins in small intestine and liver. Because of assay variability in kinetic studies for certain statins and transporters, the estimated relative contributions of the different transporters to tissue efflux clearance should be interpreted with caution. Moreover, polarized-cell-monolayer–based or other alternative methods may be useful to confirm our findings. Overall, the present data can be applied to physiologically based pharmacokinetic or systems pharmacology modeling of statins.

Supplementary table S2: Summary of screening results. The mean and SD of uptake in the presence (+ATP) and absence of ATP (-ATP), ATP-dependent transport, and ratio of statin uptake between +ATP and −ATP from each transport-statin combination were obtained from a single experiment, performed with triplicate samples. One-way ANOVA was performed to evaluate the transport rates and the uptake ratio compared to control. * p < 0.05, ** p < 0.01.

| Statin        | Transporter | +ATP (pmol/mg) | -ATP (pmol/mg) | ATP-dependent transport (pmol/min/mg) | Uptake ratio of +ATP / -ATP | SD | SD |

Supplementary table S3: Summary of atorvastatin metabolite transport. The mean and SD of uptake in the presence (+ATP) and absence of ATP (-ATP), ATP-dependent transport and ratio between +ATP and −ATP from each transport-metabolite combination were obtained from a single experiment, performed with triplicate samples. One-way ANOVA was performed to evaluate the transport rates and the uptake ratio compared to control. * p < 0.05, ** p < 0.01

| Metabolite | Transporter | +ATP (pmol/mg) | -ATP (pmol/mg) | ATP-dependent transport (pmol/min/mg) | Uptake ratio of +ATP / -ATP |

Supplementary table S5: Summary of screening results. The mean and SD of uptake in the presence (+ATP) and absence of ATP (-ATP), ATP-dependent transport and ratio between +ATP and –ATP from each transport-statin combination studied were obtained from a single experiment, performed with triplicate samples. Two-way ANOVA was performed to evaluate the transport rate and uptake ratio compared to control. * p < 0.05, ** p < 0.01

| Statin  | Transporter | ATP-dependent transport at 5 min (pmol/min/mg) | SD | Ratio of +ATP / -ATP at 5min SD | ATP-dep. transport at 10 min SD | Ratio at 10 min SD | ATP-dep. transport at 15 min SD | Ratio at 15 min SD |

^A^: Sohlenius-Sternbeck A. K. (2006). Determination of the hepatocellularity number for human, dog, rabbit, rat and mouse livers from protein concentration measurements. Toxicology in vitro: an international journal published in association with BIBRA, 20(8), 1582–1586.
Supplementary figure S1: The transport of estradiol-17-glucuronide (E$_2$-17G) and N-methyl-quinidine (NMQ) in MRP2, MRP3, MRP4, MRP8, P-gp, and control vesicles. A single transport experiment performed with triplicate samples was conducted to verify the function of each membrane vesicle preparation. The amount of vesicles was 7.5 µg in every experiment. The concentration and incubation time of E$_2$-17G was 50 µM and 5 min, respectively for MRP2 vesicles, and 10 µM and 10 minutes, respectively, for MRP3, MRP4, MRP8, and control vesicles. The concentration and incubation time of NMQ was 5 µM and 5 min, respectively. A) The uptake of E$_2$-17G into the MRP2, MRP3, MRP4 and control vesicles in presence (+ATP) and absence (-ATP) of ATP is presented as mean ± SD. B) The uptake of E$_2$-17G in a separate experiment into the MRP8 and control vesicles in presence (+ATP) and absence (-ATP) of ATP is presented as mean ± SD. C) The uptake of NMQ in into the P-gp and control vesicles in presence (+ATP) and absence (-ATP) of ATP is presented as mean ± SD. Arbitrary units of NMQ uptake stands for the ratio between the peak area of NMQ and internal standard.
Supplementary figure S2: The time-dependent transport of atorvastatin in BCRP, MRP2, MRP3, MRP4, P-gp, and control vesicles. Substrate concentration, maximum time of incubation, and vesicle amount were 10 μM, 15 min, and 7.5 μg, respectively. Results are presented as mean ± SD ATP-dependent transport obtained from a single experiment, performed with triplicate samples. One-way ANOVA and uncorrected Fisher’s LSD analysis were performed to evaluate the transport rate in transporter of interest compared to control. * p < 0.05, ** p < 0.01.
Supplementary figure S3: The time-dependent transport of 3R,5S-fluvastatin in BCRP, MRP2, MRP3, MRP4, MRP8, P-gp, and control vesicles. Substrate concentration, maximum time of incubation, and vesicle amount were 10 µM, 15 min, and 7.5 µg, respectively. Results are presented as mean ± SD ATP-dependent transport obtained from a single experiment, performed with triplicate samples. One-way ANOVA and uncorrected Fisher’s LSD analysis were performed to evaluate the transport rate in transporter of interest compared to control. * p < 0.05, ** p < 0.01.
Supplementary figure S4: The time-dependent transport of 3S,5R-fluvastatin in BCRP, MRP2, MRP3, MRP4, MRP8, P-gp, and control vesicles. Substrate concentration, maximum time of incubation, and vesicle amount were 10 µM, 15 min, and 7.5 µg, respectively. Results are presented as mean ± SD ATP-dependent transport obtained from a single experiment, performed with triplicate samples. One-way ANOVA and uncorrected Fisher’s LSD analysis were performed to evaluate the transport rate in transporter of interest compared to control. * p < 0.05, ** p < 0.01.
Supplementary figure S5: The time-dependent transport of pitavastatin in BCRP, MRP2, MRP3, MRP8, P-gp, and control vesicles. Substrate concentration, maximum time of incubation, and vesicle amount were 10 µM, 15 min, and 7.5 µg, respectively. Results are presented as mean ± SD ATP-dependent transport obtained from a single experiment, performed with triplicate samples. Note the different y-axis of the BCRP subfigure. One-way ANOVA and uncorrected Fisher’s LSD analysis were performed to evaluate the transport rate in transporter of interest compared to control. The transport in BCRP, MRP3, MRP8, and P-gp vesicles was compared to control A, and MRP2 experiment, which was performed on a separate occasion, was compared to control B. * p < 0.05, ** p < 0.01.
Supplementary figure S6: The time-dependent transport of pravastatin in BCRP, MRP2, MRP3, MRP4, and control vesicles. Substrate concentration, maximum time of incubation, and vesicle amount were 10 µM, 15 min, and 7.5 µg, respectively. Results are presented as mean ± SD ATP-dependent transport obtained from a single experiment, performed with triplicate samples. One-way ANOVA and uncorrected Fisher’s LSD analysis were performed to evaluate the transport rate in transporter of interest compared to control. * p < 0.05, ** p < 0.01.
Supplementary figure S7: The time-dependent transport of rosuvastatin in BCRP, MRP2, MRP4, MRP8, P-gp and control vesicles. Substrate concentration, maximum time of incubation, and vesicle amount were 10 µM, 15 min, and 7.5 µg, respectively. Results are presented as mean ± SD ATP-dependent transport obtained from a single experiment, performed with triplicate samples. Note the different y-axis of the BCRP subfigure. One-way ANOVA and uncorrected Fisher’s LSD analysis were performed to evaluate the transport rate in transporter of interest compared to control. * p < 0.05, ** p < 0.01.
Supplementary figure S8: The fraction of inverted membrane vesicles ($f_{\text{inverted}}$) in BCRP, MRP2, MRP4, MRP8, P-gp and control vesicle preparations. Results are presented as mean ± SD obtained from a single experiment, performed with triplicate samples.
Supplementary figure S9: The transport of 50 µM E₂-17G (panel A) and 10 µM pravastatin (panel B). Compounds of interest were incubated with membrane vesicles supplemented with 3 mM glutathione in the presence and absence of 4 mM ATP for 10 minutes. Sf9 vesicles were generated from the Sf9 insect cells expressing the human recombinant MRP2 or defective mutant of MRP3 (control) (Järvinen et al. 2019). Solvo-MRP2-HEK and Solvo-Control-HEK vesicles were purchased from Solvo Biotechnology (Szeged, Hungary) and HEK-MRP2 from PharmTox at the Radboud University Medical Center (PharmTox, Radboud UMC, Nijmegen, The Netherlands). Results are presented as mean ± SD uptake in the presence (+ATP) and absence (-ATP) of ATP obtained from a single experiment, performed with triplicate samples.
