Abstract.
Observations suggest that twisted magnetic flux tubes are ubiquitous in the Sun’s atmosphere. The main aim of this work is to advance the study of axisymmetric modes of magnetic flux tubes by modeling both twisted internal and external magnetic field, when the magnetic twist is weak. In this work, we solve the derived wave equations numerically assuming twist outside the tube is inversely proportional to the distance from its boundary. We also study the constant magnetic twist outside the tube and solve these equations analytically. We show that the solution for a constant twist outside the tube is a good approximation to the case where the magnetic twist is proportional to $1/r$, namely the error is in all cases less than 5.4%. The solution is in excellent agreement with solutions to simpler models of twisted magnetic flux tubes, i.e. without external magnetic twist.

It is shown that axisymmetric Alfvén waves are naturally coupled with magnetic twist as the azimuthal component of the velocity perturbation is nonzero. We compared our theoretical results with observations and comment on what the Doppler signature of these modes is expected to be. Lastly, we argue that the character of axisymmetric waves in twisted magnetic flux tubes can lead to false positives in identifying observations with axisymmetric Alfvén waves.

1. Introduction

There is ample evidence of twisted magnetic fields in the solar atmosphere and below. For instance, it has been suggested that magnetic flux tubes are twisted whilst rising through the convection zone (see for example Murray & Hood 2008; Hood et al. 2009; Luoni et al. 2011; Brown et al. 2003; Yan & Qu 2007; Kazachenko et al. 2009) have shown that sunspots exhibit a relatively uniform rotation which in turn twists the magnetic field lines emerging from the umbra. Several studies argue that the chromosphere is also permeated by structures that appear to exhibit torsional motion (De Pontieu et al. 2012; Sekse et al. 2013). These structures, known as type II spicules, were initially identified by De Pontieu et al. (2007). De Pontieu et al. (2012) show that spicules exhibit a dynamical behavior that has three characteristic components, i) flows aligned to the magnetic field, ii) torsional motion and iii) what the authors describe as swaying motion.

Also, recent evidence shows that twist and Alfvén waves present an important mechanism of energy transport from the photosphere to the corona (Wedemeyer-Böhm et al. 2012). The increasing body of observational evidence of magnetic twist in the solar atmosphere, in combination with ubiquitous observations of sausage waves (Morton et al. 2012), reinforce the importance of refining our theoretical understanding of waves in twisted magnetic and especially axisymmetric modes as these could be easily perceived as torsional Alfvén waves.

Early studies of twisted magnetic flux tubes focused on stability analyses. For example, Shafranov (1957) investigated the stability of magnetic flux tubes with azimuthal component of magnetic field proportional to $r$ inside the cylinder and no magnetic twist outside. Kruskal et al. (1958) derived approximate solutions for magnetic flux tubes with no internal twist embedded in an environment with $B_z \propto 1/r$. Bennett et al. (1999) obtained solutions for the sausage mode for stable uniformly twisted magnetic flux tubes with no external twist and Erdélyi & Fedun (2006) extended the analysis for the incompressible case of constant twist outside the flux tube. The authors also examined the impact of twist on the oscillation periods in comparison to earlier studies (e.g. Edwin & Roberts 1983) considering magnetic flux tubes with no twist. In a subsequent work Erdélyi & Fedun (2007) extended their results in Erdélyi & Fedun (2006) to the compressible case for the sausage mode with no twist outside the tube. Karami & Bahari (2010) investigated modes in incompressible flux tubes. The twist was considered to be $\propto r$ for all $r$, which is unphysical for $r \to \infty$, while the density profile considered was piecewise constant with a linear function connecting the internal and external densities. The authors revealed that the wave frequencies for the kink and fluting modes are directly proportional to the magnetic twist. Also, the bandwidth of the fundamental kink body mode increases proportionally to the magnetic twist. Terradas & Goossens (2012) investigated twisted flux tubes with magnetic twist localized within a toroidal region of the flux tube and zero everywhere else. Terradas & Goossens (2012) argue that for small twist the main effect of standing oscillations is the change in polarization of the velocity wave function. The authors also considered the case where the twist is weak and analytically solved for the magnetic field structure and the oscillations.
perturbation in the plane perpendicular to the longitudinal dimension ($z$-coordinate).

In this work we study axisymmetric modes, namely eigenmodes corresponding to $k_z = 0$, where $k_z$ is the azimuthal wavenumber in cylindrical geometry\footnote{ $k_z$ is often denoted as $m$ in a number of other works.}. The azimuthal magnetic field inside the tube is $\propto r$, while the azimuthal field outside is constant. If there is a current along the tube, according to the Biot-Savart law this current will give rise to a twist proportional to $r$ inside the flux tube and a twist inversely proportional to $r$ outside. For this reason we start our analysis by assuming a magnetic twist outside the tube proportional to $1/r$ and we insert a perturbation parameter that can be used to revert to the case with constant twist. Subsequently, we present an exact solution for the case with constant twist outside the tube and solve numerically for the case with magnetic twist proportional to $1/r$. Then, we compare the numerical solution for $1/r$ with the exact solution for constant twist. Based on the obtained estimated standard error the solution corresponding to weak constant twist appears to be a good approximation to the solution with weak magnetic twist that is proportional to $1/r$. In the case where there is a pre-existing twist inside the cylinder, assuming this twist is uniform, this will give rise to a current which in turn will create the external twist that is again inversely proportional to the distance from the cylinder. The latter case may occur, for example, due to vortical foot-point motions on the photosphere (Ruderman et al. 1997). Recent observational evidence (e.g. Morton et al. 2013) put the assumptions of Ruderman et al. (1997) on a good basis, however, the vortical motions in Morton et al. (2013) are not divergence free which means that the same mechanism can be responsible for the axisymmetric modes studied in this work.

The rest of this paper is organized as follows. In Section 2 we describe the model geometry and MHD equations employed. In Section 3 we derive the dispersion relation for $k_z = 0$, and, in Section 3.3 we explore limiting cases connecting the results in this work with previous models. Furthermore, in Section 4 we study a number of physically relevant cases and elaborate on the results. In, Section 5 we reflect on the applicability and potential limitations of the presented model and in Section 6 we summarize and conclude this work.

**2. Model Geometry and Basic Equations**

The single-fluid linearized ideal MHD equations in the force formalism are (Kadomtsev 1966),

$$\frac{\partial^2 \delta \xi}{\partial t^2} + \nabla \phi + \frac{1}{\mu_0} (\delta B \times (\nabla \times B) + B \times (\nabla \times \delta B)) \left( \frac{\partial}{\partial t} \right) = 0, \quad (1a)$$

$$\delta \phi + \delta \xi \cdot \nabla p + \gamma \rho \nabla \cdot \delta \xi = 0, \quad (1b)$$

$$\delta B + \nabla \times (B \times \delta \xi) = 0, \quad (1c)$$

where, $\rho$, $p$, and $B$ are the density, kinetic pressure and magnetic field, respectively, at equilibrium. $\delta \xi$ is the Lagrangian displacement vector, $\delta \phi$ and $\delta B$ are the pressure and magnetic field perturbation, respectively, $\gamma$ is the ratio of specific heats (taken to be 5/3 in this work), and $\mu_0$ is the permeability of free space. In this study we employ cylindrical coordinates $(r, \varphi, z)$ and therefore $\delta \xi = (\delta \xi_r, \delta \xi_\varphi, \delta \xi_z)$. $\delta B = (\delta B_r, \delta B_\varphi, \delta B_z)$. In what follows an index, $i$, indicates quantities inside the flux tube ($r < r_a$) while variables indexed by, $e$, refer to the environment outside the flux tube ($r > r_a$). The model geometry is illustrated in Figure 1 when $B_{z,e} \propto 1/r$. For static equilibrium,

$$\nabla \cdot B = 0,$$  \hspace{1cm} (2a)

$$J = \frac{1}{\mu_0} \nabla \times B,$$  \hspace{1cm} (2b)

$$\nabla p = J \times B.$$  \hspace{1cm} (2c)

We assume that, $\rho$, $p$ and $B$ have only an $r$-dependence. We consider a magnetic field of the following form,

$$B = (0, B_\varphi(r), B_z(r)).$$  \hspace{1cm} (3)

Notice that in cylindrical coordinates, Equation (2a) is identically satisfied. Then, Equation (2b) expands to

$$\mu_0 J = \left( 0, - \frac{d B_\varphi}{dr}, \frac{d (r B_z)}{r dr} \right),$$  \hspace{1cm} (4)

and based on Equation (4), Equation (2c) becomes

$$\nabla p = \left( - \frac{B_\varphi}{\mu_0} \frac{d B_z}{dr} - \frac{B_z}{\mu_0 r} \frac{d (r B_\varphi)}{dr}, 0, 0 \right).$$  \hspace{1cm} (5)

Therefore, the pressure in the $\varphi$ and $z$ directions is constant and the magnetic field and the plasma pressure must satisfy the following pressure balance equation in the $r$ direction,

$$\frac{d}{dr} \left( p + \frac{B_\varphi^2 + B_z^2}{2 \mu_0} \right) + \frac{B_z^2}{\mu_0 r} = 0.$$  \hspace{1cm} (6)
For a magnetic flux tube of radius, \( r_a \), according to the Biot-Savart law (for \( \kappa = 1 \) in Equation (7)) a reasonable assumption for the form of the magnetic field is,

\[
B = \begin{cases} 
(0, S_i r, B_{zi}) & \text{for } r \leq r_a, \\
(0, r^2 + r S_i / r^\kappa, B_{zc}) & \text{for } r > r_a,
\end{cases}
\]

where, \( B_{zi}, B_{zc}, S_i \) and \( S_c \) are constants and \( \kappa \) is a perturbation parameter. The perturbation parameter has been inserted in Equation (7) in such a way so as to preserve dimensional consistency. The constant \( S_i \) can be determined by application of the Biot-Savart law and is therefore taken to be,

\[
S_i = \frac{\mu_0 I}{2 \pi r_a^{1+\kappa}},
\]

where \( I \) is the current. By substituting Equation (7) into Equation (6) we obtain:

\[
p(r) = \begin{cases} 
\frac{S_i^2}{\mu_0} (r_a^2 - r^2) + p_a & \text{for } r \leq r_a, \\
\frac{S_i^2}{\mu_0} (1 + 2 \kappa) \left( \frac{1}{r^{2\kappa}} - \frac{1}{r_a^{2\kappa}} \right) + p_a & \text{for } r > r_a,
\end{cases}
\]

where, \( p_a \) is the pressure at the boundary of the magnetic flux tube. The constant, \( S_c \), is equal to \( S_i \) however we choose to maintain the notational distinction so that we can separate the internal and external environments to the flux tube which helps validate our results with previous work (e.g. Erdélyi & Fedun 2007).

2.1. Governing Equations

The solution of the system of equations shown in Equation (1), in cylindrical coordinates can be found by Fourier decomposition of the perturbed components, namely the perturbed quantities are taken to be,

\[
\delta \xi, \delta \phi_T \propto e^{i(k_x \varphi + k_z z - \omega t)},
\]

where, \( \omega \) is the angular frequency, \( k_x \) is the azimuthal wavenumber for which only integer values are allowed and, \( k_z \), is the longitudinal wavenumber in the \( z \) direction. The Eulerian total pressure perturbation is, \( \delta p_T = \delta p + B \delta B / \mu_0 \), which is obtained by linearization of the total pressure: \( p_T = (p + \delta p) + (B + \delta B)^2 / (2 \mu_0) \) and \( p \) is the equilibrium kinetic pressure. Note that for the sausage mode, considered in this work, the azimuthal wavenumber is \( k_x = 0 \). Combining Equation (1) with Equation (10) we obtain the equation initially derived by Hain & Lust (1958) and later by Goedbloed (1971); Sakurai et al. (1991) to name but a few. This equation can be reformulated as two coupled first order differential equations,

\[
D \frac{d (r \delta \xi_T)}{dr} = C_1 (r \delta \xi_T) - r C_2 \delta \phi_T,
\]

\[
D \frac{d \delta \phi_T}{dr} = \frac{1}{r} C_3 (r \delta \xi_T) - C_4 \delta \phi_T,
\]

and the multiplicative factors are defined as:

\[
D = \rho (\omega^2 - \omega_A^2) C_4,
\]

\[
C_1 = \frac{2 B_{\phi}^2}{\mu_0 r} \left( \omega^2 B_{\phi} - \frac{k^2}{r} \right) C_4,
\]

\[
C_2 = \omega^4 - \left( \frac{k^2 + \frac{2}{r^2}}{r^2} \right) C_4,
\]

\[
C_3 = \rho D \left( \omega^2 - \omega_A^2 \right) + \frac{2 B_{\phi}^2}{\mu_0 r^2} \left( \frac{B_{\phi}}{r} \right)
\]

\[
+ 4 \omega^4 B_{\phi}^2 + \rho C_4 4 B_{\phi}^2 \omega_A^2,
\]

\[
C_4 = (v_s^2 + v_A^2) (\omega^2 - \omega_c^2),
\]

where,

\[
\omega_c^2 = \frac{v_s^2}{v_A^2 + v_s^2}, \quad \omega_A^2 = \frac{f_B^2}{\mu_0 \rho}, \quad f_B = \frac{k_{\phi} B_{\phi} + k_z B_z}{}\]

Here, \( v_s = \sqrt{\gamma p / \rho} \) is the sound speed, \( v_A = |B| / \sqrt{\mu_0 \rho} \) is the Alfvén speed, \( \omega_c \) is the cusp angular frequency and \( \omega_A \) is the Alfvén angular frequency. The coupled first order ODEs in Equation (11) can be combined in a single second order ODE for, \( \delta \phi_T \) or \( \delta \xi_T \). In this work we choose to use the latter approach, namely:

\[
\frac{d}{dr} \left[ \frac{D}{r C_2} \frac{d}{dr} (r \delta \xi_T) \right] + \frac{1}{D} \left( C_3 - \frac{C_4}{C_2} \right) \frac{d}{dr} \left( \frac{C_1}{r C_2} \right) \delta \xi_T = 0.
\]

Using flux coordinates and assuming \( k_{\phi} = 0 \), it can be shown that (Sakurai et al. 1991),

\[
\rho (\omega^2 - \omega_A^2) \delta \xi_\| = - \frac{k_z B_{\phi}}{|B|} \left( \delta \phi_T + \frac{2 B_{\phi}^2}{\mu_0 r} \delta \xi_T \right),
\]

\[
\rho (\omega^2 - \omega_c^2) \delta \xi_\perp = \frac{k_z B_z}{|B|} v_s^2 + v_A^2 \left( \delta \phi_T - \frac{2 B_{\phi}^2}{\mu_0 r} \delta \xi_T \right).
\]

Here \( \delta \xi_\| \) and \( \delta \xi_\perp \) are the Lagrangian displacement components parallel and perpendicular to the magnetic field lines respectively. The dominant component of the Lagrangian displacement vector (\( \delta \xi_\|, \delta \xi_\perp, \delta \xi_T \)) determines the character of the mode. For the Alfvén mode the \( \delta \xi_\| \) component is dominant, while for the slow and fast magnetoacoustic modes \( \delta \xi_\| \) and \( \delta \xi_T \) is dominant respectively (Goosens et al. 2011). Equation (14) suggests that in the presence of magnetic twist the slow and fast magnetoacoustic modes are coupled to the Alfvén mode even when \( k_{\phi} = 0 \), namely the slow and fast modes do not exist without the Alfvén mode and vice versa. This is because for the Alfvén mode to be decoupled from the slow and fast magnetoacoustic modes it is required that for \( \delta \xi_\| \neq 0, \delta \xi_T = 0 \) and \( \delta \xi_\perp = 0 \). However, it follows trivially from Equation (11) that, if \( \delta \xi_T = 0 \) then also \( \delta \phi_T = 0 \) and therefore from Equation (14) we have that \( \delta \xi_\| = 0 \). From this, it follows that the Alfvén mode cannot exist without the components corresponding to the slow and fast magnetoacoustic modes, hence the Alfvén mode is coupled with the slow and fast magnetoacoustic modes. Furthermore, from Equation (14) we can also see that for a solution, i.e. (\( \omega, k_z \)) pair, as \( \omega \) approaches \( \omega_A \) the \( \delta \xi_\| \) component is amplified that leads to the azimuthal component of the displacement to be accentuated.

Article number, page 3 of 11
3. Dispersion Equation

In this section we follow a standard procedure in deriving a dispersion equation, namely we solve Equation (13) inside and outside the flux tube and match the two solutions using the boundary conditions. The boundary conditions that must be satisfied are:

\[
\delta \xi_{ri}|_{r=r_a} = \delta \xi_{re}|_{r=r_a}, \quad (15a)
\]

\[
\delta \varphi_{Ti} - \frac{B_{gi}^2}{\mu_0 r} \delta \xi_{ri} \bigg|_{r=r_a} = \delta \varphi_{Te} - \frac{B_{ge}^2}{\mu_0 r} \delta \xi_{re} \bigg|_{r=r_a}, \quad (15b)
\]

where, Equation (15a) and Equation (15b) are continuity conditions for the Lagrangian displacement and total pressure across the tube boundary respectively.

3.1. Solution Inside the Flux Tube

The parameters in Equation (12) for the case inside the flux tube for the sausage mode become,

\[
D_i = \rho_i (\omega^2 - \omega_{Ai}^2), \quad (16a)
\]

\[
C_i = \frac{2S_i^2}{\mu_0} \rho_i n_i^2, \quad (16b)
\]

\[
C_3 = \rho_i (\omega^2 - \omega_{Ai}^2) + \frac{4S_i^2}{\mu_0 \rho_i} \left( \frac{S_i^2 r_i^2}{\mu_0 k_i} (\omega^2 - \omega_{Ai}^2) \right), \quad (16d)
\]

\[
n_i^2 = \frac{\omega^2}{(v_{si}^2 + v_{Ai}^2) (\omega^2 - \omega_{ci}^2)}, \quad (16c)
\]

where,

\[
\omega_{ci}^2 = \frac{v_{si}^2}{v_{si}^2 + v_{Ai}^2} \omega_{Ai}^2, \quad \omega_{Ai}^2 = k_z^2 \frac{B_{gi}^2}{\mu_0 \rho_i}
\]

The \( B_{gi} \) component is assumed small to avoid the kink instability, see for example (Gerrard et al. 2002; Török et al. 2004). This implies, \( B_{gi} \ll B_z \) and since \( B_{gi} \) is a function of \( r \) inside (and outside) the tube we require \( \text{sup}(B_{gi}) \ll B_z \Rightarrow S_{ra} \ll B_z \). This condition is satisfied in the solar atmosphere, so we can use the approximation: \( v_{Ai}^2 = (B_{gi}^2 + B_{gi}^2) / (\mu_0 \rho_i) \sim B_{gi}^2 / (\mu_0 \rho_i) \). Notice that according to Equation (9) the pressure depends on \( r \), however, in this work we assume that the sound speed is constant. This is because the term that depends on \( r \) in Equation (9) is assumed to be small when compared with \( p_a \) in solar atmospheric conditions. To see this, consider that \( \text{sup}(S_{ra}) = 0.2B_z \) and \( B_{gi} \sim (10^{-1} - 10^{-4}) \), \( T \sim (10^4 - 10^6) \) and the number density \( n \sim (10^{23} - 10^{16}) \) m\(^{-3}\). This means that \( p_a \sim (10^4 - 10^{-1}) N \cdot m^{-2} \) and the term that depends on the radius is of the order \( (S_{ra})^2 / \mu_0 \sim (10^{-2} - 10^{-4}) N \cdot m^{-2} \) and therefore the constant term \( p_a \) is \( (10^2 - 10^3) \) times larger when compared with the term that has an \( r \) dependence. Hence, to a good approximation, the pressure can be assumed to be constant. Note, that the density is discontinuous across the tube boundary and therefore we avoid the Alfvén and slow continua that lead to resonant absorption.

Substitution of the parameters in Equation (16) into Equation (13), leads to the following second order differential equation (see for example Erdélyi & Fedun 2007),

\[
R^2 \frac{d^2 \delta \xi_r}{dR^2} + \frac{d \delta \xi_r}{dR} - \left( 1 + \frac{k_{ri}^2}{k_z^2} R^2 + E R^4 \right) \delta \xi_r = 0, \quad (17)
\]

where,

\[
R = k_ar, \quad k_{ri}^2 = \left( k_z^2 v_{si}^2 - \omega^2 \right) \left( k_z^2 v_{Ai}^2 - \omega^2 \right),
\]

\[
E = \frac{4S_i^4 n_i^2}{\mu_0 D_i^2 k_z^2} (1 - \alpha^2)^2,
\]

\[
\alpha^2 = \frac{4S_i^2}{\mu_0 \rho_i (\alpha^2 - \omega_{Ai}^2)}.
\]

\[
v_{Ai}^2 = \frac{v_{Ai}^2}{v_{Ai}^2 + v_{si}^2}
\]

Here \( k_a = k_z (1 - \alpha^2)^{1/2} \) is the effective longitudinal wavenumber and \( v_{Ti} \) is the internal tube speed. Equation (17) was derived and solved before by Erdélyi & Fedun (2007). The solution is expressed in terms of Kummer functions (Abramowitz & Stegun 2012) as follows,

\[
\delta \xi_s(s) = A_{11} \frac{s^{1/2}}{E^{1/4}} e^{-s/2} M(a, b; s) + A_{12} \frac{s^{1/2}}{E^{1/4}} e^{-s/2} U(a, b; s), \quad (18)
\]

and the parameters, \( a \) and \( b \) and the variable \( s \) are defined as

\[ a = 1 + \frac{k_{ri}^2}{4k_z^2 E^{1/2}}, \]

\[ b = 2, \]

\[ s = R^2 E^{1/2} \]

\[ = k_a^2 E^{1/2}, \]

\[ A_{11} \quad \text{and} \quad A_{12} \quad \text{are \ constants. Furthermore,} \]

the total pressure perturbation, \( \delta \varphi_T \) is,

\[
\delta \varphi_T(s) = A_{11} \frac{k_a D_i}{n_i^2 - k_z^2} e^{-s/2} \left[ \frac{n_i + k_z}{k_z} s M(a, b; s) - 2M(a, b - 1; s) \right] + A_{12} \frac{k_a D_i}{n_i^2 - k_z^2} e^{-s/2} \left[ \frac{n_i + k_z}{k_z} s U(a, b; s) - 2(1 - a) U(a, b - 1; s) \right].
\]

Now, considering that solutions at the axis of the flux tube, namely at \( r = 0 \), must be finite, we take \( A_{12} = 0 \) and so

\[
\delta \xi_{ri}(s) = A_{11} \frac{s^{1/2}}{E^{1/4}} e^{-s/2} M(a, b; s), \quad (19a)
\]

\[
\delta \varphi_{Ti}(s) = A_{11} \frac{k_a D_i}{n_i^2 - k_z^2} e^{-s/2} \left[ \frac{n_i + k_z}{k_z} s M(a, b; s) - 2M(a, b - 1; s) \right]. \quad (19b)
\]

Note that the corresponding equation to Equation (19b) had a typographical error in Erdélyi & Fedun (2007) (see Equation (13) in that work).
3.2. Solution Outside the Flux Tube

The multiplicative factors in Equation (12) outside of the flux tube for the sausage mode, $k_z = 0$, become

\begin{align}
D_e &= \rho_e (\omega^2 - \omega^2_{Ac}), \\
C_1 &= \frac{2 r_\nu^2 (1+\kappa) S^2}{\mu_0 r^{2(1+\kappa)}}, \\
C_2 &= \frac{\omega^2}{k_z^2}, \\
C_3 &= \rho_e^2 (\omega^2 - \omega^2_{Ac})^2 \\
&+ \frac{4 r_\nu^2 (1+\kappa) S^2}{\mu_0 r^{2(1+\kappa)}} \left[ \frac{r_e^2 (1+\kappa) S^2}{\mu_0 r^{2n_z}} - \rho_e \omega^2_{Ac} - \nu \frac{1}{2} (\omega^2 - \omega^2_{Ac}) \right], \\
\nu_e &= \frac{\omega^4}{(v^2_{se} + v^2_{Ac})(\omega^2 - \omega^2_{Ac})},
\end{align}

where,

\[
\omega^2_{Ac} = \frac{v^2_{Ac}}{v^2_{se} + v^2_{Ac}}, \quad \omega^2_{Ac} = k_z^2 \frac{B^2_{se}}{\mu_0 \rho_e}.
\]

Equation (13) with Equation (20) for $\kappa = 1$ corresponds to $B_z \sim 1/r$, however, the resulting ODE is difficult to solve. By setting $\kappa = 0$ we obtain the case for constant twist outside the tube, which is also a zeroth-order approximation to the problem with $\kappa = 1$ (Bender & Orszag 1999). Note, that it is unconventional to use only the zeroth-order term in perturbative methods, and therefore, to establish the validity of the approximation we estimate the error by solving for $\kappa = 1$ numerically. The estimated error is quoted in the caption of the dispersion diagrams in this work and the process which we followed to obtain this is described in Appendix B. Substituting the parameters given in Equation (20) into Equation (13) we have

\[
r^2 \frac{d^2 \delta \xi_e}{dr^2} + \frac{d \delta \xi_e}{dr} \left( k_{re}^2 r^2 + \nu^2 (\kappa; r) \right) \delta \xi_e = 0,
\]

where, $k_{re}$ and $\nu$:

\[
k_{re}^2 = -(n_z^2 - k_e^2),
\]

\[
\nu^2 (\kappa; r) = 1 + 2 \frac{r_\nu^2 (1+\kappa) S^2}{\mu_0 D^2} \left[ \frac{r_e^2 (1+\kappa) S^2}{r^{2k_e^2}} + \mu_0 \rho_e \omega^2_{Ac} (n_z^2) (3 - 2\kappa) \right],
\]

\[
- k^2_e (1 - \kappa) - (n_z^2 + k_e^2) (1 + \kappa) \omega^2.
\]

Notice that $\nu^2 (0; r)$ is independent of $r$. Therefore, for $\kappa \to 0$, Equation (21) is transformed to either the Bessel equation for $k_{re}^2 < 0$ or the modified Bessel equation for $k_{re}^2 > 0$. It should be noted that $n_z^2 = k_e^2$, namely $k_{re}^2 = 0$, is prohibited since during the derivation of Equation (21) it was assumed that $n_z^2 \neq k_e^2$ to simplify the resulting equation. Therefore, the solution to Equation (21) for $\kappa \to 0$, and, assuming no energy propagation away from or towards the cylinder ($k_{re}^2 > 0$), is

\[
\delta \xi_e (r) = A_{e1} K_{\nu} (k_{re} r) + A_{e2} I_{\nu} (k_{re} r).
\]

On physical grounds we require the solution to be evanescent, i.e. $\delta \xi_e (r) \to 0$ as $r \to 0$, and therefore we must have $A_{e2} = 0$, namely

\[
\delta \xi_e (r) = A_{e1} K_{\nu} (k_{re} r),
\]

and, from Equation (11a), the total pressure perturbation $\delta p_{Te}$ is

\[
\delta p_{Te} = A_{e1} \left( \frac{\mu_0 (1 - \nu) D_e - 2 r_\nu^2 S^2 n_z^2}{\mu_0 r (k_e^2 - n_z^2)} K_{\nu} (k_{re} r) \right) - \frac{D_e}{k_{re}^2} K_{\nu - 1} (k_{re} r).
\]

Note that, for the case $k_{re}^2 > 0$ and $S_e \to 0$, namely zero twist outside the cylinder, $\nu^2 \to 1$, thus retrieving the solution for $\delta \xi_e$ by Edwin & Roberts (1983). The limiting cases for Equation (19a) and Equation (19b) have been verified to converge to the solutions with no twist inside the magnetic cylinder in Erdélyi & Fedun (2007) in Section 3.3.

3.3. Dispersion Relation and Limiting Cases

Application of the boundary conditions (see Equation (15a) and Equation (15b)) in combination to the solutions for $\delta \xi_e$ and $\delta p_{Te}$ inside the magnetic flux tube, Equation (19a) and Equation (19b) as well as the solutions in the environment of the flux tube, Equation (25) and Equation (26) respectively, leads to the following general dispersion equation, for the compressible case in presence of internal and external magnetic twist,

\[
\frac{r_e D_e}{k_{re}} \frac{K_{\nu - 1} (k_{re} r_a)}{K_{\nu} (k_{re} r_a)} = \frac{v^2_{se}}{v^2_{ac}} \left[ \frac{S^2}{r_\nu^2} (n_z + k_e^2) - \frac{S^2}{k_{re}^2} (n_z^2 + k_e^2) \right] \frac{(1 - \nu) D_e}{k_{re}^2} - 2 \frac{D_e}{k_{re}^2} M(a, b - 1; s) + \frac{2}{k_{re}^2} M(a, b; s).
\]

In order to validate Equation (27) we consider a number of limiting cases. First, the case where there is no external magnetic twist. In this case $S_e \to 0$ and from Equation (23) it follows trivially that, $\nu^2 (\kappa; r) = 1$. Therefore, Equation (27) for no external twist becomes:

\[
\frac{r_e D_e}{k_{re}} \frac{K_0 (k_{re} r_a)}{K_1 (k_{re} r_a)} = \frac{S^2}{r_\nu^2} (n_z + k_e^2) - 2 \frac{D_e}{k_{re}^2} M(a, b - 1; s) + \frac{2}{k_{re}^2} M(a, b; s).
\]

This equation is in agreement with the dispersion equation obtained by Erdélyi & Fedun (2007) and all the limiting cases therein also apply to Equation (27). However, there is one limiting case missing from the analysis in Erdélyi & Fedun (2007), namely for no twist inside and outside the tube with $k_{re}^2 < 0$, which in combination to $k_{ri}^2 > 0$ corresponds to body wave modes. We complete this analysis here. Starting with 13.3.1 and 13.3.2 in Abramowitz & Stegun (2012), in the limit as $S_i \to 0$ and $k_{ri}^2 > 0$ we have

\[
\lim_{S_i \to 0} (M(a, b - 1; s)) = I_1 (k_{ri} r),
\]

\[
\lim_{S_i \to 0} (M(a, b; s)) = \frac{2}{k_{ri}} I_1 (k_{ri} r),
\]

while for $k_{ri}^2 < 0$:

\[
\text{Article number, page 5 of 11}\]
while the solutions for the perturbed bands corresponding to  \( \delta \xi \)
\( k_d \)  
and  
\( \nuK \)
denoted with capitalized indices (see Appendix A). Therefore, Equation (28) in conjunction with the facts that \( J_0(s) = -J_1(s) \), \( I_0(s) = I_1(s) \) and \( K_0(s) = -K_1(s) \) (9.1.28 and 9.6.27 in Abramowitz & Stegun 2012) is, in the limit as \( S_i \rightarrow 0 \) equal to
\[
\lim_{S_i \rightarrow 0} (M(a, b - 1; s)) = J_0(k_r r), 
\]
\[
\lim_{S_i \rightarrow 0} (M(a, b; s)) = \frac{2}{K_{ir}} J_1(k_r r). 
\]
which are in agreement with Edwin & Roberts (1983) and describe wave mode for the case with no magnetic twist.

4. Dispersion Equation Solutions

To explore the behavior of the sausage mode Equation (27) was normalized and solved numerically for different solar atmospheric conditions, see Table 1. Normalized quantities are denoted with capitalized indices (see Appendix A). The solutions of the dispersion relation depend only on the relative ordering of the magnitudes of the characteristic velocities \( (v_{AE}, v_{AI}, v_{SE}, v_{SI}) \). The sign of \( k_{ir}^2 \) and \( k_{rr}^2 \) depends on this ordering and this in turn defines the three band types in the dispersion plot, i) bands that contain surface modes (for \( k_{ir}^2 > 0 \) and \( k_{rr}^2 > 0 \)), ii) bands that contain body modes (for \( k_{ir}^2 < 0 \) and \( k_{rr}^2 > 0 \)), and, iii) forbidden bands corresponding to \( k_{ir}^2 < 0 \). We make additional comments on the selection of the characteristic speeds in Appendix C. The non-dimensional dispersion equation is given in Appendix A while the solutions for the perturbed quantities in terms of \( \delta \xi \) and \( \phi_T \) are given in Appendix D.

4.1. High plasma-\( \beta \) regime

Based on the results by Vernazza et al. (1981) and the model for the plasma-\( \beta \) in the solar atmosphere introduced by Gary (2001) we anticipate that the results in this section are pertinent to conditions typically observed in the upper photosphere, lower chromosphere and mid-chromosphere. The solutions of the dispersion relation in Equation (27), in terms of the non-dimensional phase speed, \( v_F = v_{ph}/v_{AI} = \omega/k_r v_{AI} \) and the non-dimensional longitudinal wave-vector, \( K = k_z r \), for a warm dense tube (see Table 1) are shown in Figure 2. For this case the ordering of the characteristic speeds is as follows: \( v_{SE} > v_{SI} > v_{AE} > v_{AI} \). In this characteristic and, in the following, we over-plot two cases, i) \( B_{phi}/B_{zi} = 0.01 \) and, ii) \( B_{phi}/B_{zi} = 0.2 \), which correspond to (practically) no twist and small twist, respectively. The reason for using a small, but non-zero twist for the case corresponding to the dispersion relation with zero twist which we have shown to be equivalent to the result of Edwin & Roberts (1983), is that the limits of the Kummer functions in Equation (29) and Equation (30) require an increasing number of terms as \( a_i \rightarrow 0 \) and their calculation becomes inefficient by direct summation. However, \( B_{phi}/B_{zi} = 0.01 \) is a good approximation to the case with zero azimuthal magnetic field component. Note that in the following we take the twist, namely \( B_{phi}(r) \), to be continuous across the flux tube and thus set, \( S_i = S_e \). The behavior of the fast sausage body waves (FSBW) is very similar for both the case with and without twist, and in extension it is very similar to the case with only internal twist studied by Erdélyi & Fedun (2007). It is worth noting that when internal and external twist is present, the different radial harmonics of the FSBW modes have two solutions, one dispersive and one approximately non-dispersive see Figure 2. It is, however, unclear if the non-dispersive solution remains valid until the next radial harmonic. Nevertheless, it is clear that, in the neighborhood of the \( v_{SE} \) singularity we obtain two solutions with comparable phase speeds (\( v_F \)) which opens the possibility for beat phenomena and thus widens the possibility of detection of these waves since the beat frequency will be smaller than both waves that produce it. This behavior is not present when we consider twist only inside the flux tube. Otherwise, the overall behavior of the solutions is virtually identical to Erdélyi & Fedun (2007).
Fig. 3. Solutions of the dispersion Equation (27) for a cool evacuated tube embedded in a dense environment ($\beta_s \ll 1, \beta_t \geq 1$) with speed ordering $v_{SE} > v_{AI} > v_{AR} > v_{SI}$. The top figure corresponds to no external twist for $r > r_e$, namely $S_e = 0$, while in the lower plot there is twist outside as well as inside the flux tube. Note that in both figures the solutions for $B_{zi}/B_s = [0.01, 0.05, 0.1, 0.15, 0.175, 0.2]$ have been over-plotted to conserve space and illustrate the effect of increasing the magnetic twist. The axes inside the figures match the progression of twist for the specific regions, for instance, in the top plot the axis with the arrow to the left indicates that the first FSBW from the right corresponds to magnetic twist of 0.01 the second to 0.05 etc. Note that the vertical axis, for $B_{zi}/B_s = 0.01$ has no non-dispersive FSSW (horizontal solutions marked in red) which is indicated by the empty parenthesis near the value 0.01. The mean RMSE is 0.021.

Fig. 4. Plots of density perturbations superimposed on the background equilibrium density plots for the fast body and surface modes shown in Equation (3). The gray lines represent velocity perturbation streamlines on the $xy$-plane. Notice that for visualization purposes the streamlines contain no information on the magnitude of the perturbation, only direction information is conveyed. In the density plots red and blue correspond to high and low density respectively. The slices are snapshots at $t = 0$ at different positions for the wavelength $\lambda$ of the oscillation. Note that this does not imply that the wavelength of the two oscillations is the same, rather, it is a fraction of the corresponding wavelength. (Left) Fast body mode for with magnetic twist for $K = 0.3624$ and $v_F = 1.071$. (Right) Fast surface mode with magnetic twist for $K = 3.494$ and $v_F = 0.9058$. Notice that in both cases the azimuthal component of the velocity perturbation at $0/8\lambda, 4/8\lambda$ and $8/8\lambda$ is non-zero.

interesting since in some interval of $K$ there exist 3 simultaneous solutions while outside of this interval exists only one. This means that within that interval, for a broadband excitation, the power of the driver will be distributed to more than one solution thus reducing the individual power spectrum signatures of the individual waves. In essence this will result in a interval of solutions that are much more difficult to detect. Another interesting point in respect to this s-like set of solutions is that it seems that a point may exist, for a certain value of $B_{zi}/B_s$ and a single $K$ that there would be a continuum as the $s$-shape becomes vertical (see Figure 3). However, the existence or physical significance of this point is speculative since it does not appear to exist for small twist, namely the regime for which our approximation is valid. In Figure 4 we illustrate a FSBW (left panel) and a SSBW (right panel). In contrast to the kink mode in magnetic flux tubes with weak twist that exhibit a polarization (Terradas & Goossens 2012), the sausage mode appears to be the a superposition of an Alfvenic wave and a sausage wave leading by $\pi/2$.

The last plasma regime with high plasma-$\beta$ considered in this work has the following characteristic speed ordering: $v_{SE} > v_{SI} > v_{AI} > v_{AE}$. In Figure 5 we plot the solutions to Equation (27) for this case. The most notable feature, which seems to be consistent for alternative parameter sets corresponding to photospheric conditions, is that the magnetic twist appears to have only a small effect on...
we consider an intense warm flux tube for speed ordering $v_{SE} > v_{SI} > v_{AI} > v_{AE}$. The mean RMSE is 0.0547.

Fig. 5. Solutions of the dispersion Equation (27) for a weak cool tube embedded in a dense environment ($\beta_i > 1, \beta_e \gg 1$) with speed ordering $v_{SE} > v_{SI} > v_{AI} > v_{AE}$. The mean RMSE is 0.0291.

Fig. 6. Solutions of the dispersion Equation (27) for an intense warm tube embedded in a rarefied environment ($\beta_i \ll 1, \beta_e \ll 1$) with the following speed ordering, $v_{AE} > v_{SI} > v_{AI} > v_{SE}$. The deviation of the normalized phase speed was on the order of 0.5% or less for magnetic twist up to $B_{\phi i}/B_{zi} = 0.2$.

4.2. Low plasma-\(\beta\) regime

In consultation with the results presented by Vernazza et al. (1981) and Gary (2001), we expect the results presented in this section to be most relevant to conditions that are typical of the upper chromosphere the transition region and corona. The remaining two cases that we consider in this work are for low plasma-\(\beta\) conditions (see Table 1).

In Figure 6 we consider an intense warm flux tube for which the characteristic speeds ordering is the following: $v_{AE} > v_{SI} > v_{AI} > v_{SE}$. This case was also considered by Erdélyi & Fedun (2007) under the assumption that there is only internal magnetic twist and zero twist in the environment surrounding the flux tube. In that work the influence of twist was under a percent, however, when the external twist is also considered interesting behavior emerges. In this case, when there is zero twist, the first SSBW changes character to a slow sausage surface wave (SSSW) crossing $v_{AI}$ at approximately $K = 0.25$. When a small twist is introduced the first radial harmonic of the SSSW modes now becomes bounded by $v_{AI}$ and a SSSW mode appears. Also, a non-dispersive solution with a character similar to a surface wave emerges that closely follows $v_{AI}$. We have named this solution as surface-Alfvén wave (SAW) in Figure 6 and we have expanded the plot to make it visible since it is extremely close to the internal Alfvén speed. Interestingly the higher radial harmonics of the SSSW appear to be minimally affected when the magnetic twist is increased. Also, the correction to the phase velocity for the FSBW with magnetic twist appears to be small compared with the case of no magnetic twist. For the first radial harmonic this correction is of the order of 0.4% while the correction is less than 0.1% for higher radial harmonics. However, this does not mean that the FSBW for the case with magnetic twist is identical to the case without twist. This is because the azimuthal component of the velocity perturbation in the former case is non-zero altering the character of these waves significantly as compared with its counterpart in the case without magnetic twist.

Lastly an intense cool tube is considered, i.e. $v_{AE} > v_{AI} > v_{SE} > v_{SI}$, which corresponds to conditions in the solar corona. The solutions to the dispersion equation (i.e. Equation (27)) are shown in Figure 7. In this case, magnetic twist has more pronounced effect on the FSBWs, while the SSSW are virtually unaffected. In the long wavelength limit, $K \ll 1$, the FSBWs become non-dispersive while for short wavelength limit, $K \gg 1$, the solutions are identical to the case of a straight magnetic flux tube with vertical magnetic field only. It is important to note that, although the effect of magnetic twist appears to be subtle in this case, it has a significant difference compared with the case with no magnetic twist, e.g. Edwin & Roberts (1983), as well as the case considering only internal magnetic twist, e.g. Erdélyi & Fedun (2007). In both of these cases the sausage...
mode becomes leaky as $K \to 0$. This however, is not the case when both internal and external twist are considered. Instead, as the magnetic twist increases so does the cutoff of the trapped fast sausage waves toward longer wavelengths. For example, for the particular characteristic speeds ordering considered in Figure 7, the first FSBW ceases to have a cutoff wavelength when $B_{\varphi i}/B_{\varphi i} > 0.05$, approximately. Therefore, the FSBW for a twisted magnetic cylinder above a certain threshold remains trapped for all wavelengths. A consequence of this is that FSBWs remain in the Alfvén continuum and therefore may be resonantly damped, see for example Sakurai et al. (1991). This means that the sausage mode cannot be ruled out as a source of energy to the corona.

5. Discussion

Although the model we present in this work for a magnetic flux tube with internal and external twist is relatively advanced in comparison to recent theoretical models, it contains a number of simplifications and therefore we would be remiss not to discuss the potential caveats when used to interpret observations. Observations suggest that the cross-section of magnetic flux tubes is not circular. Although there are no theoretical studies of magnetic flux tubes with completely irregular cross-section, some steps towards this direction have been taken by considering flux tubes with elliptical cross-section, see for example Ruderman (2003) and Erdélyi & Morton (2009). The results for the sausage mode presented in Erdélyi & Morton (2009) show that in comparison with the model of Edwin & Roberts (1983) (circular cross-section) the ellipticity of the cross-section tends to increase the phase speed of the sausage mode for photospheric conditions by approximately 5% in the short wavelength limit, and, is negligible in the long wavelength limit. Conversely, in coronal conditions for increasing ellipticity the phase speed increase is more pronounced for a wide range of wavelengths and is shown to be as much as 20% higher of the predicted phase speed by the model with circular cross-section. This effect is quite important since, for sufficiently large ellipticity, it could counteract the effect that magnetic twist has on the cutoff frequency for the fast sausage body modes seen in Figure 7. Namely, as can be seen in Figure 7, the fast sausage mode remains trapped in the long wavelength limit, however, should the phase speed be increased, then a cutoff frequency for the fast sausage body modes may be reinstated.

Furthermore, although we have studied propagating waves in this work, the study of standing modes for $k_\varphi = 0$ is trivially extended. Namely, if the magnetic flux tube is line-tied on both footpoints the longitudinal wavevector will be quantized according to $k_\varphi = n\pi/L$, where $n$ is an integer and $L$ is the length of the magnetic flux tube. If the flux tube is assumed to be line tied on one end and open on the other, then no quantization takes place and there can be propagating and standing waves for all $k_\varphi$. Here it should be mentioned that the effect of the magnetic flux tube curvature is of the order of $(r_\varphi/L)^2$ and therefore has a small effect on the eigenfrequencies of magnetic flux tubes in the solar atmosphere (van Doorsselaere et al. 2004, 2009).

Other effects that can alter the eigenfrequencies predicted using the model in this work are, density stratification, flux tube expansion and resonance phenomena due to neighboring magnetic flux tubes, see Ruderman & Erdélyi (2009) for a more in depth discussion. Of course, more complicated magnetic field topologies can have other unforeseen effects. This can be seen in magneto-convection simulations, e.g. Wedemeyer-Böhm et al. (2012), Shelyag et al. (2013), Trampedach et al. (2014) as well as in simulations with predefined background magnetic fields, see Bogdan et al. (2003), Vigeesh et al. (2012), Fedun et al. (2011). However, the interpretation of the results from such simulations is a major challenge which is only increased by considering that the initial conditions, which are mostly unknown, play a very important role in their subsequent evolution.

6. Conclusions

In the presence of weak twist the sausage mode has mixed properties since it is unavoidably coupled to the axisymmetric Alfvén wave. This apparent from the solutions, see for example Appendix D where the azimuthal velocity perturbation component is nonzero and is also supported by the results presented in Section 2.1. The implications of this on the character of surface and body waves are seen clearly in Figure 4, where the relative magnitude of the radial and azimuthal components of the velocity perturbation alternate periodically and waves tend to exhibit Alfvénic character the closer their phase velocity is to one of the Alfvén speeds. The reason for this behaviour has been explained in Section 2.1.

Observations of Alfvén waves rely on the apparent absence of intensity (i.e. density) perturbations in conjunction with torsional motion observed by alternating Doppler shifts, see for example Jess et al. (2009). The results of this work suggest that there exists at least one more alternative interpretation for waves with the aforementioned characteristics. Namely, the observed waves by Jess et al. (2009) could potentially be surface sausage waves (see right panel of Figure 4), since the localized character of the density perturbation also implies localized intensity perturbations that can be well below the instrument resolution. Furthermore, given the presence of torsional motion (see right panel of Figure 4) the sausage mode will have a Doppler signature similar to that of an Alfvén wave. The Doppler signature in combination with the fact that surface waves can have a phase velocity very close to the Alfvén speed (see SAW in Figure 6) suggests that Jess et al. (2009) potentially observed a sausage mode in the presence of magnetic twist. This line of reasoning is further supported by the evidence in Wedemeyer-Böhm et al. (2012) and Morton et al. (2013), where the authors show that vortical motions are ubiquitous in the photosphere. However, the excitation of the decoupled Alfvén wave requires vortical motion that is divergence free, see for example Ruderman et al. (1997), while the vortical motions observed in Morton et al. (2013) are not free of divergence. In our view these vortical motions could be a natural mechanism for the excitation of the axisymmetric modes studied in this work.

In this work we considered the effect of internal and external magnetic twist on a straight flux tube for the sausage mode. It was shown that magnetic twist naturally couples axisymmetric Alfvén waves with sausage waves. Some of the main results of this coupling are:

- Sausage waves can exhibit Doppler signatures similar to these expected to be observed for Alfvén waves.

Article number, page 9 of 11
– The phase difference between the radial and torsional velocity perturbations are $\pi/2$, which means that both effects can be simultaneously observed.
– Excitation of these modes can be accomplished with a larger variety of drivers compared to the pure sausage and axisymmetric Alfvén waves. Therefore, we speculate that these waves should be more likely to be observed compared with their decoupled counterparts.
– For coronal conditions the fast sausage body waves remain trapped for all wavelengths when the magnetic twist strength surpasses a certain threshold. This appears to be characteristic of magnetic twist and could potentially be used to identify the strength of the magnetic twist.

These findings suggest that axisymmetric modes with magnetic twist can be easily mistaken for pure Alfvén waves.

Appendix A: Dimensionless Dispersion Equation

For completeness we give here the dimensionless version of the dispersion equation (Equation 27). The following equation is now a function of $v_F$ and $K$, instead of $\omega$ and $k_z$. One of the benefits of solving Equation (A.1) instead of Equation (27) directly is that the former is, usually, numerically more stable. Another benefit is that the study of different plasma conditions is made simpler since it is straightforward to alter the ordering of the characteristic speeds ($v_{si}$, $v_{AI}$, etc).

$$\rho_i K(v_p^2 - v_{AE}^2) K^{-1}(K_i E K)$$

$$= \left[ \frac{v_p^2}{k_I^2}(1 + N_I^2) - \frac{\rho_i v_p^2}{k_I^2}(1 + N_E^2) \right]$$

$$+ \rho_i (1 - \nu)(v_p^2 - v_{AE}^2) F_2^{2} \frac{(v_p^2 - 1) M(a, b; 1 - s)}{M(a, b; s)}$$

$$\text{(A.1)}$$

where,

$$a = 1 + \frac{k_I^2 k_{I_E}^2}{v_{AE}^2} N_I (v_p^2 - 1), \quad b = 2, \quad s = \frac{v_p^2 - v_{AE}^2}{v_p^2 - 1}$$

$$v_{ph} = \frac{\omega}{k_z}, \quad v_F = \frac{v_{ph}}{v_{AI}}, \quad v_{SI} = \frac{v_{SI}}{v_{AI}}, \quad v_{SE} = \frac{v_{SE}}{v_{AI}}, \quad v_{AE} = \frac{v_{AE}}{v_{AI}}$$

$$v_{AI} = 1, \quad v_{AE} = \frac{v_{AE}}{v_{AI}}, \quad n_I^2 = k_z^2 N_I, \quad n_e^2 = k_z^2 N_E$$

$$k_T^2 = k_t^2 k_{I_E}^2, \quad k_{se}^2 = k_{se}^2 k_{E}^2$$

$$v_{TI} = \frac{v_{TI}}{v_{AI}}, \quad v_{TE} = \frac{v_{TE}}{v_{AI}}, \quad \mathcal{K} = k_z r_a, \quad v_{AI} = \frac{v_{AI}}{v_{AI}}$$

$$v_{AE} = \frac{v_{AE}}{v_{AI}},$$

and

$$N_I^2 = \frac{v_p^2}{v_p^2 + v_{AE}^2 (v_p^2 - 1)}, \quad N_E^2 = \frac{v_p^2}{v_p^2 v_{AE} + v_{SE} (v_p^2 - 1)}$$

$$k_I^2 = \frac{v_{SI}^2 - v_{AE}^2}{(1 + v_{SI}) (1 - v_p^2)}, \quad k_{IE}^2 = \frac{(v_{SI}^2 - v_{AE}^2) (v_{SA}^2 - v_{AE}^2)}{(v_{AE}^2 + v_{SE}^2) (v_{AE}^2 - v_p^2)}$$

$$v_{TI}^2 = \frac{v_{SI}^2 v_{AI}}{v_{AI}^2 + v_{SI}^2}, \quad v_{TE} = \frac{v_{SI}^2 v_{SE}}{v_{AE}^2 + v_{SE}^2}, \quad v_{AE}^2 = \frac{v_{SE}^2}{v_{AE}^2 + v_{SE}^2}.$$
Now notice that the above matrix is rank 4 which means that the dimension of the null-space is 2, with basis vectors: 
\[ y_1 = (1, 0, 0, 0, 1, 0), \text{and } y_2 = (0, 1, 0, 0, 0, 1). \] This means in practice that for a given set of parameters resulting in a specific speed ordering \( \beta_1 \) and \( \beta_2 \) are uniquely defined but there is a 2 dimensional subspace involving \( B_{z_1}^*, B_{z_2}^*, n_1^*, n_2^* \), that is, all linear combinations of \( y_1 \) and \( y_2 \). Also notice that the sound speeds, \( v_1^* \) and \( v_2^* \) depend only on the internal and external temperature, \( T_e \) and \( T_s \). Additionally the null-space of the matrix (see the basis vectors \( y_1 \) and \( y_2 \)) suggests that the densities, \( n_1^* \) and \( n_2^* \), are secondary variables to the magnetic field strength, \( B_{z_1}^* \) and \( B_{z_2}^* \).

\section*{Appendix D: Perturbed quantities in terms of \( \delta \xi_r \) and \( \delta p_T \)}

Given, \( \delta \xi_r \) and \( \delta p_T \) in Equation (19a), Equation (19b) or Equation (25), Equation (26) the remaining perturbed quantities for the sausage mode (\( k_\varphi = 0 \)) are (Erdélyi & Fedun 2010)

\[ \delta \xi_r(s) = \frac{1}{A_1} \left[ \frac{k_\varphi}{n_1^2 - n_2^2} e^{-s/2} M(a, b; s) \right], \]

\[ \delta p_T(s) = \frac{1}{A_1} \left[ \frac{k_\varphi}{n_1^2 - n_2^2} e^{-s/2} \left[ \frac{n_1 + k_\varphi}{k_\varphi} sM(a, b; s) \right] - 2M(a, b; s) \right], \]

\[ \delta \xi_r(r) = A_2 K_\nu(k_\varphi r), \]

\[ \delta p_T = A_2 \left[ \frac{\mu_0 (1 - \nu) D_e}{\mu_0 r (k_\varphi^2 - n_1^2)} K_\nu(k_\varphi r) \right] - \frac{D_e}{k_\varphi k_\nu} K_{\nu-1}(k_\varphi r), \]

\[ \delta \xi_r = \frac{i k_\varphi}{\rho \omega^2 - \omega_A^2} B_z B_0 \left[ \frac{n_1^2 + n_2^2}{2} \right] \left[ \frac{2B_z^2}{\mu_0 r^2} \delta \xi_r - \delta p_T \right] \]

\[ \delta \xi_r = \frac{i k_\varphi}{\rho \omega^2 - \omega_A^2} \left[ \omega^2 - n_1^2 \omega_A^2 \delta p_T + \frac{2B_z^2}{\mu_0 r^2} n_1^2 \delta \xi_r \right] - \frac{2B_z^2}{\mu_0 r^2} \delta \xi_r, \]

\[ \delta B_r = i k_\varphi B_z \delta \xi_r, \]

\[ \delta B_\varphi = \frac{k_\varphi B_z}{D} \left[ \delta p_T + \frac{2B_z^2}{\mu_0 r^2} \delta \xi_r \right] - \frac{d}{dr} (B_\varphi \delta \xi_r), \]

\[ \delta B_z = \frac{1}{r} \frac{d}{dr} (r B_\varphi \delta \xi_r). \]
