M-theory on eight-manifolds revisited: 
\( \mathcal{N} = 1 \) supersymmetry and generalized \( Spin(7) \) structures

Abstract: The requirement of \( \mathcal{N} = 1 \) supersymmetry for M-theory backgrounds of the form of a warped product \( \mathcal{M} \times_w X \), where \( X \) is an eight-manifold and \( \mathcal{M} \) is three-dimensional Minkowski or AdS space, implies the existence of a nowhere-vanishing Majorana spinor \( \xi \) on \( X \). \( \xi \) lifts to a nowhere-vanishing spinor on the auxiliary nine-manifold \( Y := X \times S^1 \), where \( S^1 \) is a circle of constant radius, implying the reduction of the structure group of \( Y \) to \( Spin(7) \). In general, however, there is no reduction of the structure group of \( X \) itself. This situation can be described in the language of generalized \( Spin(7) \) structures, defined in terms of certain spinors of \( Spin(TY \oplus T^*Y) \). We express the condition for \( \mathcal{N} = 1 \) supersymmetry in terms of differential equations for these spinors. In an equivalent formulation, working locally in the vicinity of any point in \( X \) in terms of a ‘preferred’ \( Spin(7) \) structure, we show that the requirement of \( \mathcal{N} = 1 \) supersymmetry amounts to solving for the intrinsic torsion and all irreducible flux components, except for the one lying in the 27 of \( Spin(7) \), in terms of the warp factor and a one-form \( L \) on \( X \) (not necessarily nowhere-vanishing) constructed as a \( \xi \) bilinear; in addition, \( L \) is constrained to satisfy a pair of differential equations. The formalism based on the group \( Spin(7) \) is the most suitable language in which to describe supersymmetric compactifications on eight-manifolds of \( Spin(7) \) structure, and/or small-flux perturbations around supersymmetric compactifications on manifolds of \( Spin(7) \) holonomy.

Keywords: .
1. Introduction

It has been observed (starting with [1]), in connection to supergravity compactifications, that the concept of $G$-structures is a natural generalization of special-holonomy to the case where fluxes are present. Supersymmetry implies the existence of a nowhere-vanishing spinor on the internal manifold $X$, thereby reducing the structure group of $X$ to $G$. In the presence of fluxes, $X$ is no longer special-holonomy and the spinor is no longer covariantly constant: its failure to be such is parametrized by the (flux-dependent) intrinsic torsion of the Levi-Civita connection associated with the $G$-invariant metric on $X$. Moreover, the intrinsic torsion can be decomposed in irreducible $G$-modules, giving a characterization of $X$.

More recently, it was realized [2, 3, 4, 5, 6, 7] that generic spinor Ansätze for the supersymmetry parameter naturally lead to the concept of generalized $G$-structures [8]. Roughly-speaking, generalized $G$-structures arise as follows: typically there will be two nowhere-vanishing spinors $\epsilon^\pm$ in the Ansatz for the supersymmetry parameter, each one inducing a reduction of the structure group to a subgroup $G^\pm$. Noting, in addition, that there is an isomorphism between bi-spinors on $X$ and spinors of $TX \oplus T^*X$, we conclude that $\rho := \epsilon^+ \otimes \epsilon^-$ (which can also be thought of –by Fierzing– as a sum of forms on $X$) induces a reduction of the structure group of $TX \oplus T^*X$ to $G^+_+ \times G^-_\subset \text{Spin}(TX \oplus T^*X)$.

In addition to the reduction of the structure group of $TX \oplus T^*X$, supersymmetry implies that $\rho$ should satisfy certain differential equations. For type II supergravities and for $X$ a six- or seven-dimensional manifold, these equations have been identified, in the case where the Ramond-Ramond fields are zero, with certain integrability conditions for the generalized structures [3]. Recently it has been possible to give a satisfactory mathematical description of the RR forms [3] by a generalization of the Hitchin functional [9] in which the RR forms appear as constraints. The role of the Hitchin functional in various topological theories is explored in [10, 11, 12, 13, 14].

Although a great deal is known about the connection of supersymmetry to generalized structures in six and seven dimensions, the case of eight-dimensional manifolds remains rather obscure (see however [15, 16]). In the present paper we wish to remedy the situation by examining the conditions for the most general $N = 1$ three-dimensional AdS or Minkowski vacua in M-theory. An immediate consequence of supersymmetry is that associated with the eight-dimensional internal manifold $X$ there is a nine-manifold $Y := X \times S^1$, such that $Y$ supports a generalized $\text{Spin}(7)$ structure on the sum of its tangent and cotangent bundles. The structure is given in terms of certain bispinors (spinors of $\text{Spin}(9, 9)$) which are constrained to satisfy certain differential equations.

In a more conventional (equivalent) formulation, we show that $N = 1$ supersymmetry implies the existence of a nowhere-vanishing Majorana spinor on $X$. This lifts to a nowhere-vanishing spinor on $Y = X \times S^1$ and hence implies the reduction of the structure group of $Y$ to $\text{Spin}(7)$. Note that, in general, $X$ does not support nowhere-vanishing Majorana-Weyl spinors and the structure group of $X$ itself is not, in general, reduced. However, working locally in an open set of $X$, one can still decompose all fields in terms of irreducible $\text{Spin}(7)$-modules. We are then able to solve for the intrinsic torsion and all irreducible flux components, except for the one lying in the 27 of $\text{Spin}(7)$ which cannot be determined by the supersymmetry equations, in terms of the warp factor and a certain one-form $L$ on $X$ (constructed as a $\xi$ bilinear). $L$ is not necessarily nowhere-vanishing, unless the structure group is
further reduced to $G_2$. In addition, $L$ is constrained to satisfy a pair of differential equations.

The case examined here is an alternative formulation to the works of [17, 18], which assume the existence of at least one nowhere-vanishing Majorana-Weyl spinor, as well as of [19] (see also [20]). The authors of reference [19] perform their analysis by decomposing the flux and the intrinsic torsion of the internal manifold in terms of irreducible $G_2$ representations. These decompositions are valid only outside the zero locus of both Majorana-Weyl spinors $\xi^\pm$, where $\xi = \xi^+ \oplus \xi^-$, and they break down at the points where either of $\xi^\pm$ vanishes. The analysis of [19] is valid globally only if there is a further reduction of the structure group of $X$ to $G_2$. Note, however, that in open sets where neither of $\xi^\pm$ vanishes, the analysis of [19] is perfectly sufficient to determine the most general local form of the geometry. In such opens sets, our formulæ in section 3.1 below should reduce to the corresponding formulæ given in [19], to the extent they overlap (some of the flux components were not given explicitly in [19]).

There are certain cases in which it is advantageous to work with a $\text{Spin}(7)$ rather than with a $G_2$ structure. Clearly this is true if one wishes to consider supersymmetric M-theory compactifications on eight-manifolds with a global $\text{Spin}(7)$ structure. A (very) special case thereof is compactifications on eight-manifolds with $\text{Spin}(7)$ holonomy. Also, even in the generic case of compactifications on eight-manifolds $X$ where there is no reduction of the structure group of $X$ to $\text{Spin}(7)$, it is still advantageous to work with a $\text{Spin}(7)$ structure if one wishes to describe the local geometry in the vicinity of a point where either of $\xi^\pm$ vanishes. Put in another way: let $P$ be an arbitrary point in $X$. There is always an open set $U_P \subset X$ such that $P \in U_P$ and at least one of $\xi^\pm$ is nowhere-vanishing in $U_P$. I.e. for any point $P$, there is always an open patch $U_P$ containing $P$, such that the decomposition in $\text{Spin}(7)$ modules is valid in $U_P$. The same is not true for $G_2$, as can be seen by taking $P$ to be a point where one of $\xi^\pm$ vanishes.

The plan of this paper is as follows: section 2 includes some general background on $G$-structures and, more particularly, $\text{Spin}(7)$-structures. In section 3 we perform the supersymmetry analysis in terms of (ordinary) $\text{Spin}(7)$-structures on $X$. As an explicit example we have also included a small-flux perturbation around the special-holonomy solution involving the non-compact $\text{Spin}(7)$-manifold of [21, 22]. Section 4 includes the supersymmetry analysis in terms of generalized $\text{Spin}(7)$ structures. The final section includes some discussion of future directions. To improve the presentation of the paper, almost all of the technical details of the supersymmetry analysis have been relegated to the appendices.

2. G-structures and intrinsic torsion

In this section we give a brief review of G-structures and intrinsic torsion with emphasis on the points relevant to our case.

Quite generally, the requirement of supersymmetry for backgrounds of the form $\mathcal{M} \times_X Y$, where $\mathcal{M}$ is maximally-symmetric, implies the existence of a nowhere-vanishing spinor $\xi$ satisfying a Killing equation

$$\nabla_m \xi = G_m \xi ,$$

(2.1)
where $\nabla_m$ is the Levi-Civita connection and $G_m$ is a vector field on $X$ taking values in the Clifford algebra $\text{Cliff}(d)$, $d := \dim_{\mathbb{R}}(X)$. The exact expression depending on the supergravity under consideration, $G_m$ is determined by the fluxes (i.e. antisymmetric tensor fields) on $X$ and is generally nonzero. If $G_m$ vanishes identically, $X$ is a special-holonomy manifold.

Typically, the existence of $\xi$ implies the reduction of the structure group to a subgroup $G \subset \text{Spin}(d)$ and the manifold $X$ admits a $G$-structure. The latter is characterized by the intrinsic torsion, which is a measure of the failure of $\xi$ to be covariantly constant with respect to the connection associated with the metric induced by the $G$-structure. From what has been just said, it is clear that the intrinsic torsion could be read off of $G_m$ in equation (2.1) above. Hence the result that the intrinsic torsion can be expressed in terms of the fluxes. Schematically:

$$\text{flux} \rightarrow G_m \rightarrow \text{intrinsic torsion}.$$  

Typically, the Killing spinor $\xi$ gives rise to certain $G$-invariant forms $(\Phi)$, constructed out of $\xi$ as spinor bilinears. It is an important result that the intrinsic torsion $(\omega)$ can also be read off of the exterior derivatives of these forms:

$$\nabla \xi \leftrightarrow \omega \leftrightarrow d\Phi.$$  

Having a dictionary between these two alternative descriptions is very useful in practice, as it allows us to express the supersymmetry equation (2.1) in purely algebraic form. We will see how this works explicitly in section 3.1.

The intrinsic torsion can be decomposed in terms of irreducible $G$-modules: $\omega \in \Lambda^1 \otimes \mathfrak{g}^\perp$, where $\mathfrak{g}^\perp$ is the complement of $\mathfrak{g} := \text{Lie}(G)$ inside $spin(d)$. Special classes of manifolds arise when some of these modules vanish; for example when all the modules vanish the manifold is special-holonomy. The construction/classification of manifolds according to their intrinsic torsion is a difficult problem which still remains largely open. There is of course great interest from the physics point-of-view because of the connection to flux compactifications. In some cases it is not known if examples of manifolds exist in all classes of possible combinations of nonzero modules.

### 2.1 Spin(7) structure

Let us now see how the general discussion of $G$-structures applies to the case where $X$ is an eight-manifold. The main result explained here is that the existence of a nowhere-vanishing Majorana spinor on $X$, $\xi = \xi^+ \oplus \xi^-$ where $\xi^+$ ( $\xi^-$) is of positive (negative) chirality, induces the reduction of the structure group of the associated nine-manifold $Y := X \times S^1$, where $S^1$ is a circle of constant radius, to $\text{Spin}(7)$.

A $\text{Spin}(7)$ structure on $X$ is a principal sub-bundle of the frame bundle over $X$, with fiber the subgroup $\text{Spin}(7)$ of $GL(8, \mathbb{R})$. We can give alternative description of the $\text{Spin}(7)$ structure as follows [23]: let $x^1, \ldots, x^8$ be the coordinates of $\mathbb{R}^8$. The self-dual four-form

$$\Phi_0^+ := e^{1234} + e^{1256} + e^{1278} + e^{1357} - e^{1368} - e^{1458} - e^{1467} - e^{2358} - e^{2367} - e^{2457} + e^{2468} + e^{3456} + e^{3478} + e^{5678},$$  

(2.4)
where $e^{ijkl}$ denotes $dx^i \wedge dx^j \wedge dx^k \wedge dx^l$, is fixed by $Spin(7) \subset GL(8, \mathbb{R})$. At each point $p \in X$ let us define $A_pX$ to be the subset of four-forms $\Phi_p \in \Lambda^4 T^*_p X$ for which there exists an isomorphism between $T_p X$ and $\mathbb{R}^8$ such that $\Phi_p$ is identified with $\Phi^0_0$. It follows that $A_pX$ is isomorphic to $GL(8, \mathbb{R})/Spin(7)$. Let $AX$ be the bundle over $X$ with fiber $A_pX$ for each $p \in X$. We say that a four-form $\Phi$ on $X$ is admissible if $\Phi_p \in A_pX$ for each $p \in X$. In other words, admissible forms are those that can be ‘reached’ from $\Phi^0_0$, at each point in $X$. It follows that there is a 1-1 correspondence between $Spin(7)$ structures and admissible four-forms $\Phi \in AX$.

The isotropy group of a nonzero Majorana-Weyl spinor of $Spin(8)$, is $Spin(7)$. This simply follows from the fact that under $Spin(7) \subset Spin(8)$ the chiral spinor representation of $Spin(8)$ decomposes as $8 \to 7 + 1$, i.e. there is a singlet in the decomposition. Hence a nowhere-vanishing Majorana-Weyl spinor of $Spin(8)$ induces a reduction of the structure group of $X$ to $Spin(7)$. An equivalent way to understand the reduction of the structure group is by noting that there is a nowhere-vanishing self-dual four-form which can be constructed as a bilinear of the chiral spinor.

Let $I_\pm$ be the isotropy groups of $\xi^\pm$. The isotropy group $I_+ \cap I_-$ of $\xi = \xi^+ \oplus \xi^-$ induces a local reduction of the structure group. If both Majorana-Weyl spinors $\xi^\pm$ are nowhere-vanishing, the structure group of $X$ reduces to the common subgroup of the two $Spin(7)$ structures: $Spin(7)_+ \cap Spin(7)_- = G_2$. The reduction of the structure group to $G_2$ can be deduced alternatively from the fact that in this case there exist a nowhere-vanishing vector and a three-form on $X$, which can be constructed as a bilinears of $\xi^+$ and $\xi^-$.

In general, both chiral spinors may have zeros. At a point where $\xi^+$ ($\xi^-$) vanishes, $I_+$ ($I_-$) is enhanced to $Spin(8)$ and the isotropy group of $\xi = \xi^+ \oplus \xi^-$ is enhanced to $I_+ \cap I_- = Spin(7)_\mp$. This, however, does not induce a reduction of the structure group to $Spin(7)$ unless, as explained in the previous paragraph, $X$ supports a nowhere-vanishing Majorana-Weyl spinor. Roughly-speaking, the isotropy group of $\xi$ is not, in general, a fixed $Spin(7)$ subgroup of $Spin(8)$ – as is required for a reduction of the structure group: as one moves around in $X$, $I_+ \cap I_-$ ‘rotates’ inside $Spin(8)$.

Nevertheless, it is possible to translate this situation to an honest $Spin(7)$ reduction of the structure group not of $X$ itself, but of an associated nine-manifold. First, let us recall some useful facts about $Pin$ vs $Spin$ groups. The reader can consult, e.g., [24] for more details. The group $Pin(n)$ sits inside $Cliff(n)$, therefore the irreducible representations of $Cliff(n)$ restrict to representations of $Pin(n)$ – which actually turn out to be irreducible as well. In particular, the real irreducible representation of $Pin(8)$ is the restriction of the real irreducible representation of $Cliff(8)$ – the sixteen-dimensional Majorana spinor in eight dimensions. Similarly, since $Spin(n)$ sits inside $Cliff_0(n)$ (the even part of the Clifford algebra), the irreducible representations of $Cliff_0(n)$ restrict to representations of $Spin(n)$ – which also turn out to be irreducible. Furthermore, there is an important isomorphism:

$$Cliff(n) \cong Cliff_0(n + 1). \quad (2.5)$$

Coming back to physics: we are considering M-theory compactifications on an eight-manifold $X$. Supersymmetry imposes the existence of a nowhere-vanishing real pinor $\xi$ on $X$. Tensoring $X$ by a constant circle $S^1$, we obtain a compact nine-dimensional product manifold $Y := X \times S^1$. As can be seen from (2.5), the nowhere-vanishing pinor $\xi$ on $X$ lifts to a nowhere-vanishing spinor on $Y$ in the real, sixteen-dimensional irreducible representation of $Spin(9)$. Of course $\xi$, thought of as a spinor on
Y, does not depend on the co-ordinate of $S^1$. It is well-known that the existence of a nowhere-vanishing spinor on a nine-manifold $Y$ induces the reduction of the structure group of $Y$ to $Spin(7)$

Alternatively, the reduction of the structure group of $Y$ can be understood as follows: Since $\xi$ is nowhere-vanishing, the Majorana spinors $\varepsilon^{\pm} := \frac{1}{\sqrt{2}}(\xi^+ \pm \xi^-)$ (the normalization is for later convenience) are also nowhere-vanishing and each of them induces a reduction of the structure group of $Y$ to $Spin(7)$. At the points in $Y$ where $\varepsilon^{\pm}$ are not parallel, the isotropy group of $\varepsilon^{\pm}$ is reduced to $G_2 = Spin(7) \cap Spin(7)$. However, $\varepsilon^+$ becomes parallel to $\varepsilon^-$ precisely at the points where either of $\xi^{\pm}$ vanishes. At these points the isotropy group is enhanced to $Spin(7)$. This point-of-view is better suited for the description in terms of generalized $Spin(7)$ structures, which we introduce in section 4.1 below.

The topological obstruction to the existence of a nowhere-vanishing Majorana-Weyl spinor on $X$ is known \cite{25,26}: it is equivalent to the condition that the Euler number of $X$ be given by

$$\chi(X) = \pm \frac{1}{2} \int_X (p_2 - \frac{1}{4} p_1^2) , \quad (2.6)$$

where $p_{1,2}$ are the first and second Pontrjagin forms. The sign on the right-hand side of the equation above depends on the chirality of the nowhere-vanishing spinor. As is follows immediately from (2.6), requiring that nowhere-vanishing Majorana-Weyl spinors of both chiralities exist, leads to the condition that the Euler number of $X$ vanishes. This, of course, is exactly the topological condition for the existence of a nowhere-vanishing vector field on $X$. Indeed, a vector field can be constructed as a bilinear of $\xi^+$ and $\xi^-$ and, interestingly, equations (2.6) can be related to the condition $\chi(X) = 0$ by a certain triality rotation \cite{26}. As we have seen, in this case there is a reduction of the structure group to $G_2$. In the generic case, although there is a nowhere-vanishing Majorana spinor $\xi = \xi^+ \oplus \xi^-$ on $X$, both $\xi^{\pm}$ may have zeros; hence $X$ need not satisfy equation (2.6).

3. $\mathcal{N} = 1$ supersymmetry

The starting point of our analysis is the supersymmetry equations given in (3.5-3.8) below. We will now describe the Ansätze leading up to these equations, as well as some basic background on eleven-dimensional supergravity in order to establish conventions. This brief review follows \cite{19}.

The field content of eleven-dimensional supergravity consists of a metric, a Majorana vector-spinor (gravitino) and a four-form field strength $G$. We shall consider eleven-dimensional M-theory backgrounds of the form of a warped product $\mathcal{M} \times_w X$, where $X$ is an eight-manifold and $\mathcal{M}$ is three-dimensional Minkowski or AdS space. Explicitly, the metric Ansatz reads

$$ds_{11}^2 = e^{2\Delta}(ds_3^2 + g_{mn}dx^m dx^n) , \quad (3.1)$$

where $e^{2\Delta}$ is the warp factor and $ds_3^2$ is the metric on $\mathcal{M}$. For the convenience of the reader, we follow the notation of \cite{19}. The most general four-form flux Ansatz respecting three-dimensional covariance

\[\text{Recall that } Spin(9) \text{ acts transitively on the unit sphere in sixteen dimensions, } S^{15} \cong Spin(9)/Spin(7), \text{ and that a real, sixteen-dimensional unit spinor on } Y \text{ implies the existence of a global section of the sphere bundle over } Y \text{ with fiber } S^{15}.\]
reads

\[ G = e^{3\Delta} (F + Vol_3 \wedge f) , \]  

(3.2)

where \( Vol_3 \) is the volume element along the noncompact directions and \( f (F) \) is a one-form (four-form) on \( X \). Finally, the eleven-dimensional supersymmetry parameter \( \zeta \) splits into a direct product of a Majorana spinor \( \psi \) on \( M \) and a spinor \( \xi = \xi^+ \oplus \xi^- \) on \( X \):

\[ \zeta = e^{-\Delta} \psi \otimes (\xi^+ \oplus \xi^-) . \]  

(3.3)

More precisely, \( \xi \) is a section of the real spin sub-bundle \( S^+_R \oplus S^-_R \) on \( X \), where \( S^+ \oplus S^- \) is the spin bundle on \( X \) and \( S^\pm = S^\pm_R \otimes \mathbb{C} \). Furthermore, since \( M \) is Minkowski or AdS, \( \psi \) is constrained to satisfy

\[ \nabla_\mu \psi + m \gamma_\mu \psi = 0 , \]  

(3.4)

where \( m \) is a massive parameter proportional to the inverse radius of \( M \). Substituting our Ansätze into the supersymmetry transformations of eleven-dimensional supergravity, we arrive at the following equations.

**Internal gravitino:**

\[ 0 = \nabla_m \xi^+ + \frac{1}{24} F_{mpqr} \gamma^{pqr} \xi^- - \frac{1}{4} f_n \gamma^m \xi^+ - m \gamma_m \xi^- \]  

(3.5)

\[ 0 = \nabla_m \xi^- + \frac{1}{24} F_{mpqr} \gamma^{pqr} \xi^+ + \frac{1}{4} f_n \gamma^m \xi^- + m \gamma_m \xi^+ . \]  

(3.6)

**External gravitino:**

\[ 0 = \frac{1}{2} \gamma^m \partial_m \Delta \xi^+ - \frac{1}{128} F_{mpqr} \gamma^{mpqr} \xi^- - \frac{1}{6} \gamma_n f_n \xi^+ + m \xi^- \]  

(3.7)

\[ 0 = \frac{1}{2} \gamma^m \partial_m \Delta \xi^- + \frac{1}{128} F_{mpqr} \gamma^{mpqr} \xi^+ + \frac{1}{6} \gamma_n f_n \xi^- - m \xi^+ . \]  

(3.8)

We have thus rewritten the eleven-dimensional supersymmetry transformations purely in terms of fields on \( X \).

In addition to the supersymmetry equations, a solution of eleven-dimensional supergravity should satisfy the Bianchi identities and the equations-of-motion. It can be shown that these take the form\(^2\)

\[ 0 = d(e^{3\Delta} F) \]

\[ 0 = e^{-6\Delta} d(e^{6\Delta} \star f) - \frac{1}{2} F \wedge F \]

\[ 0 = e^{-6\Delta} d(e^{6\Delta} \star F) - f \wedge F . \]  

(3.9)

One can show that, under a certain mild condition which is satisfied for the backgrounds considered in this paper, the supersymmetry equations together with the Bianchi identities and equations-of-motion

\(^2\)The analysis of [19] suggests that the last line in (3.9) may be redundant, i.e. it may follow from the supersymmetry equations and the remaining equations in (3.4). We thank D. Martelli for discussions on this point.
imply the Einstein equations. Similar integrability statements also hold for IIA and IIB supergravities.

Note that setting \( m = 0 \) excludes any solutions with nonzero fluxes if \( X \) is smooth and compact. As noted in [19], this can be seen immediately from the scalar part of the Einstein equation:

\[
e^{-9\Delta}\Box e^{9\Delta} - \frac{3}{2}|F|^2 - 3|f|^2 + 72m^2 = 0 .
\]

Integrating by parts gives \( f, F = 0 \). This no-go ‘theorem’ can be evaded by allowing the equations-of-motion and/or Bianchi identities to be modified, e.g. by introducing source terms or higher-order curvature corrections.

A well-known higher-order correction is the one related to the M five-brane anomaly

\[
d\ast G + \frac{1}{2} G \wedge G = \beta X_8 ,
\]

where \( \beta \) is a constant of order \( l_{\text{Planck}}^6 \) and \( X_8 \) is proportional to the same combination of Pontrjagin forms appearing on the right-hand side of (2.6). However, generally it is inconsistent to only include the correction (3.11) without considering the corresponding order-\( l_{\text{Planck}}^6 \) corrections to the supersymmetry equations. The latter corrections are, unfortunately, unknown to date.

The implications of the supersymmetry equations above are examined in section 4.1 from the point of view of generalized Spin(7) structures. The more conventional approach is pursued in section 3.1.

Before we close this section, let us make an observation which will be important in the following: as we explain in appendix D, it follows from (3.5, 3.6) that the Majorana spinor \( \xi \) has constant norm, which we can normalize to unity without loss of generality:

\[
|\xi|^2 = |\xi^+|^2 + |\xi^-|^2 = 1 .
\]

This equation was first noticed in [19].

3.1 Analysis

It follows from equation (3.12) that at each point \( p \) in \( X \) at least one of \( \xi^\pm \), let us say \( \xi^+ \) for concreteness, is non-vanishing. In an open set around \( p \), we can parameterize:

\[
\xi^+ = \frac{1}{\sqrt{1 + L^2}} \eta,
\]

\[
\xi^- = \frac{L_m}{\sqrt{1 + L^2}} \gamma^m \eta ,
\]

where \( \eta \) has unit norm: \( |\eta|^2 = 1 \). Note that the one-form \( L \) can be thought of as a \( \xi^+, \xi^- \) bilinear. Moreover, we can define a self-dual four-form \( \Phi \) as an \( \eta \)-bilinear via

\[
\Phi_{mpqr} := \eta \gamma_{mpqr} \eta .
\]

\[\text{In certain cases, e.g. compactification on ‘large’ eight-manifolds, it is in fact consistent to ignore all higher-order corrections except for the one in (3.11), see [31] for a detailed argument.}\]

\[\text{In our conventions the real spinor } \eta \text{ satisfies } \eta^\dagger = \eta^{Tr} C, \text{ where } C \text{ is the charge-conjugation matrix. We use } C \text{ to raise/lower indices on the gamma-matrices, so that the notation } \eta \gamma_m \eta \text{ is a shorthand for } \eta^{Tr} (C\gamma_m) \eta, \text{ etc.}\]
As was explained in detail in section 2.1, the existence of the four-form defined in (3.14) above induces a Spin(7)-structure on $X$; therefore, one can decompose all fields in terms of irreducible representations of Spin(7). As was mentioned in section 2, it is very useful to be able to translate back and forth between the spinor and the G-structure language; in this way the supersymmetry equations can be expressed as a set of purely algebraic relations. For the case at hand, the schematic equation (2.3) is nothing but the statement that the following two equations are equivalent:

\[
\begin{align*}
\partial_{[m} \Phi_{pqrs]} &= -8 \Phi_{[mpqr,\omega^1_s]} - \frac{4}{15} \varepsilon_{mpqrs} ijk \omega^2_{ijk} \\
\nabla_m \eta &= \left\{ \omega^1_n \gamma^m n + \omega^2_{mpq} \gamma^{pq} \right\} \eta,
\end{align*}
\]

(3.15)

where $\omega^1$ transforms in the $8$ of Spin(7) while $\omega^2$ transforms in the $48$. Note that $d\Phi$ being a five-form it transforms in the $8 \oplus 48$ of Spin(7), hence the decomposition on the right-hand side of the first line of (3.15). $\omega^{1,2}$ generate the two modules of the intrinsic torsion of a manifold of Spin(7) structure [32]. The equivalence of the two equations in (3.15), is proven in appendix E.

 Skipping all the details of the derivation, which can be found in appendix D, the supersymmetry conditions are equivalent to the following equations: the one-form $L$ is constrained to satisfy

\[
\begin{align*}
d\left( e^{2\Delta} \frac{L}{1 + L^2} \right) &= 0 \\
e^{-12\Delta} \star d \star \left( e^{12\Delta} \frac{L}{1 + L^2} \right) - 4m \left( 1 - \frac{L^2}{1 + L^2} \right) &= 0,
\end{align*}
\]

(3.16)

where here and in the remainder of this paper the Hodge star is taken with respect to the internal eight-dimensional space. Moreover, all flux components except for the $27$ component of $F$ are solved for in terms of $L$ and the warp factor:
\[
\begin{align*}
&f = e^{-3\Delta} \left( e^{3\Delta} \frac{1 - L^2}{1 + L^2} \right) + 8m \frac{L}{1 + L^2} \\
&\frac{1}{12} F^1 = e^{-3\Delta} L^i \partial_i \left( \frac{e^{3\Delta}}{1 + L^2} \right) - m \frac{3 - L^2}{1 + L^2} \\
&\frac{1}{96} F^7_{rs} = - e^{-3\Delta} (P^7)_{pq} L_p \partial_q \left( \frac{e^{3\Delta}}{1 + L^2} \right) \\
&\frac{1}{24} F^35_{mn} = - \nabla_{(m} L_{n)} - \frac{1}{4} \Phi (m \otimes F^7)_{ij} L_k + \frac{3}{7(1 + L^2)^2} \left( L_m L_n + \frac{L^2}{6} g_{mn} \right) L^i \nabla_i L^2 \\
&\quad - \frac{9}{7(1 + L^2)} \left\{ L_m L_n + \frac{7 + 8L^2}{6} g_{mn} \right\} L^i \nabla_i L^2 \\
&\quad + \frac{3L^2}{1 + L^2} L_{(m} \partial_{n)} \Delta + \frac{m}{14(1 + L^2)} \left\{ 8(L^2 - 3)L_m L_n + (7 + 3L^2 - 8L^4) g_{mn} \right\}
\end{align*}
\]

(3.17)

where the explicit decomposition of \( F \) in terms of irreducible representations of \( Spin(7) \) and the explanation of the definitions entering the equations above, are given in the appendix. As noted in the introduction, in open sets where neither of \( \xi^\pm \) vanishes, the above equations should reduce to the corresponding formulae given in [19], to the extent they overlap (some of the flux components were not given explicitly in [19]). Finally, the intrinsic torsion is determined via

\[
\begin{align*}
\omega^1_m &= m \frac{2}{2} L_m + \frac{3}{4} \partial_m \Delta + \frac{1}{168} (L_m F^1 - L^i F^7_{im}) \\
\omega^2_{mpq} &= \frac{1}{192} (L \otimes F^7)_{mpq} + \frac{1}{4} (L \otimes F^7 \otimes F)_{mpq}
\end{align*}
\]

(3.18)

### 3.2 Small-flux approximation

A special solution to the supersymmetry equations (3.5-3.8), the Bianchi identities and the equations-of-motion (3.9), is obtained when the warp factor and all flux vanishes \( (\Delta, f, F = 0) \), \( \mathcal{M} \) is three-dimensional Minkowski space \( (m = 0) \) and \( X \) is a manifold of \( Spin(7) \) holonomy \( (\omega^{1,2} = 0) \). In this section we would like to perform a small perturbation around the special-holonomy solution; this amounts to a small-flux approximation. Note that this is an expansion around the point where the \( G_2 = Spin(7)_+ \cap Spin(7)_- \) structure breaks down, and so it cannot be described by the formalism of [19].

For each field \( S \), let us make a perturbative expansion

\[
S = \sum_{n=0} S^{(n)} \varepsilon^n ,
\]

(3.19)
where $\varepsilon$ is a small parameter, so that the special-holonomy solution is recovered in the $\varepsilon \to 0$ limit. Equations (3.17) determine the flux components:

\begin{align*}
F^1 &= -36m^{(1)} \varepsilon + \mathcal{O}(\varepsilon^2) \\
F^7_{mn} &= \mathcal{O}(\varepsilon^2) \\
F^{35}_{mn} &= \left(-24\nabla_m L^{(1)}_n + 12g_{mn}m^{(1)} \right) \varepsilon + \mathcal{O}(\varepsilon^2),
\end{align*}

where the metric and the Levi-Civita connection above are those of the unperturbed special-holonomy solution. The 27 component of the flux is of order $\mathcal{O}(\varepsilon)$, but is otherwise unrestricted by the supersymmetry equations. Moreover, equations (3.18) give

\begin{align*}
\omega^1_m &= \frac{3}{4}\partial_m \Delta^{(1)} + \mathcal{O}(\varepsilon^2) \\
\omega^{mpq} &= \mathcal{O}(\varepsilon^2),
\end{align*}

It follows from the form of the intrinsic torsion (see e.g. [33]) that to order $\mathcal{O}(\varepsilon^2)$ the eight-manifold is conformally special-holonomy. Finally, to order $\mathcal{O}(\varepsilon^2)$, equations (3.16) are equivalent to

\begin{align*}
\nabla^m L^{(1)}_m &= 4m^{(1)} \\
\nabla_{[mn]} L^{(1)}_n &= 0,
\end{align*}

where again the Levi-Civita connection above is that of the special-holonomy metric. Integrating the first line by parts in the case where $X$ is smooth and compact, we conclude that $m^{(1)} = 0$. By the same reasoning, it can be seen by induction that $m$ vanishes to all orders in $\varepsilon$. It follows that, as noted in section 3, all flux vanishes and we get back the special-holonomy solution.

Nontrivial solutions can be obtained if $X$ is noncompact. In this case equations (3.22) are solved for

\begin{align*}
L^{(1)}_m &= \partial_m \phi \\
\Box \phi &= 4m^{(1)},
\end{align*}

where $\phi$ is a scalar on $X$ with dimensions of length and the box operator is taken with respect to the unperturbed special-holonomy metric. The Bianchi identities and the equations-of-motion impose the conditions that $\Delta^{(1)}$ should be harmonic and that $F^{27}$ should be closed. Neglecting corrections of order $\mathcal{O}(\varepsilon^2)$, it can be shown that there are no further conditions \footnote{To arrive at this result the only nontrivial step is to prove that $I_{m_1...m_5} := \Phi_{[m_1...m_5}^{\ p}R_{m_4m_5]}^{\ p}L_q$ vanishes, where the Riemann tensor is with respect to the special-holonomy connection. This can be seen as follows: for fixed $m,n$, $R_{mn,pq}$ can be viewed as an antisymmetric matrix with indices $p,q$; i.e. it transforms in the $21 + 7$ of $\text{spin}(7)$. However, since the spinor $\eta$ is parallel with respect to the connection, it follows that $R_{mn,pq}^{\ rspq}\eta = 0$ and hence the 21 component is projected out while the 7 component is set to zero (cf. equation (3.4)). I.e. for fixed $m,n$ (or for fixed $p,q$, thanks to the symmetry properties of the Riemann tensor) $R_{mn,pq}$ transforms in the 21 of $\text{spin}(7)$. Furthermore, as follows from the symmetry of the free indices and the previous discussion, $R_{mn,p}^{\ p}L_q$ transforms in the $21 \otimes 8 = 8 \oplus 48 \oplus 112$. On the other hand, $I_{m_1...m_5}$ is a five-form and hence it transforms in the $8 \oplus 48$ of $\text{spin}(7)$; therefore the 112 representation is projected out. The remaining $8 \oplus 48$ representations are generated by $R_{[mn,p]}^{\ p}L_q$, which vanishes by virtue of the symmetries of the Riemann tensor, and $g_{mn}R_{p}^{\ p}L_q$, which vanishes by virtue of the fact that every manifold of special holonomy is Ricci-flat. It follows that $I_{m_1...m_5}$ vanishes.}.
As an explicit example, let us consider a small perturbation around the noncompact Spin(7)-holonomy metric of reference [21, 22]:

\[
ds^2 = \left(1 - \left(\frac{l}{r}\right)^{10/3}\right)^{-1}dr^2 + \frac{9}{100}r^2\left(1 - \left(\frac{l}{r}\right)^{10/3}\right)(\sigma_i - A^i)^2 + \frac{9}{20}r^2d\Omega_4^2 \tag{3.24},
\]

where \( l \leq r < \infty \), \( d\Omega_4^2 \) is the metric of the unit four-sphere \( S^4 \), \( \{\sigma_i; i = 1, 2, 3\} \) are left-invariant \( SU(2) \) one-forms and \( A^i \) is the connection of a Yang-Mills instanton on \( S^4 \). Moreover, let us assume that \( \phi = \phi(r) \). For \( r \gg l \), the solution to equation (3.23) behaves as

\[
\phi \sim Q_1 + Q_2 \frac{1}{\delta^2} + O(\delta),
\]

where \( \delta := l/r \) and \( Q_{1,2} \) are constants (\( Q_2 \) depends on \( m \)). On the other hand, when \( r \) approaches \( l \) we have

\[
\phi \sim Q'_1 + Q'_2 \left(\frac{1}{\delta} + \frac{8}{3}\log(\delta)\right) + O(\delta),
\]

where \( Q'_{1,2} \) are constants (\( Q'_2 \) depends on \( m \)) and \( \delta := r/l - 1 \). In conclusion: for \( m \neq 0 \) (i.e. for \( \mathcal{M} \) AdS), \( L^2 \sim |\partial \phi|^2 \) blows up near \( l, \infty \), which is contrary to our assumption that \( L \) is perturbatively small. Hence, the solution can only be trusted for intermediate distances \( 1/\varepsilon >> r/l >> \varepsilon \). Note however that for \( m = 0 \) (i.e. for \( \mathcal{M} \) Minkowski) \( Q_2 \) vanishes and the solution to (3.23) is regular for large distances \( r/l >> \varepsilon \).

### 4. Generalized G-structures

In this section, after some preliminaries, we give the definition of generalized Spin(7) structures in nine dimensions and explain how they arise naturally in the context of supersymmetric M-theory compactifications on eight-manifolds. Generalized G-structures were first introduced in [8]. Generalized Spin(7) structures in eight dimensions were first examined by F. Witt in [15].

Consider the direct sum of the tangent and cotangent bundle \( T \oplus T^* \) of a \( d \)-dimensional manifold \( X \). There is a natural action of \( T \oplus T^* \) on forms, whereby every vector acts by contraction and every form by exterior multiplication. Explicitly: if \( V \) is a vector on \( X \) and \( U, \Omega \) are forms, we define

\[
(V + U) \cdot \Omega = \iota_V \Omega + U \wedge \Omega. \tag{4.1}
\]

As this action squares to the identity, there is an associated Clifford algebra \( \text{Cliff}(T \oplus T^*) \) and an induced isomorphism

\[
\text{Cliff}(T \oplus T^*) \cong \text{End}(\Lambda^*) \tag{4.2}.
\]

A basis of the Clifford algebra on \( T \oplus T^* \)

\[
\{\gamma^m, \gamma^n\} = 0; \quad \{\gamma_m, \gamma_n\} = 0; \quad \{\gamma^m, \gamma_n\} = \delta^m_n \tag{4.3}
\]

is given explicitly by \( \gamma^m := dx^m \wedge, \gamma_n := \iota_n \). It follows from the isomorphism (4.2) above that (sums of) forms on \( X \) can be identified with spinors of \( T \oplus T^* \). Moreover, the latter can be thought of as bispinors on \( X \). We thus obtain

\[
\text{forms} \longleftrightarrow \text{spinors on } T \oplus T^* \longleftrightarrow \text{bispinors on } X. \tag{4.4}
\]

The identification of sums of forms with bispinors is, of course, explicitly realized by Fierzing.
4.1 Generalized Spin(7) structures

Coming back to our eight-dimensional case, we define the following bispinors

\[ \Phi^\pm := \xi^\pm \otimes \xi^\pm = \frac{1}{8} P_\pm \left\{ \Phi^\pm + \frac{1}{2 \cdot 4!} \Phi^\pm_{m_1 \ldots m_4} \gamma^{m_1 \ldots m_4} + \frac{1}{8!} \Phi^\pm_{m_1 \ldots m_8} \gamma^{m_1 \ldots m_8} \right\}, \]  

(4.5)

where \( P_\pm := \frac{1}{2}(1 \pm \gamma_9) \) is the chirality projector and \( \Phi^\pm_{m_1 \ldots m_p} := \xi^\pm \gamma_{m_1 \ldots m_p} \xi^\pm \). By a slight abuse of notation, we use the same letter to denote both the bispinor and the associated forms. It should be clear from the context which one is meant in each case. It will prove more convenient to work with the linear combinations: \( \Psi^\pm := \frac{1}{2}(\Phi^+ \pm \Phi^-) \). Moreover we define

\[ \tilde{\Psi} := \xi^+ \otimes \xi^- = \frac{1}{8} P_+ \sum_{p=odd} \frac{1}{p!} \tilde{\Psi}_{m_1 \ldots m_p} \gamma^{m_1 \ldots m_p}, \]  

(4.6)

where \( \tilde{\Psi}_{m_1 \ldots m_p} := \xi^+ \gamma_{m_1 \ldots m_p} \xi^- \). In the following we will find it useful to define the combinations (cf. also equations (F.7,F.8) of appendix F):

\[ \hat{\Psi} := \xi^+ \otimes \xi^- = \frac{1}{2}(\Psi^+ \pm \Psi^-). \]  

(4.7)

The Majorana spinors (real pinors) \( \epsilon^\pm := \frac{1}{\sqrt{2}}(\xi^+ \pm \xi^-) \) are nowhere-vanishing on \( X \), since \( 2|\epsilon|^2 = |\xi^+|^2 + |\xi^-|^2 = 1 \). Hence any bispinors constructed out of the \( \epsilon^\pm \)’s are also nowhere-vanishing. Setting

\[ \rho^\pm := \epsilon^\pm \otimes \epsilon^\pm = \Psi^+ \pm \tilde{\Psi} \]  

\[ \hat{\rho}^\pm := \epsilon^\pm \otimes \epsilon^- = \Psi^- \mp \tilde{\Psi}^+, \]  

(4.7)

we note that \( \Psi^\pm, \tilde{\Psi}^\pm \) can be expressed as linear combinations of \( \rho, \hat{\rho} \). As discussed in detail in section 2.1, these bispinors on \( X \) lift to bispinors on \( Y = X \times S^1 \). We shall call the pair \( (\rho, \hat{\rho}) \) a generalised \( \text{Spin}(7) \) structure on \( Y \). Note that \( (\rho, \hat{\rho}) \) induce a reduction of the structure group \( \text{Spin}(9,9) \) of \( TY \oplus T^*Y \) to \( \text{Spin}(7) \times \text{Spin}(7) \). This follows from the fact that \( \epsilon^\pm \) are nowhere-vanishing and therefore each of them induces a reduction of the structure group of \( Y \) to \( \text{Spin}(7) \), as explained in 2.1.

As we show in appendix F, \( \mathcal{N} = 1 \) supersymmetry implies that the generalised \( \text{Spin}(7) \) structure, or equivalently the bispinors \( \Psi^\pm, \tilde{\Psi}^\pm \), satisfy the following differential equations

\[
\begin{align*}
0 &= d\Psi^+ + F \wedge \tilde{\Psi}^- \\
0 &= e^{-3\Delta} d(e^{3\Delta} \Psi^-) + *F \wedge \tilde{\Psi}^- - f \wedge \Psi^+ + 4m \tilde{\Psi}^- \\
0 &= e^{-3\Delta/2} d(e^{3\Delta/2} \Psi^-) \\
0 &= e^{-3\Delta/2} d(e^{3\Delta/2} \tilde{\Psi}^+) + 2(*F \wedge \Psi^+ - F \wedge \Psi^-) + 8m \Psi^+. 
\end{align*}
\]  

(4.8)

In the terminology of \([4, 7]\), the equations (4.8) above are the ‘form picture’ of the \( \mathcal{N} = 1 \) supersymmetry equations given in the ‘spinor picture’ in (3.5-3.8). Note that, as is easy to show, the integrability of (4.8) follows from the equations-of-motion and the Bianchi identities.
4.2 Reduction to seven dimensions

In the case where \( X \) is of the form \( Z \times S^1 \) and assuming no fields depend on the coordinate of \( S^1 \), we can perform a reduction to seven dimensions – upon which \( \xi^\pm \) and \( \epsilon^\pm \) transform in the \( 8 \) of \( Spin(7) \). Since as we noted above \( \epsilon^\pm \) are nowhere-vanishing, each of them gives rise to a \( G_{2\pm} \subset Spin(7) \) structure on \( Z \). Indeed, \( G_2 \) is the isotropy group of a fundamental spinor inside \( Spin(7) \). Alternatively, this can be seen by noting that under \( G_2 \subset Spin(7) \) the fundamental spinor representation decomposes as \( 8 \rightarrow 7 + 1 \), i.e. there is a singlet in the decomposition. If \( \epsilon^\pm \) are nowhere parallel (equivalently: if \( \xi^\pm \) are nowhere-vanishing), there is a further reduction of the structure group of \( Z \) to the common subgroup \( G_{2+} \cap G_{2-} = SU(3) \). In the generic case there are points in \( Z \) where \( \epsilon^\pm \) become parallel. At these points the \( SU(3) \) structure is enhanced to \( G_{2+} \cap G_{2-} = G_2 \). This situation is best described in the language of generalized \( G_2 \) structures in seven dimensions [4, 7].

5. Conclusions

We have presented a formalism for supersymmetric M-theory compactifications on eight-manifolds \( X \), based on the group \( Spin(7) \). This is the most suitable language in which to describe compactifications on eight-manifolds of \( Spin(7) \) structure, and/or small-flux perturbations around compactifications on manifolds of \( Spin(7) \) holonomy. Although supersymmetry does not, in general, imply the reduction of the structure group of \( X \) itself, our analysis leads naturally to the emergence of a nine-dimensional manifold \( Y = X \times S^1 \) whose structure group is reduced to \( Spin(7) \). This is reminiscent of the connection between M- and F-theory: in the case where \( X \) admits an elliptic fibration, M-theory on \( X \) is equivalent to F-theory on \( X \times S^1 \) [38]. It would be very interesting to explore this similarity further.

In eight dimensions there exists a Hitchin functional involving a certain three-form and its Hodge-dual five-form [9]. This does not seem to be related to the case considered here: we generally do not have any nowhere-vanishing three-form on \( X \). It would be interesting to explore whether such a functional can be constructed using the four-forms \( \Phi^\pm \) of section 4.1 and what should be the generalization of stability in this case. A related point is that, as we have already noted in the introduction, in ten dimensions the NS and RR fields play quite different roles with respect to the Hitchin functional construction [7]; this distinction disappears upon lifting to M-theory. It would also be desirable to know whether equations (4.8) can be interpreted as some sort of integrability condition for the generalized \( Spin(7) \) structures.

In type II theories the generalized picture provides a natural framework for T-duality in topological models [34, 35, 36]. It would be interesting to explore this issue in the context corresponding to the setup of this paper, i.e. in the context of an M- or F-theory topological \( \sigma \)-model with target space the eight-manifold \( X \). We expect T-duality to act as a sign flip: \( \xi^- \rightarrow -\xi^+ \). This amounts to an exchange \( \epsilon^+ \leftrightarrow \epsilon^- \) (cf. section 4.1), in analogy to the situation in seven and six dimensions.

At a more mundane level, the present paper opens up the possibility for supersymmetric solutions with all fluxes turned on and with an internal manifold in any of the four classes of \( Spin(7) \) manifolds. Any explicit examples of such manifolds are, of course, desirable and could provide us with interesting
physics; the physics of M theory on eight manifolds is already very rich, even in the case where the internal manifold is special-holonomy. Even in the absence of an explicit metric, the characterization of the most general $\mathcal{N} = 1$ backgrounds given in this paper should suffice for a Kaluza-Klein reduction and the derivation of the resulting low-energy supergravity in three dimensions. It will be interesting to pursue this point further.

6. Acknowledgment

I would like to thank Claus Jeschek for valuable discussions and Dario Martelli for email correspondence. I am also grateful to Frederik Witt for useful discussions and explanations, and to the referee of JHEP for useful suggestions.

A. Gamma-matrix identities in 8d

The gamma matrices in eight dimensions have the following properties

Symmetry:

$$(C\gamma(n))^T = (-)^{\frac{1}{2}n(n-1)}C\gamma(n),$$

where $C$ is the charge-conjugation matrix.

Hodge-duality:

$$\ast\gamma(n) = (-)^{\frac{1}{2}n(n+1)}\gamma(8-n)\gamma_9,$$

where $\gamma_9$ is the chirality matrix.

B. Identities relating to the $\text{Spin}(7)$ structure

In this section we give a number of identities which we have used repeatedly in this paper. These can be proved either by Fierzing or by fixing a special basis for the spinor $\eta$, as in e.g. [37]. Given a positive-chirality Majorana spinor $\eta$ of unit norm, we can define a self-dual four-form as in (3.14), which can be seen to satisfy the following identities

$$\Phi^i_{jkl}\Phi^j_{ikm} = 42\delta^i_k$$
$$\Phi^i_{jkl}\Phi_{ijpq} = 12\delta^{kl}_{pq} - 4\Phi^{kl}_{pq}$$
$$\Phi^i_{jklm}\Phi_{ipqr} = 6\delta^{klm}_{pqr} - 9\Phi^{[kl}_{[pq}\delta^{m]}_{r]}.$$

Moreover, we have

$$\gamma_{ij}\eta = -\frac{1}{6}\Phi_{ijkl}\gamma_{kl}\eta$$
$$\gamma_{ijkl}\eta = -\Phi_{ijkl}\gamma\eta$$
$$\gamma_{ijkl}\eta = \Phi_{ijkm}\gamma_{[m]}\eta + \Phi_{ijkl}\eta$$
$$\gamma_{ijklm}\eta = 5\Phi_{ijklm}\eta.$$
We define the following projectors, acting on a second-rank tensor, onto the 7, 35 of Spin(7):

\[
(P^7)_{mn}^{pq} := \frac{1}{4} \left( \delta_m^p \delta_n^q - \frac{1}{2} \Phi_{mn}^{pq} \right) \quad (B.3)
\]

\[
(P^{21})_{mn}^{pq} := \frac{3}{4} \left( \delta_m^p \delta_n^q + \frac{1}{6} \Phi_{mn}^{pq} \right) \quad (B.4)
\]

\[
(P^{35})_{mn}^{pq} := \delta_m^p \delta_n^q - \frac{1}{8} g_{mn} g^{pq} . \quad (B.5)
\]

A useful identity is

\[
(P^{21})_{pq}^{rs} \gamma^{pq} \eta = 0 . \quad (B.6)
\]

C. Spin(7) tensor decomposition

Let us decompose \( F_{mnpq} \) into irreducible representations

\[
F_{mnpq} = F^1_{mnpq} + F^7_{mnpq} + F^{27}_{mnpq} + F^{35}_{mnpq} . \quad (C.1)
\]

Expanding

\[
F^1_{mnpq} = \frac{1}{42} \Phi_{mnpq} F^1
\]

\[
F^7_{mnpq} = \frac{1}{24} \Phi_{mnp} \, i F^7_{qi}
\]

\[
F^{35}_{mnpq} = \frac{1}{6} \Phi_{mnp} \, i F^{35}_{qi} , \quad (C.2)
\]

where \( F^7_{mn} \) is antisymmetric in \( m, n \) whereas \( F^{35}_{mn} \) is symmetric and traceless, we obtain

\[
F_{ijkp} \Phi^{ijk} q = g_{pq} F^1 + F^7_{pq} + F^{35}_{pq} . \quad (C.3)
\]

In the above we have noted that

\[
F^{27}_{ijkp} \Phi^{ijk} q = 0 . \quad (C.4)
\]

This can be seen immediately as follows: the left-hand side transforms in the \( 8 \otimes 8 \) of Spin(7), however \( 8 \otimes 8 = 1 \oplus 7 \oplus 21 \oplus 35 \) and there is no 27 in the decomposition. Note that it follows from decomposition (C.2) that \( F^1, F^7 \) are self-dual while \( F^{35} \) is anti-self-dual.

In deriving (D.2) below, we shall need the following decompositions.

\[
L_m F^7_{pq} = (P^7)_{ij} \left( (L \otimes F^7)_{mij} + g_{mi}(L \otimes F^7)_j^8 \right) \quad (C.5)
\]

\[
L_m F^{35}_{pq} = (P^{35})_{ij} \left( \Phi_{mkl} (L \otimes F^{35})_{jkl} + g_{mi}(L \otimes F^{35})_j^8 \right) + \ldots \quad (C.6)
\]

where the ellipses stand for the irreducible representations which drop out of (D.2). These expansions can be inverted to give

\[
(L \otimes F^7)_m^8 = \frac{8}{3} L^i F^7_{im} \quad (C.7)
\]

\[
(L \otimes F^7)_{mpq} = 6 \left( L_{[m} F^7_{pq]} + \frac{1}{7} \Phi_{mpq} L^i F^7_{ij} \right) \quad (C.8)
\]
and

\[(L \otimes F^{35})^8_m = \frac{8}{35} L^i F^{35}_{im} \]  
\[(L \otimes F^{35})^{48}_{mpq} = \frac{3}{20} \left( L_i F^{35}_{jm} \Phi_{pq}^{ij} - \frac{1}{7} \Phi_{mpq}^{ij} L^i F^{35}_{ij} \right) . \]  
\[(C.9)\]

The reader can verify that the right-hand sides of (C.8, C.10) transform in the 48 of Spin(7), as they should. Moreover, note that

\[(L \otimes F^{27})^{48}_{mpq} := L^i F^{27}_{impq} \]  
\[(C.11)\]

also transforms in the 48. Indeed the right-hand side is a three-form and therefore transforms in the 8 \( \otimes 27 = 48 \oplus 168 \). On the other hand, the right-hand side is the product of \( L, F^{27} \), and therefore transforms in the 8 \( \otimes 27 = 48 \oplus 168 \). It follows that the right-hand side is in the 48 of Spin(7).

D. \( \mathcal{N} = 1 \) supersymmetry

In this appendix we give the details of the derivation of equations (3.12, 3.16-3.18). Taking decomposition (C.2) into account, the supersymmetry transformations (3.5-3.8) can be seen to be equivalent to the following conditions.

Equation (8.3):

\[0 = \partial_m R - (m + \frac{1}{24} F^1) L_m + \frac{1}{24} L^i (F^7_{im} - F^{35}_{im})\]  
\[0 = (P^7)^{pq}_{rs} \left\{ g_{mp} (\omega^1_q - \frac{1}{4} f_q + m L_q) - \omega^2_{mpq} + \frac{1}{24} (L_p \Phi^{ijk}_{q} F_{mij} + 6 L^i F_{impq}) \right\} , \]  
\[(D.1)\]

where we have parameterized \( \xi^+ = e^R \eta \), \( \xi^- = e^R L_m \gamma^m \eta \). Equation (3.6):

\[0 = \nabla_m L_n + \partial_m R L_n + \Phi^{ijk}_{mn} F_{mij} L_k - 2 \omega^2_{mn} L^i + g_{mn} (L^i \omega^1_i - \frac{1}{4} L^i f_i + \frac{1}{24} F^1 + m)\]  
\[- L_m (\omega^1_n - \frac{1}{4} f_n) - \Phi^{ij}_{mn} L_i (\omega^1_j + \frac{1}{4} f_j) + \frac{1}{24} (F^7_{mn} + F^{35}_{mn}) . \]  
\[(D.2)\]

Equation (3.7):

\[0 = m L_m + \frac{1}{2} (\partial_m \Delta - \frac{1}{3} f_m) + \frac{1}{36} L^i F^{35}_{im} . \]  
\[(D.3)\]

Equation (3.8):

\[0 = m - \frac{1}{2} L^i (\partial_i \Delta + \frac{1}{3} f_i) + \frac{1}{36} F^1\]  
\[0 = (P^7)^{pq}_{rs} \left\{ L_p \partial_q \Delta + \frac{1}{3} L_p f_q \right\} + \frac{1}{144} F^7_{rs} . \]  
\[(D.4)\]

Before proceeding to the derivation of (D.1-D.6), let us mention that equation (3.12) is derived as follows: multiplying (D.3) by \( L^m \) and using (D.1), we arrive at

\[\partial_m R = - \frac{L^m}{1 + L^2} \nabla_m L_n . \]  
\[(D.7)\]
Taking into account that $\xi^\pm$ can be rescaled by a real constant without loss of generality, it follows that

$$e^R = \frac{1}{\sqrt{1 + L^2}} ,$$

which is equivalent to equation (3.12).

In deriving equations (D.1, D.2, D.3, D.6) we have noted that the equation

$$A_{m \eta} + B_{m,pq} \gamma_{pq} \eta = 0 ,$$

where $(P^7)^{rs}_{pq} B_{m,rs} = B_{m,pq}$, is equivalent to $A_m$, $B_{m,pq} = 0$. This can be seen by multiplying on the left by $\eta$ and $\eta \gamma^{rs}$. Similarly, in deriving (D.3, D.4) we have noted that the equation

$$A_{m,n} \gamma^n \eta = 0$$

is equivalent to $A_{m,n} = 0$, as can be seen by multiplying on the left by $\eta \gamma_p$.

Equation (D.2) can be used to solve for the intrinsic torsion as in (3.18), by taking into account the following identities

$$0 = (P^7)^{pq}_{rs} \left\{ \Phi_{pq}^{ab} + 6 \delta_{[pq]}^a \delta_{[q]}^b \right\}$$

(D.11)

$$0 = (P^7)^{pq}_{rs} \left\{ L_p F^7_{mq} - \frac{1}{4} (L \otimes F^7)_{mpq}^{48} + \frac{5}{7} g_{mp} L_i F^7_{ij} \right\}$$

(D.12)

$$0 = (P^7)^{pq}_{rs} \left\{ L^i \Phi_{mpq}^{ij} F^7_{ij} + \frac{1}{4} (L \otimes F^7)_{mpq}^{48} - \frac{12}{7} g_{mp} L_i F^7_{ij} \right\}$$

(D.13)

$$0 = (P^7)^{pq}_{rs} \left\{ L_p F^{35}_{mq} + 5 (L \otimes F^{35})_{mpq}^{48} - \frac{1}{7} g_{mp} L_i F^{35}_{ij} \right\}$$

(D.14)

$$0 = (P^7)^{pq}_{rs} \left\{ L^i \Phi_{mpq}^{ij} F^{35}_{ij} + 5 (L \otimes F^{35})_{mpq}^{48} + \frac{6}{7} g_{mp} L_i F^{35}_{ij} \right\}$$

(D.15)

$$0 = (P^7)^{pq}_{rs} \left\{ L^i \Phi_{pq}^{ijk} F_{mijk} + L_i F_{jkmp} \Phi_{ij}^{pq} + 4 L_i F_{mpq} \right\}$$

(D.16)

In order to solve for the $F^{35}$ component of $F$, we first define

$$f_{mn}^{35} := F_{mn}^{35} + 2 \left\{ L_i F_{i(mL_n) - \frac{1}{8} g_{mn} L_i L_j f_{ij}^{35} \right\} + \frac{6}{7} L^i L^j F_{ij}^{35} \left( L_m L_n - \frac{1}{8} g_{mn} L^2 \right) ,$$

(D.17)

which is the combination that appears in the symmetric, traceless part of (D.3). Note that $f^{35}$ indeed transforms in the 35 of Spin(7). Equation (D.3) can then be used to solve for $f^{35}$:

$$\frac{1}{24} f_{mn}^{35} + \left( \nabla (m L_n) - \frac{1}{8} g_{mn} \nabla L \right) + \frac{1}{4} \Phi_{m \eta}^{ijk} (L \otimes F^{27})_{nij}^{48} L_k + \frac{5}{7} \left( L_m L_n - \frac{1}{8} g_{mn} L^2 \right) \left\{ m (1 + \frac{9}{5} L^2) + \frac{9}{5} L_i \partial_i \Delta \right\} = 0 ,$$

(D.18)

which can be solved for $F^{35}$ by inverting (D.17):

$$F_{mn}^{35} = f_{mn}^{35} - \frac{2 L^i f_{i(mL_n)}^{35} \right\} + \frac{1}{1 + L^2} \left\{ \frac{9}{14} L_m L_n + \frac{1}{4} g_{mn} (1 + \frac{3}{5} L^2) \right\} .$$

(D.19)
Note that $F_{mn}^{35}$ in (3.17) is traceless by virtue of
\[
\left\{ g^{mn} - 2 \frac{L^m L^n}{(1 + L^2)} \right\} \nabla_m L_n - 4m(1 - L^2) + 12L^i \partial_i \Delta = 0 ,
\]
which is obtained by tracing equation (D.3). A straightforward manipulation then leads to the second line of equation (3.16).

The 7 and 21 parts of (D.3) are treated similarly. Taking the identities
\[
0 = (P^7)_{pq} \left\{ \Phi_p \omega_{qij}^2 L_k + 4\omega_{pq}^2 L^i \right\}
\]
\[
0 = (P^{21})_{pq} \left\{ \Phi_p \omega_{qij}^2 L_k \right\}
\]
into account, we arrive at
\[
(\nabla_{[r} L_{s]})^7 = (P^7)^{mn}_{rs} \left\{ L_i \nabla_i L_m L_n - \frac{1}{2} L_m \partial_n L^2 + 3(1 + L^2) L_m \partial_n \Delta \right\}
\]
\[
(\nabla_{[r} L_{s]})^{21} = (P^{21})^{mn}_{rs} \left\{ L_i \nabla_i L_m L_n - \frac{1}{2} L_m \partial_n L^2 + 3(1 + L^2) L_m \partial_n \Delta \right\} .
\]

It is then straightforward to show that the equations above are equivalent to the first line of (3.16). Taking all the above into account, the expressions for the remaining flux components $f, F^1, F^7$ are obtained by straightforward manipulations of equations (D.4, D.5, D.6), respectively.

E. Spinor vs four-form

In this section we prove the equivalence of the two equations in (3.15). One needs to show that the existence of the self-dual four-form $\Phi$ is equivalent to the existence of the chiral spinor $\eta$ (see e.g. [23]). The two equations in (3.15) are then essentially equivalent to the statement that $\Phi, \eta$ are acted upon by the Levi-Civita, the (associated) spin connection respectively, and that they are both $\text{Spin}(7)$ singlets. More explicitly,

$(\Longrightarrow)$: Let us expand
\[
\nabla_m \eta = A_m \eta + B_{m,pq} \gamma^{pq} \eta ,
\]
where without lost of generality, as can be seen from the first line of equation (B.2), $B_{m,pq}$ can be taken to satisfy
\[
B_{m,pq} = (P^T)^{rs}_{pq} B_{m,rs} .
\]
From (E.2) we can see immediately that
\[
4B_{[m,pq]} = B_{i[jm} \Phi^{ij}_{pq]} - \Phi_{mpq}^j B^i_{,ij}
\]
\[
B_{i,jk} \Phi^{ij}_{m} = -6B^i_{,im} ,
\]
from which it follows that
\[
B_{m,pq} \gamma^{pq} \eta = 6B_{[m,pq]} \gamma^{pq} \eta + 4B_{,pq}^m \gamma^m \eta .
\]

Moreover, the fact that $\eta$ has unit norm implies $A_m = 0$. On the other hand, it follows from the first line in (3.14) and (E.1) that
\[
\omega^1_m = -\frac{8}{7} B^i_{,im} \quad (E.6)
\]
\[
\omega^2_{mpq} = 6(B_{[m, pq]} + \frac{1}{i} \Phi_{mpq} B^i_{,ij}) \quad (E.7)
\]
Taking (E.4) into account, we can see that the right-hand side of (E.7) transforms in the 48 of Spin(7), as of course it should. Collecting all the above, the second line of equation (3.15) follows.

$(\Leftarrow)$: It can be shown that the four-form $\Phi$ satisfies the following useful identity \[37\]
\[
\varepsilon_{mpqrs}^{ijk} = \frac{1}{24} \Phi_{mpqrs} \Phi_{ijk} + \frac{3}{28} \Phi_{[mp} [ij} \Phi_{kl]_{pq]} + \frac{2}{21} \Phi_{[mpq} \Phi_{ijkl]}^{jk} \quad (E.8)
\]
Moreover, any $S_{mp}$ in the 48 of Spin(7) satisfies
\[
S_{mp} = \frac{3}{2} \Phi_{mp} \Phi_{ij} S_{ij} \quad (E.9)
\]
Using (E.8, E.9), we can see that
\[
\varepsilon_{mpqrs}^{ijk} \omega_{ijk} = 60 \Phi_{[mpq} \omega_{rs]_{ij}} \quad (E.10)
\]
Contracting the second line of (3.13) with $\eta_{pqrs}$ and using (E.10, 3.14), the first line of equation (3.13) follows.

F. Generalized Spin(7) structures

In this appendix we include the details of the derivation of equation (4.8). Multiplying (3.7), (3.8) on the left by $\xi^+ \gamma_m$, $\xi^- \gamma_m$ respectively and subtracting, we obtain
\[
F_{mijk} \hat{\Psi}_{ijk} = 36 \Psi^{-} \partial_m \Delta - 12 \Psi^{+} f_m + 72 m \Psi_m \quad (F.1)
\]
Multiplying (3.3), (3.6) on the left by $\xi^+$, $\xi^-$ respectively and adding/subtracting, taking (F.1) into account, we obtain
\[
0 = \partial_m \Psi^{+} \quad (F.2)
\]
Multiplying (3.7), (3.8) on the left by $\xi^+ \gamma_{mpqrs} \xi^- \gamma_{mpqrs}$ respectively and adding/subtracting, we obtain
\[
\hat{\Psi}_{[mpq} F_{rs]_{ij}} = -6 \Psi^{+} \partial_s \Delta + 2 \Psi^{-} f_s + \hat{\Psi}_{[mpq} F_{rs]} \quad (F.3)
\]
Multiplying (3.5), (3.6) on the left by $\xi^+\gamma_{pqrs}$, $\xi^-\gamma_{pqrs}$ respectively and adding/subtracting, taking (F.3) into account as well as the identity
\[ \hat{\Psi}[mpqr]_{ijk}^{F,s} = -\frac{6}{\hat{\Psi}[m]_{(\star F)_{pqrs}}}, \] (F.4)
we obtain
\[ 0 = e^{-6\Delta} \partial_{[m}(e^{6\Delta} \Psi^+_{pqrs}) + F_{mpqr} \hat{\Psi}_s] \]
\[ 0 = e^{-9\Delta} \partial_{[m}(e^{9\Delta} \Psi^-_{pqrs}) + (\star F)_{mpqr} \hat{\Psi}_s] - \Psi^+_{[mpqr} F_s] + \frac{8}{3} m \hat{\Psi}_{mpqr} \]. (F.5)

Rescaling the metric $g_{mn} \rightarrow g'_{mn} := e^{-3\Delta} g_{mn}$ has the effect that the gamma matrices also get rescaled as: $\gamma^m \rightarrow e^{3\Delta/2} \gamma^m$. Passing to the bispinor notation in the rescaled metric $g'_{mn}$, equations (F.2, F.5) can be written succinctly as
\[ 0 = d\Psi^+ + F \wedge \hat{\Psi}^- \]
\[ 0 = e^{-3\Delta} d(e^{3\Delta} \Psi^-) + \star F \wedge \hat{\Psi}^- - f \wedge \Psi^+ + 4m \hat{\Psi}^- , \] (F.6)
where
\[ \hat{\Psi}^- := \frac{1}{2}(\hat{\Psi} - \star \hat{\Psi}) = \frac{1}{8} P_+ \left\{ \frac{1}{3!} \hat{\Psi}_{m_1 \ldots m_3} \gamma_{m_1 \ldots m_3} + \frac{1}{7!} \hat{\Psi}_{m_1 \ldots m_7} \gamma_{m_1 \ldots m_7} \right\} . \] (F.7)

We also define
\[ \hat{\Psi}^+ := \frac{1}{2}(\hat{\Psi} + \star \hat{\Psi}) = \frac{1}{8} P_+ \left\{ \frac{1}{3!} \hat{\Psi}_{m_1 \ldots m_3} \gamma_{m_1 \ldots m_3} + \frac{1}{7!} \hat{\Psi}_{m_1 \ldots m_7} \gamma_{m_1 \ldots m_7} \right\} . \] (F.8)

Multiplying (3.7), (3.8) on the left by $\xi^-\gamma_{mp}$, $\xi^+\gamma_{mp}$ respectively and adding, we obtain
\[ \frac{1}{12} F_{[m}^{ijk} \Psi^+_{p] ijk} + \frac{1}{2} f_i \Psi^+_m = -3 \hat{\Psi}_m \partial_p \Delta . \] (F.9)

Multiplying (3.5), (3.6) on the left by $\xi^-\gamma_{pq}$, $\xi^+\gamma_{pq}$ respectively and adding, taking (F.9) into account, we obtain
\[ 0 = \partial_{[m}(e^{3\Delta} \hat{\Psi}^+_{pq}) . \] (F.10)

Multiplying (3.7), (3.8) on the left by $\xi^-\gamma_{mpqr}$, $\xi^+\gamma_{mpqr}$ respectively and subtracting, we obtain
\[ \frac{3}{4} \hat{\Psi}^-_{[mp} i F_{qr]ij} + \frac{1}{2} \Psi^-_{mpqr} F_i = -6 \hat{\Psi}_{[mpq} \partial_r] \Delta + \frac{1}{4} (\star F)_{mpqr} \Psi^+ + \frac{1}{4} F_{mpqr} \Psi^- + 3m \Psi^+_{mpqr} . \] (F.11)

Multiplying (3.5), (3.6) on the left by $\xi^-\gamma_{pq}$, $\xi^+\gamma_{pq}$ respectively and adding, taking (F.11) into account as well as the identity
\[ \frac{1}{24} \Phi^\pm_{mpqr} n_1 \ldots n_4 F_{n_1 \ldots n_4} = \pm \Phi^\pm (\star F)_{mpqr} \hat{\Phi}^\pm \hat{\Phi}^\pm . \] (F.12)
we obtain
\[ 0 = e^{-6\Delta} \partial_{[m}(e^{6\Delta} \hat{\Psi}^-_{pq}) + \frac{1}{4} (\star F)_{mpqr} \Psi^+ - \frac{1}{4} F_{mpqr} \Psi^- + m \Psi^+_{mpqr} . \] (F.13)
Multiplying (3.7), (3.8) on the left by $\xi^+\gamma_{mpqrst}$, $\xi^-\gamma_{mpqrst}$ respectively and subtracting, we obtain
\[ 5\Psi^+_{[mpq}F_{rst]i} + \frac{1}{2} \Psi^+_{mpqrst} f_i = -9\Psi^-_{[mpqrs}\partial_i\Delta + \frac{1}{4} \Psi^+_{[mpqrs}ijk F_{tij} . \] (F.14)

Multiplying (3.5), (3.6) on the left by $\xi^+\gamma_{pqrst}$, $\xi^-\gamma_{pqrst}$ respectively and adding, taking (F.14) into account as well as the identity
\[ 0 = \Psi^\pm_{mpqrs} \partial_t \Delta + 4\Psi^\pm_{mpqrst} i f_i = -9\Psi^-_{mpqrs} \partial_t \Delta + 4\Psi^+_{mpqrst} i f_i . \] (F.15)

we obtain
\[ 0 = \partial_{\Delta}(e^{9\Delta}\Psi^-_{pqrst}) . \] (F.16)

Multiplying (3.7), (3.8) on the left by $\xi^+\gamma_{mpqrstuv}$, $\xi^-\gamma_{mpqrstuv}$ respectively and subtracting, we obtain
\[ 12\Psi^+_{mpqrstuv} \partial_i \Delta = \frac{35}{2} \Psi^-_{mpqrstuv} + 3m\Psi^+_{mpqrstuv} \] (F.17)

Multiplying (3.5), (3.6) on the left by $\xi^+\gamma_{pqstuv}$, $\xi^-\gamma_{pqstuv}$ respectively and subtracting, taking (F.17) into account, we obtain
\[ 0 = \partial_{\Delta}(e^{12\Delta}\Psi^-_{pqstuv}) + m\Psi^+_{mpqrstuv} \] (F.18)

Passing to the bispinor notation for the rescaled metric, taking into account the identity
\[ (\star F)_{[mpq} \Psi_{rstuv]}^+ - F_{[mpqr} \Psi_{stuv]}^- = 0, \] (F.19)

equations (F.10, F.13, F.16, F.18) can be written succinctly as
\[ 0 = e^{-3\Delta/2} d(e^{3\Delta/2}\Psi^-) \]
\[ 0 = e^{-3\Delta/2} d(e^{3\Delta/2}\Psi^+) + 2(\star F \wedge \Psi^+ - F \wedge \Psi^-) + 8m\Psi^+ \] (F.20)

It is easy to see that the integrability of (F.6, F.20) follows from the equations-of-motion and Bianchi identities. The ‘asymmetry’ between $\Psi^\pm$ in equation (F.6) disappears in the massless limit for constant warp factor and in the absence of fluxes along the noncompact spacetime directions; i.e. for $\Delta =$constant, $m$, $f = 0$. In this case we have:
\[ 0 = d\Psi^+ + F \wedge \Psi^- \]
\[ 0 = d\Psi^- + \star F \wedge \Psi^- \]
\[ 0 = d\Psi^- \]
\[ 0 = d\Psi^+ + 2(\star F \wedge \Psi^+ - F \wedge \Psi^-) \] (F.21)

The integrability of the above equations follows from the equations-of-motion and Bianchi identities, which now read $dF, d\star F = 0$. Note, however, that setting $m = 0$ excludes any solutions with nonzero fluxes if $X$ is smooth and compact, as was already noted in section 3.
