Abstract

This paper presents a hierarchical Bayesian model to reconstruct sparse images when the observations are obtained from linear transformations and corrupted by an additive white Gaussian noise. Our hierarchical Bayes model is well suited to such naturally sparse image applications as it seamlessly accounts for properties such as sparsity and positivity of the image via appropriate Bayes priors. We propose a prior that is based on a weighted mixture of a positive exponential distribution and a mass at zero. The prior has hyperparameters that are tuned automatically by marginalization over the hierarchical Bayesian model. To overcome the complexity of the posterior distribution, a Gibbs sampling strategy is proposed. The Gibbs samples can be used to estimate the image to be recovered, e.g. by maximizing the estimated posterior distribution. In our fully Bayesian approach the posteriors of all the parameters are available. Thus our algorithm provides more information than other previously proposed sparse reconstruction methods that only give a point estimate. The performance of the proposed hierarchical Bayesian sparse reconstruction method is illustrated on synthetic data and real data collected from a tobacco virus sample using a prototype MRFM instrument.

I. INTRODUCTION

For several decades, image deconvolution has been of increasing interest [2], [47]. Image deconvolution is a method for reconstructing images from observations provided by optical or other devices and may include denoising, deblurring or restoration. The applications are numerous including astronomy [49], medical imagery [48], remote sensing [41] and photography [55]. More recently, a new imaging technology, called Magnetic Resonance Force Microscopy (MRFM), has been developed (see [38] and [29] for reviews). This non-destructive method allows one to improve the detection sensitivity of standard magnetic resonance imaging (MRI) [46]. Three dimensional MRI at 4nm spatial resolution has recently been achieved by the IBM MRFM prototype for imaging the proton density of a tobacco virus [8]. Because of its potential atomic-level resolution\(^1\), the 2-dimensional or 3-dimensional images resulting from this technology are naturally sparse in the standard pixel basis. Indeed, as the observed objects are molecules, most of the image is empty space. In this paper, a hierarchical Bayesian model is proposed to perform reconstruction of such images.

Sparse signal and image deconvolution has motivated research in many scientific applications including: spectral analysis in astronomy [4]; seismic signal analysis in geophysics [7], [45]; and deconvolution of ultrasonic B-scans [39]. We propose here a hierarchical Bayesian model that is based on selecting an appropriate prior distribution for the unknown image and other unknown parameters. The image prior is composed of a weighted mixture of a standard exponential distribution and a mass at zero. When the non-zero part of this prior is chosen to be a centered normal distribution, this prior reduces to a Bernoulli-Gaussian process. This distribution has been widely used in the literature to build Bayesian estimators for sparse deconvolution problems (see [5], [16], [24], [28], [33] or more recently [3] and [17]). However, choosing a distribution with heavier tail may improve the sparsity inducement of the prior. Combining a Laplacian distribution with an atom at zero results in the so-called LAZE prior. This distribution has been used in [27] to solve a general denoising problem in a non-Bayesian quasi-maximum likelihood estimation framework. In [52], [54], this prior has also been used for sparse reconstruction of noisy images, including MRFM. The principal weakness of these previous approaches is the sensitivity to hyperparameters that determine the prior distribution, e.g. the LAZE mixture coefficient and the weighting of the prior vs the

\(^1\)Note that the current state of art of the MRFM technology allows one to acquire images with nanoscale resolution. However, atomic-level resolution might be obtained in the future.
likelihood function. The hierarchical Bayesian approach proposed in this paper circumvents these difficulties. Specifically, a new prior composed of a mass at zero and a single-sided exponential distribution is introduced, which accounts for positivity and sparsity of the pixels in the image. Conjugate priors on the hyperparameters of the image prior are introduced. It is this step that makes our approach hierarchical Bayesian. The full Bayesian posterior can then be derived from samples generated by Markov chain Monte Carlo (MCMC) methods [44].

The estimation of hyperparameters involved in the prior distribution described above is the most difficult task and poor estimation leads to instability. Empirical Bayes (EB) and Stein unbiased risk (SURE) solutions were proposed in [52], [54] to deal with this issue. However, instability was observed especially at higher signal-to-noise ratios (SNR). In the Bayesian estimation framework, two approaches are available to estimate these hyperparameters. One approach couples MCMC methods to an expectation-maximization (EM) algorithm or to a stochastic EM algorithm [30], [32] to maximize a penalized likelihood function. The second approach defines non-informative prior distributions for the hyperparameters; introducing a second level of hierarchy into the Bayesian formulation. This latter fully Bayesian approach, adopted in this paper, has been successfully applied to signal segmentation [11], [14], [15] and semi-supervised unmixing of hyperspectral imagery [13].

Only a few papers have been published on reconstruction of images from MRFM data [6], [8], [56], [58]. In [21], several techniques based on linear filtering and maximum-likelihood principles were proposed that do not exploit image sparsity. More recently, Ting et al. has introduced sparsity penalized reconstruction methods for MRFM (see [54] or [53]). The reconstruction problem has been formulated as a decomposition into a deconvolution step and a denoising step, yielding an iterative thresholding framework. In [54] the hyperparameters are estimated using penalized log-likelihood criteria including the SURE approach [50]. Despite promising results, especially at low SNR, penalized likelihood approaches require iterative maximization algorithms that are often slow to converge and can get stuck on local maxima [10]. In contrast to [54], the fully Bayesian approach presented in this paper converges quickly and produces estimates of the entire posterior and not just the local maxima. Indeed, the hierarchical Bayesian formulation proposed here generates Bayes-optimal estimates of all image parameters, including the hyperparameters.

In this paper, the response of the MRFM imaging device is assumed to be known. While it may be possible to extend our methods to unknown point spread functions, e.g., along
the lines of [22], [23], the case of sparse blind deconvolution is outside of the scope of this paper.

This paper is organized as follows. The deconvolution problem is formulated in Section II. The hierarchical Bayesian model is described in Section III. Section IV presents a Gibbs sampler that allows one to generate samples distributed according to the posterior of interest. Simulation results, including extensive performance comparison, are presented in Section V. In Section VI we apply our hierarchical Bayesian method to reconstruction of a tobacco virus from real MRFM data. Our main conclusions are reported in Section VII.

II. PROBLEM FORMULATION

Let X denote a $l_1 \times \ldots \times l_n$ unknown $n$-dimensional pixelated image to be recovered (e.g. $n = 2$ or $n = 3$). Observed are a collection of $P$ projections $y = [y_1, \ldots, y_P]^T$ which are assumed to follow the model:

$$y = T(\kappa, X) + n,$$  (1)

where $T(\cdot, \cdot)$ stands for a bilinear function, $n$ is a $P \times 1$ dimension noise vector and $\kappa$ is the kernel that characterizes the response of the imaging device. In the right-hand side of (1), $n$ is an additive Gaussian noise sequence distributed according to $n \sim \mathcal{N}(0, \sigma^2 I_P)$, where the variance $\sigma^2$ is assumed to be unknown.

Note that in standard deblurring problems, the function $T(\cdot, \cdot)$ represents the standard $n$-dimensional convolution operator $\otimes$. In this case, the image $X$ can be vectorized yielding the unknown image $x \in \mathbb{R}^M$ with $M = P = l_1 l_2 \ldots l_n$. With this notation, Eq. (1) can be rewritten:

$$y = Hx + n \quad \text{or} \quad Y = \kappa \otimes X + N$$  (2)

where $y$ (resp. $n$) stands for the vectorized version of $Y$ (resp. $N$) and $H$ is an $P \times M$ matrix that describes convolution by the point spread function (psf) $\kappa$.

The problem addressed in the following sections consists of estimating $x$ and $\sigma^2$ under sparsity and positivity constraints on $x$ given the observations $y$, the psf $\kappa$ and the bilinear function$^2$ $T(\cdot, \cdot)$.

$^2$In the following, for sake of conciseness, the same notation $T(\cdot, \cdot)$ will be adopted for the bilinear operations used on $n$-dimensional images $X$ and used on $M \times 1$ vectorized images $x$.

III. HIERARCHICAL BAYESIAN MODEL

A. Likelihood function

The observation model defined in (1) and the Gaussian properties of the noise sequence \( n \) yield:

\[
f(y|x, \sigma^2) = \left(\frac{1}{2\pi\sigma^2}\right)^{\frac{p}{2}} \exp\left(-\frac{\|y - T(\kappa, x)\|^2}{2\sigma^2}\right), \tag{3}
\]

where \( \|\cdot\| \) denotes the standard \( \ell_2 \) norm: \( \|x\|^2 = x^T x \).

B. Parameter prior distributions

The unknown parameter vector associated with the observation model defined in (1) is \( \theta = \{x, \sigma^2\} \). In this section, we introduce prior distributions for these two parameters; which are assumed to be independent.

1) Image prior: First consider the exponential distribution with shape parameter \( a > 0 \):

\[
g_a(x_i) = \frac{1}{a} \exp\left(-\frac{x_i}{a}\right) \mathbf{1}_{\mathbb{R}_+^*}(x_i), \tag{4}
\]

where \( \mathbf{1}_E(x) \) is the indicator function defined on \( E \):

\[
\mathbf{1}_E(x) = \begin{cases} 
1, & \text{if } x \in E, \\
0, & \text{otherwise.} 
\end{cases} \tag{5}
\]

Choosing \( g_a(\cdot) \) as prior distributions for \( x_i (i = 1, \ldots, M) \) leads to a maximum a posteriori (MAP) estimator of \( x \) that corresponds to a maximum \( \ell_1 \)-penalized likelihood estimate with a positivity constraint\(^3\). Indeed, assuming the component \( x_i (i = 1, \ldots, P) \) a priori independent allows one to write the full prior distribution for \( x = [x_1, \ldots, x_M]^T \):

\[
g_a(x) = \left(\frac{1}{a}\right)^M \exp\left(-\frac{\|x\|_1}{a}\right) \mathbf{1}_{\{x \succ 0\}}(x), \tag{6}
\]

where \( \{x \succ 0\} = \{x \in \mathbb{R}^M; x_i > 0, \forall i = 1, \ldots, M\} \) and \( \|\cdot\|_1 \) is the standard \( \ell_1 \) norm \( \|x\|_1 = \sum_i |x_i| \). This estimator has interesting sparseness properties for Bayesian estimation [1] and signal representation [20].

Coupling a standard probability density function (pdf) with an atom at zero is another alternative to encourage sparsity. This strategy has for instance been used for located event detection [28] such as spike train deconvolution [5], [7]. In order to increase the sparsity of

\(^3\)Note that a similar estimator using a Laplacian prior for \( x_i (i = 1, \ldots, M) \) was proposed in [51] for regression problems, referred to as the LASSO estimator, but without positivity constraint.
the prior, we propose to use the following distribution derived from $g_a(\cdot)$ as prior distribution for $x_i$:

$$f(x_i|w,a) = (1-w)\delta(x_i) + wg_a(x_i),$$

(7)

where $\delta(\cdot)$ is the Dirac function. This prior is similar to the LAZE distribution (Laplacian pdf and an atom at zero) introduced in [27] and used, for example, in [52], [54] for MRFM. However, since $g_a(x_i)$ is zero for $x_i \leq 0$, the proposed prior in (7) accounts for the positivity of the non-zero pixel values, a constraint that exists in many imaging modalities such as MRFM. By assuming the components $x_i$ to be a priori independent ($i = 1, \ldots, M$), the following prior distribution for $x$ is obtained:

$$f(x|w,a) = \prod_{i=1}^{M} [(1-w)\delta(x_i) + wg_a(x_i)].$$

(8)

Introducing the index subsets $I_0 = \{i; x_i = 0\}$ and $I_1 = \overline{I}_0 = \{i; x_i \neq 0\}$ allows one to rewrite the previous equation as follows:

$$f(x|w,a) = \left[(1-w)^{n_0} \prod_{i \in I_0} \delta(x_i) \right] \left[w^{n_1} \prod_{i \in I_1} g_a(x_i) \right],$$

(9)

with $n_\epsilon = \text{card}\{I_\epsilon\}$, $\epsilon \in \{0,1\}$. Note that $n_0 = M - n_1$ and $n_1 = \|x\|_0$ where $\|\cdot\|_0$ is the standard $\ell_0$ norm $\|x\|_0 = \# \{i; x_i \neq 0\}$.

2) Noise variance prior: A conjugate inverse-Gamma distribution with parameters $\nu_2$ and $\gamma_2$ is chosen as prior distribution for the noise variance [43, Appendix A]:

$$\sigma^2|\nu,\gamma \sim IG\left(\nu_2,\gamma_2\right).$$

(10)

In the following, the shape parameter $\nu$ will be fixed to $\nu = 2$ and the scale parameter $\gamma$ will be estimated as an hyperparameter (see [13], [14], [40]). Note that choosing the inverse-Gamma distribution $IG\left(\nu_2,\gamma_2\right)$ as a prior for $\sigma^2$ is equivalent to choosing a Gamma distribution $G\left(\frac{\nu}{2},\frac{\gamma}{2}\right)$ as a prior for $1/\sigma^2$.

C. Hyperparameter priors

The hyperparameter vector associated with the aforementioned prior distributions is $\Phi = \{a,\gamma, w\}$. Obviously, the accuracy of the proposed Bayesian model depends on the values of these hyperparameters. Sometimes prior knowledge may be available, e.g., the mean number of non-zero pixels in the image. In this case these parameters can be tuned manually to their true values. However, in many practical situations such prior information is not available and these hyperparameters must be estimated directly from the data. Priors for these hyperparameters, sometimes referred to as “hyperpriors” are given below.
1) **Hyperparameter \(a\):** A conjugate inverse-Gamma distribution is assumed for the scale parameter \(a\) of the distribution \(g_a(\cdot)\) of non-zero pixel intensities:

\[
a|\alpha \sim IG(\alpha_0, \alpha_1),
\]

with \(\alpha = [\alpha_0, \alpha_1]^T\). Similarly to [19], the fixed hyperparameters \(\alpha_0\) and \(\alpha_1\) have been chosen to obtain a vague prior: \(\alpha_0 = \alpha_1 = 10^{-10}\).

2) **Hyperparameter \(\gamma\):** A non-informative Jeffreys’ prior [25], [26] is assumed for the scale parameter of the inverse Gamma prior density on the noise variance \(\sigma^2\):

\[
f(\gamma) \propto \frac{1}{\gamma} I_{\mathbb{R}^+}(\gamma).
\]

The combination of the priors (10) and (12) yields the non-informative Jeffreys’ prior on \(\sigma^2\). Note that there is no difference between choosing a non-informative Jeffreys prior for \(\sigma^2\) and the proper hierarchical prior defined by (10) and (12). Indeed, integrating over the hyperparameter \(\gamma\) in the joint \(f(\sigma^2, \gamma)\) distribution yields:

\[
f(\sigma^2) = \int f(\sigma^2|\gamma) f(\gamma) d\gamma
\]

\[
\propto \left(\frac{1}{\sigma^2}\right)^2 \int \exp\left(-\frac{\gamma}{2\sigma^2}\right) d\gamma
\]

\[
\propto \frac{1}{\sigma^2}.
\]

However, in more complex noise models the hierarchical priors \(f(\sigma^2|\gamma)\) and \(f(\gamma)\) are not equivalent to such a simple prior on \(\sigma^2\). For example, as in [12], this pair of hierarchical priors is easily generalizable to conditionally Gaussian noise with spatial correlation and spatially varying signal-to-noise ratio.

3) **Hyperparameter \(w\):** A uniform distribution on the simplex \([0, 1]\) has been chosen as prior distribution for the mean proportion of non-zero pixels:

\[
w \sim U([0, 1]).
\]

This is the least informative prior on the image sparsity factor. Assuming that the individual hyperparameters are statistically independent the full hyperparameter prior distribution for \(\Phi\) can be expressed as:

\[
f(\Phi|\alpha) = f(w) f(\gamma) f(a)
\]

\[
\propto \frac{1}{\gamma a a_0 + 1} \exp\left(-\frac{\alpha_1}{a}\right)
\]

\[
\times I_{[0,1]}(w) I_{\mathbb{R}^+}(a) I_{\mathbb{R}^+}(\gamma),
\]
D. Posterior distribution

The posterior distribution of $\{ \theta, \Phi \}$ can be computed as follows:

$$f(\theta, \Phi | y, \alpha) \propto f(y | \theta) f(\theta | \Phi) f(\Phi | \alpha),$$

with

$$f(\theta | \Phi) = f(x | a, w) f(\sigma^2 | \gamma),$$

where $f(y | \theta)$ and $f(\Phi | \alpha)$ have been defined in (3) and (15). This hierarchical structure, represented on the directed acyclic graph (DAG) in Fig. 1, allows one to integrate out the parameter $\sigma^2$ and the hyperparameter vector $\Phi$ in (16) to obtain the posterior of the image given the measured data and the parameters $x$:

$$f(x | y, \alpha) \propto B(1 + n_1, 1 + n_0) \frac{\Gamma(n_1 + \alpha_0)}{\|x\|_1 + \alpha_1}^{n_1 + \alpha_0} 1_{\{x > 0\}}(x).$$

In (18), as defined in paragraph III-B.1, $n_1 = \|x\|_0$, $n_0 = M - \|x\|_0$ and $B(\cdot, \cdot)$ stands for the Beta function $B(u, v) = \Gamma(u) \Gamma(v) / \Gamma(u + v)$, where $\Gamma(\cdot)$ denotes the Gamma function.

The next section presents an appropriate Gibbs sampling strategy [44, Chap. 10] that allows one to generate an image sample distributed according to the posterior distribution $f(x | y, \alpha)$. 

---

**Fig. 1.** DAG for the parameter priors and hyperpriors (the fixed non-random hyperparameters appear in dashed boxes).
IV. A Gibbs sampling strategy
for sparse image reconstruction

In this section, we describe the Gibbs sampling strategy for generating samples \( \{x^{(t)}\}_{t=1,...} \) distributed according to the posterior distribution in (18). As simulating directly according to (18) is difficult, it is much more convenient to generate samples distributed according to the joint posterior \( f(x, \sigma^2, a, w|y, \alpha) \). This Gibbs sampler produces sequences \( \{x^{(t)}\}_{t=1,...}, \{\sigma^{2(t)}\}_{t=1,...}, \{a^{(t)}\}_{t=1,...}, \{w^{(t)}\}_{t=1,...} \) which are Markov chains with stationary distributions \( f(x|y, \alpha), f(\sigma^2|y, \alpha), f(a|y, \alpha) \) and \( f(w|y, \alpha) \), respectively [44, p. 345]. Then, the MAP estimator of the unknown image \( x \) will be computed by retaining among \( \mathcal{X} = \{x^{(t)}\}_{t=1,...} \) the generated sample that maximizes the posterior distribution in (18) [35, p. 165]:

\[
\hat{x}_{\text{MAP}} = \arg\max_{x \in \mathbb{R}_+^M} f(x|y) \\
\approx \arg\max_{x \in \mathcal{X}} f(x|y).
\]  

(19)

The main steps of this algorithm are given in subsections IV-A and IV-D (see also Algorithm 1 below).

---

**Algorithm 1:**

Gibbs sampling algorithm for sparse image reconstruction

- **Initialization:**
  - Sample parameter \( x^{(0)} \) from the pdf in (9),
  - Sample parameter \( \tilde{\sigma}^{2(0)} \) from the pdf in (10),
  - Set \( t \leftarrow 1 \),
- **Iterations:** for \( t = 1, 2, \ldots \), do
  1. Sample hyperparameter \( w^{(t)} \) from the pdf in (21),
  2. Sample hyperparameter \( a^{(t)} \) from the pdf in (22),
  3. For \( i = 1, \ldots, M \), sample parameter \( x_i^{(t)} \) from the pdf in (23),
  4. Sample parameter \( \tilde{\sigma}^{2(t)} \) from the pdf in (26),
  5. Set \( t \leftarrow t + 1 \).
A. Generation of samples according to $f(w|x)$

Using (9), the following result can be obtained:

$$f(w|x) \propto (1 - w)^{n_0} w^{n_1},$$

(20)

where $n_0$ and $n_1$ have been defined in paragraph III-B.1. Therefore, samples from $f(w|x)$ can be generated by simulating from an image dependent Beta distribution:

$$w \mid x \sim Be(1 + n_1, 1 + n_0).$$

(21)

B. Generation of samples according to $f(a|x, \alpha)$

The form of the joint posterior distribution (16) implies that samples of $a$ can be generated by simulating from an image dependent inverse-Gamma distribution:

$$a \mid x, \alpha \sim IG(\|x\|_0 + \alpha_0, \|x\|_1 + \alpha_1).$$

(22)

C. Generation of samples according to $f(x|w, a, \sigma^2, y)$

The LAZE-type prior (7) chosen for $x_i$ ($i = 1, \ldots, M$) yields a posterior distribution of $x$ that is not closed form. However, one can easily derive the posterior distribution of each pixel intensity $x_i$ ($i = 1, \ldots, M$) conditioned on the intensities of the rest of the image. Indeed straightforward computations (Appendix I) yield:

$$f(x_i \mid w, a, \sigma^2, x_{-i}, y) \propto (1 - w_i)\delta(x_i)$$

$$+ w_i \phi_+(x_i \mid \mu_i, \eta_i^2),$$

(23)

where $x_{-i}$ stands for the vector $x$ whose $i$th component has been removed and $\mu_i$ and $\eta_i^2$ are given in Appendix I. In (23), $\phi_+(\cdot, m, s^2)$ stands for the pdf of the truncated Gaussian distribution defined on $\mathbb{R}_+^*$ with hidden mean and variance parameters equal to $m$ and $s^2$, respectively:

$$\phi_+(x, m, s^2) = \frac{1}{C(m, s^2)} \exp \left[ -\frac{(x - m)^2}{2s^2} \right] 1_{\mathbb{R}_+^*}(x),$$

(24)

with

$$C(m, s^2) = \sqrt{\frac{\pi s^2}{2}} \left[ 1 + \text{erf} \left( \frac{m}{\sqrt{2s^2}} \right) \right].$$

(25)

The form in (23) specifies $x_i \mid w, a, \sigma^2, x_{-i}, y$ as a Bernoulli-truncated Gaussian variable with parameter $(w_i, \mu_i, \eta_i^2)$. Appendix III presents an algorithm that can be used to generate samples from this distribution. This algorithm generates samples distributed according to $f(x \mid w, \sigma^2, a, y)$ by successively updating the coordinates of $x$ using a sequence of $M$ Gibbs moves (requiring generation of Bernoulli-truncated Gaussian variables).
D. Generation of samples according to $f(\sigma^2|x, y)$

Samples are generated in the following way:

$$\sigma^2|x, y \sim IG\left(\frac{P}{2}, \frac{\|y - T(\kappa, x)\|^2}{2}\right).$$  \hspace{1cm} (26)

V. SIMULATION ON SYNTHETIC IMAGES

TABLE I
PARAMETERS USED TO COMPUTE THE MRFM PSF.

| Parameter Description            | Name | Value       |
|---------------------------------|------|-------------|
| Amplitude of external magnetic  | $B_{\text{ext}}$ | $9.4 \times 10^3$ G |
| field                           |      |             |
| Value of $B_{\text{mag}}$ in the | $B_{\text{res}}$ | $1.0 \times 10^4$ G |
| resonant slice                  |      |             |
| Radius of tip                   | $R_0$ | 4.0 nm      |

Fig. 2. Left: Psf of the MRFM tip. Right: unknown sparse image to be estimated.
A. Reconstruction of 2-dimensional image

In this subsection, a $32 \times 32$ synthetic image, depicted in Fig. 2 (right panel), is simulated using the prior in (9) with parameters $a = 1$ and $w = 0.02$. In Figs. 2 and 3, white pixels stands for zero intensity values. A general analytical derivation of the psf of the MRFM tip has been given in [34] and with further explanation in [54]. Following this model, we defined a $10 \times 10$ 2-dimensional convolution kernel, the psf represented in Fig. 2 (left panel), that corresponds to the physical parameters shown in Table I. The associated psf matrix $H$ introduced in (2) is of size $1024 \times 1024$. The observed measurements $y$, which are of size $P = 1024$ and depicted in Fig. 3 (top panel), are corrupted by an additive Gaussian noise with two different variances $\sigma^2 = 1.2 \times 10^{-1}$ and $\sigma^2 = 1.6 \times 10^{-3}$, corresponding to signal-to-noise ratios SNR = 2dB and SNR = 20dB, respectively.

1) Simulation results: The observations are processed by the proposed algorithm using $N_{MC} = 2000$ iterations of the Gibbs sampler with $N_{bi} = 300$ burn-in iterations. The computation time for completing 100 iterations of the proposed algorithm is 80s for an unoptimized MATLAB 2007b 32bit implementation on a 2.2GHz Intel Core 2, while 100 iterations of the Landweber and empirical Bayesian algorithms require 0.15s and 2s, respectively. The MAP image reconstruction computed using (19) is depicted in Fig. 3 (bottom panel) for the two levels of noise considered. Observe that the estimated image is very similar to the actual image, Fig. 2 (right panel), even at low SNR.

Moreover, as the proposed algorithm generates samples distributed according to the posterior distribution in (18), these samples can be used to compute the posterior distributions of each parameter. For illustration, the posterior distributions of the hyperparameters $a$ and $w$, as well as the noise variance $\sigma^2$, are shown in Fig. 4, 5 and 6. These estimated distributions are in good agreement with the ground truth values of these parameters, randomly drawn from the prior distribution.

In many applications, a measure of confidence that a given pixel or pixel region is non-zero is of interest. Our Bayesian approach can easily generate such measures of confidence in the form of posterior probabilities of the specified event, sometimes known as the Bayesian p-value. Following the strategy detailed in Appendix III, the proposed Gibbs sampler generates a collection of samples $\{x^{(t)}\}_{t=1,...,N_{MC}}$, distributed according the posterior Bernoulli-truncated Gaussian distribution in (23). This sampling requires the generation of indicator variables $z_i$ ($i = 1, \ldots, n$) that reflect the presence or the absence of non-zero pixel values. It is the
Fig. 3. Top, left (resp. right): noisy observations for SNR = 2dB (resp. 20dB). Bottom, left (resp. right): reconstructed image for SNR = 2dB (resp. 20dB).

Fig. 4. Posterior distribution of hyperparameter $a$ (left: SNR = 2dB, right: SNR = 20dB).
indicator variable $z_i$ that $x_i > 0$ that provides information about non-zero pixels in the image. Using the equivalences $\{z_i = 0\} \Leftrightarrow \{x_i = 0\}$ and $\{z_i = 1\} \Leftrightarrow \{x_i > 0\}$, the posterior probability $P[x_i > 0 | y, \alpha]$ can be easily obtained by averaging over the Gibbs samples of the binary variables $\{z_i^{(t)}\}_{t=N_{bi}+1, \ldots, N_{MC}}$. To illustrate, these probabilities are depicted in Fig. 7. In addition, these Gibbs samples can be used to compute the probability of having non-zero pixels in a given area of the image. The estimated posterior probability for the event that a non-zero pixel is present inside the small red rectangle in the figure is equal to 45% for the case of SNR = 2dB. Conversely, the posterior probability of having a non-zero pixel in the green box is 5%. For SNR = 20dB the MAP algorithm correctly detects the presence of a
pixel in this region. On the other hand, even though at SNR = 2dB the MAP reconstruction has not detected this pixel, we can be 45% confident of the presence of such a pixel in the red rectangular region on the left panel of Fig. (7).

![Fig. 7](image-url)

The posterior distributions of four different pixels are depicted in Fig. 8. These posteriors are consistent with the actual values of these pixels that are represented as dotted red lines in these figures. In particular, in all cases the actual values all lie within the 75% central quantile of the posterior distribution.

2) **Comparison of reconstruction performances:** Here we compare our proposed hierarchical Bayesian method to the sparse reconstruction methods of [52], [54]. The techniques proposed in [52], [54] are based on penalized likelihood EM algorithms that perform empirical estimation of the unknown hyperparameters. Therein, two empirical Bayesian estimators, denoted Emp-MAP-Lap and Emp-MAP-LAZE, based on a Laplacian or a LAZE prior respectively, were proposed. We also compare to the standard Landweber algorithm [31] that has been previously used to perform MRFM image reconstruction [8], [57]. These are compared to our hierarchical Bayesian MAP reconstruction algorithm, given in (19), and also to a minimum mean square error (MMSE) reconstruction algorithm extracted from the estimated full Bayes posterior (18). The MMSE estimator of the image $x$ is obtained by...
Fig. 8. Posterior distributions of the non-zero values of $x$ for 4 different pixel locations and for SNR = 20dB (actual pixel intensity values are depicted with dotted red lines).

The posterior distribution of the non-zero values of $x$ for 4 different pixel locations and for SNR = 20dB (actual pixel intensity values are depicted with dotted red lines).

Empirical averaging over the last $N_r = 1700$ samples of the Gibbs sampler according to:

$$\hat{x}_{\text{MMSE}} = E[x|y] \approx \frac{1}{N_r} \sum_{t=1}^{N_r} x^{(N_k+t)}.$$ 

As in [54] we compare the various reconstruction algorithms with respect to several performance criteria. Let $e = x - \hat{x}$ denote the reconstruction error when $\hat{x}$ is the estimator of the image $x$ to be recovered. These criteria are: the $\ell_0$, $\ell_1$ and $\ell_2$-norms of $e$, which measures the accuracy of the reconstruction, and the $\ell_0$-norm of the estimator $\hat{x}$, which measures its sparsity. As pointed out in [54], a human observer can usually not visually detect the presence of non-zero intensities if they are below a small threshold. Thus, a less strict measure$^4$ of

$^4$The introduced measure of sparsity is denoted $\| \cdot \|_A$. This is an abuse of notation since it is not a norm.
sparsity than the $\ell_0$-norm, which is denoted $\|\cdot\|_\delta$, is the number of reconstructed image pixels that are less than a given threshold $\delta$:

$$
\|\hat{x}\|_\delta = \sum_{i=1}^M 1_{\hat{x}_i < \delta},
$$

$$
\|e\|_\delta = \sum_{i=1}^M 1_{e_i < \delta}.
$$

(28)

It what follows, $\delta$ has been chosen as $\delta = 10^{-2} \|x\|_\infty$. To summarize, the following criteria have been computed for the image in paragraph V-A.1 for two levels of SNR: $\|e\|_0$, $\|e\|_\delta$, $\|e\|_1$, $\|e\|_2$, $\|\hat{x}\|_0$ and $\|\hat{x}\|_\delta$.

Table II shows the six performance measures for the five different algorithms studied. The proposed Bayesian methods (labeled “proposed MMSE” and “proposed MAP” in the table) outperform the other reconstruction algorithms in terms of $\ell_1$ or $\ell_2$-norms. Note that the MMSE estimation of the unknown image is a non sparse estimator in the $\ell_0$-norm sense. This is due to the very small but non-zero posterior probability of non-zero value at many pixels. The sparsity measure $\|\cdot\|_\delta$ indicates that most of the pixels are in fact very close to zero. The MAP reconstruction method seems to achieve the best balance between the sparsity of the solution and the minimization of the reconstruction error. Of course, by its very construction, the MMSE reconstruction will always have lower mean square error.

B. Reconstruction of undersampled 3-dimensional images

As discussed below in Section VI, the prototype IBM MRFM instrument [8] collects data projections as irregularly spaced, or undersampled, spatial samples. In this subsection, we indicate how the image reconstruction algorithm can be adapted to this undersampled scenario in 3D. We illustrate by a concrete example. First, a $24 \times 24 \times 6$ image is generated such that 4 pixels have non-zero values in each $z$ slice. The resulting data is depicted in Fig. 9 (top) and Fig. 10 (left). This image to be recovered is assumed to be convolved with a $5 \times 5 \times 3$ kernel that is represented in Fig. 10 (right). The resulting convolved image is depicted in Fig. 11 (left). However, the actual observed image is an undersampled version of this image. More precisely, the sampling rates are assumed to be $d_x = 2$, $d_y = 3$, $d_z = 1$, respectively, in the 3 dimensions. Consequently the observed 3D image, shown in Fig. 11, is of size $12 \times 8 \times 6$. Finally, an i.i.d. Gaussian noise with $\sigma = 0.02$ is added following the model in (1). Note that under these assumptions, the application $T(\cdot, \cdot)$ can be split into two standard operations.
TABLE II
RECONSTRUCTION PERFORMANCES FOR DIFFERENT SPARSE IMAGE RECONSTRUCTION ALGORITHMS.

| Method           | Error criterion   |
|------------------|-------------------|
|                  | $\|e\|_0$ | $\|e\|_\delta$ | $\|e\|_1$ | $\|e\|_2$ | $\|\hat{x}\|_0$ | $\|\hat{x}\|_\delta$ |
| SNR = 2dB        |               |               |               |               |               |               |

| Proposed MAP     | **19**    | 7        | 0.39         | 0.13        | **16**    | **16**   |

following the composition:

$$T(\kappa, X) = g_{d_e,d_y,d_z}(\kappa \otimes X),$$

(29)

where $g_{d_e,d_y,d_z}(\cdot)$ stands for the undersampling function.

The proposed hierarchical Bayesian algorithm is used to perform the sparse reconstruction with undersampled data. The number of Monte Carlo runs was fixed to $N_{MC} = 2000$ with $N_{bi} = 300$ burn-in iterations. Figure 9 shows the result of applying the proposed MAP estimator to the estimated posterior.

VI. APPLICATION ON REAL MRFM IMAGES

Here we illustrate the hierarchical Bayesian MAP reconstruction algorithm for real three dimensional MRFM data. The data is a set of MRFM projections of a sample of tobacco virus. Comprehensive details of both the experiment and the MRFM data acquisition protocol are given in [8] and the supplementary materials [9]. The observed sample consists of a
collection of Tobacco mosaic virus particles that constitute a whole viral segment in addition to viral fragments. The projections are computed from the measured proton distribution and
Fig. 11. Left: $24 \times 24 \times 6$ regularly sampled convolved image. Left: $12 \times 8 \times 6$ undersampled observed image.

the 3-dimensional psf following the protocol described in [8] and [9]. The resulting scan data are depicted in Figure 12 (top) for four different distances between the MRFM tip and the sample: $d = 24$nm, $d = 37$nm, $d = 50$nm and $d = 62$nm. Each of these x-y slices is of size $60 \times 32$ pixels.

These experimental data are undersampled, i.e. the spatial resolution of the MRFM tip, and therefore the psf function, is finer than the resolution of the observed slices. Consequently, these data have been deconvolved taking into account the oversampling rates defined by $d_x = 3$, $d_y = 2$ and $d_z = 3$ in the three directions. The MAP estimate of the unknown image is computed from $N_{MC} = 1000$ Gibbs samples of the proposed Bayesian algorithm initialized with the output of a single Landweber iteration. Several more iterations of the Landweber algorithm would produce the reconstructions reported in [8]. Three horizontal slices of the
Fig. 12. Top: experimental scan data where black (resp. white) pixel represents low (resp. high) density of spin (as in [8]). Middle: scan data reconstructed from the proposed hierarchical Bayesian algorithm. Bottom: scan data reconstructed from the Landweber algorithm.

estimated image\(^5\) are depicted in Figure 13. A 3-dimensional view of the estimated profile of the virus fragments is shown in Figure 14. The MMSE estimates of the parameters introduced in Section III are \(\hat{\sigma}^2_{\text{MMSE}} = 0.10\), \(\hat{a}_{\text{MMSE}} = 1.9 \times 10^{-12}\) and \(\hat{w}_{\text{MMSE}} = 1.4 \times 10^{-2}\). The image reconstructions produced by the Landweber and Bayesian MAP algorithms are shown in Fig. 12.

By forward projecting the estimated virus image through the point spread function one can visually evaluate the goodness of fit of the reconstruction to the raw measured data. This is depicted in Fig. 12. These figures are clearly in good agreement with the observed data (top). To evaluate the convergence speed, the reconstruction error is represented in Figure 15.

\(^5\)Note that most part of the estimated 3 dimensional image is empty space due to the very localized proton spin centers in the image.

as a function of the iterations for the proposed Bayesian and the Landweber algorithms. This shows that the convergence rate of our algorithm is significantly better than the Landweber
algorithm.

Fig. 15. Error of the reconstructions as functions of the iteration number for the proposed algorithm (continuous blue line) and Landweber algorithm (dotted red line).

VII. CONCLUSIONS

This paper presented a hierarchical Bayesian algorithm for deconvolving sparse positive images corrupted by additive Gaussian noise. A Bernoulli-truncated exponential distribution was proposed as a prior for the sparse image to be recovered. The unknown hyperparameters of the model were integrated out of the posterior distribution of the image, producing a full posterior distribution that can be used for estimation of the pixel values by extracting the mode (MAP) or the first moment (MMSE). An efficient Gibbs sampler was used to generate approximations to these estimates. The derived Bayesian estimators significantly outperformed several previously proposed sparse reconstruction algorithms. Our approach was implemented on real MRFM data to reconstruct a 3D image of a tobacco virus. Future work will include extension of the proposed method to other sparse bases, inclusion of uncertain point spread functions, and investigation of molecular priors. Future investigations might also include a comparison between the proposed MCMC approach and variational Bayes approaches.

APPENDIX I

DERIVATION OF THE CONDITIONAL
POSTERIOR DISTRIBUTION $f \left( x_i \mid w, a, \sigma^2, x_{-i}, y \right)$

The posterior distribution of each component $x_i$ ($i = 1, \ldots, M$) conditionally upon the others is linked to the likelihood function (3) and the prior distribution (7) via the Bayes’ formula:

$$f \left( x_i \mid w, a, \sigma^2, x_{-i}, y \right) \propto f \left( y \mid x, \sigma^2 \right) f \left( x_i \mid w, a \right).$$

(30)

This distribution can be easily derived by decomposing $x$ on the standard orthonormal basis

$$\mathbb{B} = \{ u_1, \ldots, u_M \},$$

(31)

where $u_i$ is the $i$th column of the $M \times M$ identity matrix. Indeed, let decompose $x$ as follows:

$$x = \tilde{x}_i + x_i u_i,$$

(32)

where $\tilde{x}_i$ is the vector $x$ whose $i$th element has been replaced by 0. Then the linear property of the operator $T(\kappa, \cdot)$ allows one to state:

$$T(\kappa, x) = T(\kappa, \tilde{x}_i) + x_i T(\kappa, u_i).$$

(33)

Consequently, (30) can be rewritten

$$f \left( x_i \mid w, a, \sigma^2, x_{-i}, y \right) \propto \exp \left( -\frac{\| e_i - x_i h_i \|^2}{2\sigma^2} \right) \times \left[ (1 - w)\delta(x_i) + \frac{w}{a} \exp \left( -\frac{x_i}{a} \right) I_{R^+}(x_i) \right],$$

(34)

where

$$\begin{cases} e_i = y - T(\kappa, \tilde{x}_i), \\ h_i = T(\kappa, u_i). \end{cases}$$

(35)

An efficient way to compute $e_i$ within the Gibbs sampler scheme is reported in Appendix II. Then, straightforward computations similar to those in [7] and [37, Annex B] yield to the following distribution:

$$f \left( x_i \mid w, a, \sigma^2, x_{-i}, y \right) \propto (1 - w_i)\delta(x_i)$$

$$+ w_i \phi_+ \left( x_i \mid \mu_i, \eta^2_i \right),$$

(36)

with

$$\begin{cases} \eta^2_i = \frac{\sigma^2}{\| h_i \|^2}, \\ \mu_i = \eta^2_i \left( \frac{h_i^T e_i}{\sigma^2} - \frac{1}{a} \right), \end{cases}$$

(37)

It can be noticed that, for deblurring applications, $h_i$ is also the $i$th column of the matrix $H$ introduced in (2).
and
\[
\begin{aligned}
    u_i = & \frac{w}{a} C \left( \mu_i, \eta_i^2 \right) \exp \left( \frac{\mu_i^2}{2\eta_i^2} \right), \\
    w_i = & \frac{u_i}{w_i + (1 - w)}.
\end{aligned}
\]

The distribution in (36) is a Bernoulli-truncated Gaussian distribution with hidden mean $\mu_i$ and hidden variance $\eta_i^2$.

**APPENDIX II**

**FAST RECURSIVE COMPUTATIONS FOR SIMULATING ACCORDING TO** $f(\mathbf{x}|w, a, \sigma^2, y)$

In the Gibbs sampling strategy presented in Section IV, the main computationally expensive task is the generation of samples distributed according to $f(x_i|w, a, \sigma^2, x_{-i}, y)$. Indeed, the evaluation of the hidden mean and hidden variance in (37) of the Bernoulli-truncated Gaussian distribution may be costly, especially when the bilinear application $T(\cdot, \cdot)$ is not easily computable. In this appendix, an appropriate recursive strategy is proposed to accelerate the Gibbs sampling by efficiently updating the coordinate $i$ of the vector $\mathbf{x}$ at iteration $t$ of the Gibbs sampler.

Let $\mathbf{x}^{(t,i-1)}$ denote the current Monte Carlo state of the unknown vectorized image $\mathbf{x}$ $(i = 1, \ldots, M)$:
\[
\mathbf{x}^{(t,i-1)} = \left[ x_1^{(t)}, \ldots, x_{i-1}^{(t)}, x_{i}^{(t-1)}, x_{i+1}^{(t-1)}, \ldots, x_{M}^{(t-1)} \right]^T. \tag{39}
\]
with, by definition, $\mathbf{x}^{(t,0)} = \mathbf{x}^{(t-1,M)}$. Updating $\mathbf{x}^{(t,i-1)}$ consists of drawing $x_i^{(t)}$ according to the Bernoulli-truncated Gaussian distribution $f\left(x_i|w, a, \sigma^2, \mathbf{x}_{-i}^{(t-1)}, y\right)$ in (23) with:
\[
\mathbf{x}^{(t,i-1)} = \left[ x_1^{(t)}, \ldots, x_{i-1}^{(t)}, x_{i+1}^{(t-1)}, \ldots, x_{M}^{(t-1)} \right]^T. \tag{40}
\]
The proposed strategy to simulate efficiently according to (23) is based on the following property.

**Property:** Given the quantity $T(\kappa, \mathbf{x}^{(0)})$ and the vectors $\{\mathbf{h}_i\}_{i=1,\ldots,M}$, simulating according to $f\left(x_i|w, a, \sigma^2, \mathbf{x}_{-i}^{(t,i)}, y\right)$ can be performed without evaluating the bilinear function $T(\cdot, \cdot)$.

**Proof:** Simulating according to (23) mainly requires to compute the vector $\mathbf{e}_i$ introduced by (35):
\[
\mathbf{e}_i = y - T(\kappa, \mathbf{x}_i^{(t,i-1)}), \tag{41}
\]
with
\[
x_i^{(t,i-1)} = \begin{bmatrix} x_1^{(t)}, \ldots, x_{i-1}^{(t)}, 0, x_{i+1}^{(t-1)}, \ldots, x_M^{(t-1)} \end{bmatrix}^T.
\] (42)

Moreover, by using the decomposition in (32) and by exploiting the linear property of \( T(\kappa, \cdot) \), the vector \( T(\kappa, x_i^{(t,i-1)}) \) in the right-hand side of (41) can be rewritten as:
\[
T(\kappa, x_i^{(t,i-1)}) = T(\kappa, x_i^{(t,i)}) - x_i^{(t-1)} h_i,
\] (43)

where \( h_i \) has been introduced in (35). Consequently, to prove the property, we have to demonstrate that the vector series \( \{ T(\kappa, x_i^{(t,k)}) \}_{k=1,\ldots,M} \) can be computed recursively without using \( T(\cdot, \cdot) \). Assume that \( T(\kappa, x_i^{(t,i)}) \) is available at this stage of the Gibbs sampling and that \( x_i^{(t)} \) has been drawn. The new Monte Carlo state is then:
\[
x_i^{(t,i)} = \begin{bmatrix} x_1^{(t)}, \ldots, x_{i-1}^{(t)}, x_i^{(t-1)}, \ldots, x_M^{(t-1)} \end{bmatrix}^T.
\] (44)

Similarly to (43), the vector \( T(\kappa, x_i^{(t,i)}) \) can be decomposed as follows:
\[
T(\kappa, x_i^{(t,i)}) = T(\kappa, x_i^{(t,i-1)}) + x_i^{(t)} h_i.
\] (45)

Therefore, combining (43) and (45) allow one to state:
\[
T(\kappa, x_i^{(t,i)}) = T(\kappa, x_i^{(t,i-1)}) + \left( x_i^{(t)} - x_i^{(t-1)} \right) h_i.
\]

The bilinear function \( T(\cdot, \cdot) \) only needs to be used at the very beginning of the Gibbs sampling algorithm to evaluate \( T(\kappa, x^{(0)}) \) and the vectors \( \{ h_i \}_{i=1,\ldots,M} \). The resulting simulation scheme corresponding to step 3 of Algorithm 1 is shown in Algorithm 2.

**APPENDIX III**

**SIMULATION ACCORDING TO A BERNOLLI-TRUNCATED GAUSSIAN DISTRIBUTION**

This appendix describes how we generate random variables distributed according to a Bernoulli-truncated Gaussian distribution with parameters \((w_i, \mu_i, \eta_i^2)\) whose pdf is:
\[
f(x_i \mid w_i, \mu_i, \eta_i^2) = (1 - w_i) \delta(x_i) + \frac{w_i}{C(\mu_i, \eta_i^2)} \exp \left[ -\frac{(x_i - \mu_i)^2}{2\eta_i^2} \right] \mathbf{1}_{R^*_+}(x_i)
\]
Algorithm 2:

Efficient simulation according to $f \left( x \mid w, a, \sigma^2, y \right)$

For $i = 1, \ldots, M$, update the $i$th coordinate of the vector $x^{(t,i-1)} = \left[ x_1^{(t)}, \ldots, x_{i-1}^{(t)}, x_i^{(t-1)}, x_{i+1}^{(t-1)}, \ldots, x_M^{(t-1)} \right]^T$ via the following steps:

1. compute $\|h_i\|^2$,
2. set $T \left( \kappa, \tilde{x}_i^{(t,i-1)} \right) = T \left( \kappa, x^{(t,i-1)} \right) - x_i^{(t-1)}h_i$,
3. set $e_i = x - T \left( \kappa, \tilde{x}_i^{(t,i-1)} \right)$,
4. compute $\mu_i, \eta_i^2$ and $w_i$ as defined in (37) and (38),
5. draw $x_i^{(t)}$ according to (23),
6. set $x^{(t,i)} = \left[ x_1^{(t)}, \ldots, x_{i-1}^{(t)}, x_i^{(t)}, x_{i+1}^{(t-1)}, \ldots, x_M^{(t-1)} \right]^T$,
7. set $T \left( \kappa, x^{(t,i)} \right) = T \left( \kappa, \tilde{x}_i^{(t,i-1)} \right) + x_i^{(t)}h_i$.

Algorithm 3:

Simulation according to a Bernoulli-truncated Gaussian distribution

1. generate $z_i$ according to $z_i \sim \text{Ber} \left( w_i \right)$,
2. set $x_i = 0$, if $z_i = 0$;
   \[ x_i \sim \mathcal{N}^+ \left( \mu_i, \eta_i^2 \right), \text{ if } z_i = 1. \]

where $C \left( \mu_i, \eta_i^2 \right)$ has been defined in (25). Monte Carlo draws from this density can be obtained by using an auxiliary binary variable $z_i$ following the strategy shown in Algorithm 3. This indicator variable takes the value 0 (resp. 1) if the pixel $x_i$ is zero (resp. non-zero).

In Algorithm 3, $\text{Ber} \left( \cdot \right)$ and $\mathcal{N}^+ \left( \cdot, \cdot \right)$ denote the Bernoulli and the positive truncated Gaussian distributions respectively. In step 2, samples distributed according to the truncated Gaussian distribution can be generated by using an appropriate accept-reject procedure with instrumental distributions [18], [36], [42].
ACKNOWLEDGEMENTS

The authors would like to thank Michael Ting (Seagate Technology) for providing the code to generate point spread functions of MRFM tip and Hichem Snoussi (University of Technology of Troyes) for interesting suggestions regarding this work. The authors are also very grateful to Dr. Daniel Rugar who provided the real data used in Section VI as well as a valuable feedback on this paper.
