A LIE THEORETICAL CONSTRUCTION OF A LANDAU–GINZBURG MODEL
WITHOUT PROJECTIVE MIRRORS

E. BALLICO, S. BARMEIER, E. GASPARIM, L. GRAMA, L. A. B. SAN MARTIN

ABSTRACT. We describe the Fukaya–Seidel category of a Landau–Ginzburg model LG(2) for the semisimple adjoint orbit of \( \mathfrak{sl}(2, \mathbb{C}) \). We prove that this category is equivalent to a full triangulated subcategory of the category of coherent sheaves on the second Hirzebruch surface. We show that no projective variety can be mirror to LG(2), and that this remains so after compactification.

1. INTRODUCTION

We describe the Fukaya–Seidel category corresponding to a Landau–Ginzburg model for the semisimple adjoint orbit of \( \mathfrak{sl}(2, \mathbb{C}) \). This is the simplest application of the following general result:

**Theorem.** [GGSM1, Thm. 3.1] Let \( \mathfrak{h} \) be the Cartan subalgebra of a complex semisimple Lie algebra. Given \( H_0 \in \mathfrak{h} \) and \( H \in \mathfrak{h}_R \) with \( H \) a regular element, the height function

\[
    f_H: \mathfrak{O}(H_0) \to \mathbb{C}
\]

defined by

\[
    f_H(x) = \langle H, x \rangle
\]

has a finite number (\( = |W|/|W_{H_0}| \)) of isolated singularities and gives \( \mathfrak{O}(H_0) \) the structure of a symplectic Lefschetz fibration.

Here \( \mathfrak{O}(H_0) \) denotes the adjoint orbit of \( H_0 \) viewed as a symplectic submanifold of \( \mathfrak{sl}(2, \mathbb{C}) \) with the symplectic form

\[
    \Omega = \operatorname{im} \mathcal{H},
\]

where \( \mathcal{H} \) is the Hermitian form on \( g \) defined by

\[
    \mathcal{H}(u, v) = \langle u, \tau v \rangle
\]

where \( \langle ., . \rangle \) is the Cartan–Killing form and \( \tau \) denotes any almost complex structure. Here we will take \( \tau \) to be multiplication by \( i \) coordinatewise.

In the language of mirror symmetry, \( f_H \) is called a superpotential.
Notation 1.1. Let us denote by LG(2) the Landau–Ginzburg model formed by the pair \((X, f_H)\) where \(X := \mathcal{O}(H_0)\) is the semisimple orbit of \(\mathfrak{sl}(2, \mathbb{C})\) for \(H_0 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}\) considered as a symplectic manifold with the symplectic form as in (1.1) and given the structure of a symplectic Lefschetz fibration by the superpotential \(f_H: X \to \mathbb{C}\) for the choice \(H = H_0\).

Remark 1.2. A similar example was studied by Khovanov and Seidel in [KhS] where they consider the Milnor fibration corresponding to the \(A_1\) singularity. Their methods are different from ours. The similarity resides in that, when resolving this singularity one obtains the cotangent bundle of \(\mathbb{P}^1\), which [KhS] consider with its canonical symplectic and complex structures. We stress that although our adjoint orbit \(\mathcal{O}(H_0)\) is diffeomorphic to \(\mathcal{T}^*\mathbb{P}^1\) the symplectic and complex structures we obtain are not equivalent to the canonical ones. Moreover, our approach via Lie theory is entirely new. In [BGGSM] we consider Landau–Ginzburg models for other adjoint orbits, and there the symplectic form is also taken as the imaginary part of the Hermitian form, which fits nicely with the structure of symplectic fibration.

We calculate the category of Lagrangian vanishing cycles for LG(2) and obtain:

**Theorem 3.1.** The Fukaya–Seidel category \(\text{Fuk}(\text{LG}(2))\) is generated by two Lagrangians \(L_0\) and \(L_1\) with morphisms:

\[
\text{Hom}(L_i, L_j) \cong \begin{cases} 
\mathbb{Z} \oplus \mathbb{Z}[-1] & i < j \\
\mathbb{Z} & i = j \\
0 & i > j 
\end{cases}
\]

and the products \(m_k\) all vanish except for \(m_2(\cdot, \text{id})\) and \(m_2(\text{id}, \cdot)\).

We then consider the question of finding a mirror to LG(2). That is, we look for an algebraic variety \(Y\) such that its derived category of coherent sheaves \(D^b(\text{Coh}\ Y)\) is equivalent to the Fukaya–Seidel category of LG(2). We first obtain a negative result.

**Theorem 4.1.** LG(2) has no projective mirrors.

This came to us as a surprise and brought along the question of whether the absence of projective mirrors might have resulted of the noncompactness of LG(2). We then compactified LG(2) to a new model \(\overline{\text{LG}(2)}\) where we extend the potential to a map with target \(\mathbb{P}^1\). However, for the compactified \(\overline{\text{LG}(2)}\), the absence of projective mirrors persists:

**Theorem 7.6.** \(\overline{\text{LG}(2)}\) has no projective mirrors.

The next best thing to do then is to find some projective variety \(Y\) such that a proper subcategory of \(D^b(\text{Coh}\ Y)\) is equivalent to \(\text{Fuk}(\text{LG}(2))\). We find that an appropriate choice is \(Y = F_2\), the second Hirzebruch surface.

**Theorem 8.1.** \(\text{Fuk}(\text{LG}(2))\) is equivalent to the full triangulated subcategory \(D^b(\text{Coh}\ Y) := \langle \mathcal{O}_{F_2}, \mathcal{O}_{F_2}(-E) \rangle\) of \(D^b(\text{Coh}\ F_2)\), where \(F_2\) is the second Hirzebruch surface and \(E\) is the divisor with self-intersection \(-2\).

We also describe these categories using quivers.

Acknowledgements. We are grateful to Patrick Clarke for pointing out a significant improvement to an earlier version of this work. We thank Ludmil Katzarkov, Denis Auroux, Lutz Hille, and Sukhendu Mehrotra for helpful suggestions and comments.

Part of this work was completed during a visit of L. Grama to Chile. We are thankful to the Vice Rectoría de Investigación and Desarrollo Tecnológico of the Universidad Católica del Norte whose support made this visit possible.
2. The structures of LG(2)

In this section we describe the Landau–Ginzburg model LG(2) = (\(\mathcal{O}(H_0), f_H\)) defined in 1.1 corresponding to the choices \(H_0 = H = (\begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}\) and symplectic form \(\Omega(A, B) = \text{im}(A, iB)\).

**Algebraic structure.** Set \(X := \mathcal{O}(H_0)\). Given \(A = (\begin{pmatrix} z & y \\ -y & -z \end{pmatrix} \in \mathfrak{sl}(2, \mathbb{C})\), if \(A \in \mathcal{O}(H_0)\), then its eigenvalues are \(\pm 1\), thus

\[(x - \lambda)(-x - \lambda) - yz = \det(A - \lambda I) = (\lambda + 1)(\lambda - 1) = \lambda^2 - 1.\]

Hence, \(X\) is the hypersurface in \(\mathbb{C}^3\) cut out by the equation

\[(2.1) \quad x^2 + yz - 1 = 0.\]

Since the derivatives of the polynomial \(p = x^2 + yz - 1\) vanish simultaneously only at the origin which is not in \(X\), it follows that \(X\) is a smooth complex surface. We know that in the case of \(\mathfrak{sl}(n, \mathbb{C})\), \(\langle A, B \rangle\) is a constant multiple of \(\text{tr}(AB)\). The choice of \(H_0 = (\begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}\) gives the height function

\[f_H(A) = \text{tr}(HA) = \text{tr}\left(\begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}\right)\begin{pmatrix} x & y \\ z & -x \end{pmatrix} = 2x.\]

So, we write the potential as

\[(2.2) \quad f_H: X \rightarrow \mathbb{C} \\
(x, y, z) \mapsto 2x.\]

**Smooth structure.** \(X\) is not compact. In further generality, let \(u\) be a real compact form of \(\mathfrak{sl}(n, \mathbb{C})\), then [GGSM2, Thm. 2.1] proves that the semisimple adjoint orbit is diffeomorphic to the cotangent bundle of the generalized flag variety \(\mathcal{O}(H_0) \cap iu\). For the orbit of \(\mathfrak{sl}(2, \mathbb{C})\) the flag variety is \(\mathbb{P}^1 \cong S^2\) and consequently we have the diffeomorphism \(X \cong T^*S^2\).

**Complex structure.** Let \(Z_2 = \text{Tot}_{\mathcal{O}_{\mathbb{P}^1}}(-2)\) with its canonical complex structure, and let \(r \in H^1(Z_2, TZ_2)\) be a non-zero cohomology class. Denote by \(Z_2(r)\) the complex deformation of \(Z_2\) corresponding to \(r\), see [BG, Sec. 4] for details. Observe that \(Z_2\) is not an affine variety (as the nontrivial first cohomology shows), hence the complex structure of \(X\) cannot be isomorphic to that of \(Z_2\). We claim that \(X\) is biholomorphic to \(Z_2(r)\). In fact, recall from [Ba, Sec. 9] that the algebra of global functions of \(Z_2(r)\) is given by

\[\mathbb{C}[x, y, z]/((x^2 + yz - 1).\]

So, the change of coordinates \((x, y) \mapsto (x + 1, -y)\) shows that \(Z_2(r) = X\) as affine varieties.

**Symplectic structure.** We have just shown that the diffeomorphism type of \(X\) is that of the cotangent bundle of a sphere. The next result shows that this sphere is a Lagrangian subvariety of \(X\).

**Lemma 2.1.** Consider the orbit \(X\) with the symplectic form \(\Omega\) defined in (1.1), then \(Y \subset X\) given by the equation \(p^2 + q^2 + r^2 = 1\) is a Lagrangian submanifold.

**Proof.** Let \(u\) be a real compact form of \(\mathfrak{sl}(2, \mathbb{C})\). Here \(u\) is the set of anti-Hermitian matrices with trace zero, thus \(iu\) is the set of Hermitian matrices with trace zero. Note that the submanifold \(Y\) can be described as the intersection \(Y = X \cap iu\). In fact, an arbitrary matrix \(S \in iu\) has the form

\[S = \begin{pmatrix} r & -p + iq \\ -p - iq & -r \end{pmatrix},\]

with \(p, q, r \in \mathbb{R}\). Since the orbit \(X\) consists of \(2 \times 2\) complex matrices whose entries satisfy \(x^2 + yz = 1\), we see that \(S \in X\) if and only if its entries satisfy \(p^2 + q^2 + r^2 = 1\).
The tangent space of $Y$ at $S$ is given by $T_{S}Y = \langle \{ S, A \} \mid A \in u \rangle$. Since $[i\{u,u\} \subset iu$ and $\text{tr}(MN)$ is real when $M, N \in iu$, we conclude that $\Omega(S, [S, A], [S, B]) = 0$ thus $Y$ is Lagrangian. 

\[ \text{Remark 2.2.} \quad \text{In greater generality, let } u \text{ be a real compact form of } g. \text{ The intersection } \mathcal{O}(H_{0}) \cap iu \text{ is a generalized flag variety, and a similar argument shows that such a generalized flag variety is Lagrangian for the symplectic form } \Omega. \]

3. THE FUKAYA–SEIDEL CATEGORY OF $\text{LG}(2)$

In this section we prove:

**Theorem 3.1.** The Fukaya–Seidel category of $\text{LG}(2)$ is generated by two Lagrangians $L_{0}$ and $L_{1}$ with morphisms:

\begin{equation}
\text{Hom}(L_{i}, L_{j}) \cong \begin{cases} 
Z \oplus Z[-1] & i < j \\
Z & i = j \\
0 & i > j
\end{cases}
\end{equation}

where we think of $Z$ as a complex concentrated in degree 0 and $Z[-1]$ as its shift, concentrated in degree 1, and the products $m_{k}$ all vanish except for $m_{2}(\cdot, \text{id})$ and $m_{2}(\text{id}, \cdot)$.

We will now describe the thimbles using branched covers. As described in §2 the orbit is $X = \{ x^{2} + yz = 1 \}$ together with the potential

\[ f_{H}: X \to \mathbb{C} \]

\[ (x, y, z) \mapsto 2x. \]

We need to describe the singular fibres. To find the critical points of $f_{H}|_{X}$ we use Lagrange multipliers, thus solving $\text{grad } f = \xi \text{grad } g$ with $g = 1$ which gives $(2, 0, 0) = (2x, z, y)$, where $g = g(x, y, x^{2}z) = x^{2} + yz$. We obtain the critical point $(x, y, z) = (1, 0, 0)$ with corresponding singular fibre $f_{H}^{-1}(1) = \{ yz = 0 \}$. The other critical point $(-1, 0, 0)$ may be obtained similarly.

For each regular value $c \in \mathbb{C}$ we have $f_{H}(\lambda) = 2x = c$ and a corresponding regular fibre over $c$, to simplify notation we parametrize the regular fibres by $\lambda := c/2$, so

\[ X_{\lambda} : = \{ yz = 1 - \lambda^{2} \}. \]

We first consider the cut given by $y = z$ where we need to analyse the two branches of the square root $y = \pm \sqrt{1 - \lambda^{2}}$. We get the two curves

\[ \lambda, \pm \sqrt{1 - \lambda^{2}}, \sqrt{1 - \lambda^{2}} \frac{\lambda - 1}{\lambda - 1} (1, 0, 0). \]

Using these curves we want to write down the thimbles, that is, for each $\lambda$ we wish to identify a circle in $X$ parametrized by $\gamma(t)$ with $\gamma(0) = \left( \lambda, \sqrt{1 - \lambda^{2}}, \sqrt{1 - \lambda^{2}} \right)$ and $\gamma(\pi) = \left( \lambda, -\sqrt{1 - \lambda^{2}}, -\sqrt{1 - \lambda^{2}} \right)$. For $0 \leq t \leq 2\pi$ we chose the thimble as:

\[ \alpha_{\lambda}(t) = \left( \lambda, e^{it} \sqrt{1 - \lambda^{2}}, e^{-it} \sqrt{1 - \lambda^{2}} \right). \]

Thus, $\alpha_{\lambda}(t) \to (1, 0, 0)$ as $\lambda \to 1$ (so $c \to 2$) and for a regular value $\lambda$ the curve $\gamma(t) := \alpha_{\lambda}(t)$ is a Lagrangian circle on the fibre $f_{H}^{-1}(2\lambda)$. We fix the regular value $0 \in \mathbb{C}$, and consider the straight line joining 0 to the critical value 2; this is our choice of a matching path. Then the family of Lagrangian circles $\alpha_{\lambda}(t)$ is fibred over this matching path and produces the Lagrangian thimble. With a similar analysis we can produce the Lefschetz thimble associated to the critical value $-2$.

Consider now the thimbles over the union of the two matching paths (line joining the two critical values $-2$ and 2), the circles fibering over them result in a sphere $Y$ inside the orbit $X$. As shown in 2.1 this sphere is Lagrangian in $X$.?
We will now describe the Fukaya–Seidel category associated to the Landau–Ginzburg model \( LG(X, f_{\text{ft}}) \). We first recall the definition.

**Definition 3.2.** [AKO1, Def. 3.1] The directed category of vanishing cycles \( \text{Lag}_{\infty}(f, \gamma) \) is an \( A_{\infty} \)-category (over a coefficient ring \( R \)) with \( r \) objects \( L_1, \ldots, L_r \) corresponding to the vanishing cycles (or more accurately, to the thimbles); the morphisms between the objects are given by

\[
\text{Hom}(L_i, L_j) = \begin{cases} 
CF^*(L_i, L_j, R) & \text{if } i < j \\
R \cdot \text{id} & \text{if } i = j \\
0 & \text{if } i > j 
\end{cases}
\]

and the differential \( m_1 \), composition \( m_2 \) and higher order products \( m_k \) are defined in terms of Lagrangian Floer homology inside the regular fibre \( X_0 \). See [AKO1] for further details.

We fix the regular value \( 0 \in \mathbb{C} \) of our LG model and consider the line segments \( \beta \) and \( \gamma \) that join \(-2 \) to \( 0 \) and \( 0 \) to \( 2 \), respectively. The objects of the Fukaya–Seidel category are the two Lagrangian thimbles \( L_0 := \alpha_{\beta(t)}(t) \) and \( L_1 := \alpha_{\gamma(t)}(t) \) (abusing notation we consider as \( L_0 \) and \( L_1 \) only the vanishing cycles in the regular fiber \( X_0 \); in our case, both circles \( S^1 \)).

To specify the products in the category, we need to describe \( CF^*(L_0, L_1) \). The regular fiber \( X_0 \) is homeomorphic to \( \mathbb{C}^1 \) and to the cylinder \( T^* S^1 \) via the map \( g: \mathbb{C}^1 \to T^* S^1 \) given by

\[
g(y) = \left( \frac{y}{|y|}, \ln |y| \right).
\]

In the regular fiber the vanishing cycles can be parametrized by the curve \((0, e^{it}, e^{-it}) \in X_0\) by setting \( \lambda = 0 \) in the expressions for the thimbles. Moreover, Lemma 2.1 implies that \( L_0 \) (and \( L_1 \)) is Lagrangian in \( X_0 \) and therefore by Weinstein's theorem we have that a tubular neighbourhood of \( L_0 \) is symplectomorphic to the cotangent bundle \( T^* S^1 \). In this situation the Floer homology is well known, see [Au] and [FOOO].

**Lemma 3.3.** \( HF^*(L_0, L_1) \approx H^*(S^1; \mathbb{R}) \).

We now fix a Morse function \( f: S^1 \to \mathbb{R} \) with exactly 2 critical points. A critical point of \( f \) with Morse index \( \text{ind}(p) \) defines a generator of degree \( \deg(p) = n - \text{ind}(p) \) in the Floer complex, where \( n \) is the dimension of the variety (in our case \( \dim S^1 = 1 \)). Since we have chosen \( f \) with exactly two critical points, a minimum \( x_0 \) and a maximum \( x_1 \), the Morse indices are 0 and 1, respectively. We obtain:

**Lemma 3.4.** There is a natural choice of grading such that \( \deg(x_0) = 0 \) and \( \deg(x_1) = 1 \).

Since the product \( m_1 \) in the Fukaya–Seidel category is the differential of Floer homology, using Lemma 3.3, we obtain the following description of the products \( m_i \):

**Lemma 3.5.** The products \( m_i \) for the Fukaya–Seidel category of \( LG(X) \) all vanish, except for the trivial products \( m_2(\text{id}, \cdot) \) and \( m_2(\cdot, \text{id}) \).

Here, the strict unit \( \text{id} \) equals \( x_0 \), and the result follows from strict-unitality and the degree considerations. Specifically, \( m_2(x_1, x_2) \) has degree 2 and so it is zero. Strict-unitality implies that the only possible non-zero products for \( i > 2 \) take only \( x_1 \) as argument, and \( m_i(x_1, \ldots, x_i) \) is zero because it has degree \( 2 - i < 0 \).

**Remark 3.6.** We compare with the mirror of \( \mathbb{P}^1 \). The Fukaya–Seidel category we just described is not isomorphic to the Fukaya–Seidel category of the mirror of \( \mathbb{P}^1 \) described in [AKO1]. Indeed, although the number of objects, morphisms and products of the \( A_{\infty} \) structures coincide, the gradings are different, hence the categories are not equivalent. We give a more detailed argument for this in the proof of Theorem 4.1.
4. Mirror candidates

We show that no projective variety is mirror to LG(2). In other words, suppose that we have a variety Y such that the bounded derived category \( D^b(\text{Coh} Y) \) coherent sheaves on \( Y \) is equivalent to our Fukaya–Seidel category of Theorem 3.1. Thus, we would need to have that \( D^b(\text{Coh} Y) \) is generated by some \( \mathcal{F}_0, \mathcal{F}_1 \in \text{Coh} Y \) satisfying:

\[
\text{Hom}(\mathcal{F}_i, \mathcal{F}_j) \equiv \begin{cases} 
\mathbb{C} \oplus \mathbb{C}[-1] & i < j \\
\mathbb{C} & i = j \\
0 & i > j
\end{cases}
\]

and with products \( m_k \) that vanish except for \( m_2(\cdot, \text{id}) \) and \( m_2(\text{id}, \cdot) \). We prove that any such variety \( Y \) cannot be projective. Hence:

**Theorem 4.1.** LG(2) has no projective mirrors.

*Proof.* We first argue that if \( \dim Y = n > 1 \) and \( Y \) is projective, then \( D^b(Y) \) cannot be generated by two simple objects \( \mathcal{L}_0, \mathcal{L}_1 \) such that \( \text{Hom}(\mathcal{L}_i, \mathcal{L}_j) = \mathbb{C} \) for \( i = 0, 1 \).

We will use the following facts. First, if \( \mathcal{C} \) is an abelian category, such as \( \text{Coh} X \) for any scheme \( X \), then the Grothendieck group \( K(\mathcal{C}) \) of \( \mathcal{C} \) is isomorphic to the Grothendieck group \( K(D^b(\mathcal{C})) \) of the bounded derived category of \( \mathcal{C} \). Recall that the Grothendieck group in either case is generated by the isomorphism classes of objects in the respective category. The relations in the first case are given by short exact sequences\(^1\), while in the latter by exact triangles, see [KaS, Ex. 1.27].

Second, if \( (\mathcal{A}, \mathcal{B}) \) is a semi-orthogonal decomposition of a triangulated category \( \mathcal{D} \), for example if \( \mathcal{D} = D^b(\text{Coh} X) \), then \( K(\mathcal{D}) = K(\mathcal{A}) \oplus K(\mathcal{B}) \). Note that the Grothendieck group of a triangulated category is defined in the obvious way: the generators are the isomorphism classes of objects, the relations come from exact triangles.

Finally, if \( D^b(\text{Coh} X) \) admits a semi-orthogonal decomposition by sheaves \( \mathcal{F}_1, \ldots, \mathcal{F}_m \) together with another factor \( \mathcal{L} \), that is,

\[
D^b(\text{Coh} X) = \langle \mathcal{F}_1, \mathcal{F}_2, \ldots, \mathcal{F}_m, \mathcal{L} \rangle,
\]

then

\[
G_0(X) := K(\text{Coh} X) = K(D^b(\text{Coh} X)) = K(\mathcal{F}_1) \oplus \cdots \oplus K(\mathcal{F}_m) \oplus K(\mathcal{L}),
\]

where by \( K(\mathcal{F}_i) \) we mean the Grothendieck group of the full triangulated category generated by \( \mathcal{F}_i \). Each of these is isomorphic to \( \mathbb{C} \) (we assume \( X \) is a scheme over the complex numbers, but this works over any field). Thus, \( \dim G_0(X) \geq m \), as claimed (or use [W, Prop. 2.1]). Since \( \dim G_0(X) \geq n + 1 \), we get \( n = 1 \).

Assume \( n = 1 \). If the normalization \( X' \) of \( X \) has geometric genus \( \geq 1 \), then [W, Prop. 4.6] gives that \( G_0(X) \) is not finitely generated. Now assume that \( X' = \mathbb{P}^1 \) and \( X \neq \mathbb{P}^1 \). In this case [W, Prop. 4.1] gives that a categorical resolution (in the sense of [Ku]) of \( D^b(\text{Coh} X) \) has a full exceptional collection, but the proof of [W, Prop. 4.1] gives that its length \( m \) is at least 3. Hence \( G_0(X) \neq \mathbb{Z}^2 \).

Next we exclude the case \( X = \mathbb{P}^1 \). Assume \( X = \mathbb{P}^1 \). \( \mathcal{L}_0 \) and \( \mathcal{L}_1 \) are simple objects of \( D^b(\mathbb{P}^1) \). Since \( \mathbb{P}^1 \) is a smooth curve, every coherent sheaf \( \mathcal{F} \) on \( \mathbb{P}^1 \) is a direct sum of a torsion sheaf \( \text{Tors}(\mathcal{F}) \) and a locally free sheaf \( \mathcal{F} / \text{Tors}(\mathcal{F}) \). Every locally free sheaf is isomorphic to a direct sum of line bundles. Every torsion sheaf is a direct sum of skyscraper sheaves \( \mathcal{S}_p, p \in \mathbb{P}^1 \). Hence the only simple coherent sheaves on \( \mathbb{P}^1 \) are the line bundles \( \mathcal{O}_{\mathbb{P}^1}(t), t \in \mathbb{Z} \), and the sheaves \( \mathcal{O}_p, p \in \mathbb{P}^1 \). No pair of them, not even after a shift \( \mathcal{L}_0[-1], \mathcal{L}_1[-j] \) may be of this form: if \( p, q \in \mathbb{P}^1 \) and \( p \neq q \), then \( \text{Hom}^1(\mathcal{O}_p, \mathcal{O}_q) = 0 \) for all \( i \), either \( \text{Hom}(\mathcal{L}, \mathcal{L}) = 0 \) or \( \text{Ext}^1(\mathcal{L}, \mathcal{L}) = 0 \) for any line bundles \( \mathcal{L}, \mathcal{L} \). Hence \( \dim \text{Ext}^1(\mathcal{O}_p, \mathcal{L}) = 1 \) for all \( p \in \mathbb{P}^1 \) and any line bundle \( \mathcal{L} \). Since \( \mathbb{P}^1 \) is a smooth curve,
[GKR, Prop. 6.3] gives that every simple element of $D^b(\mathbb{P}^1)$ is isomorphic to some $\mathcal{F}[-i]$ with $\mathcal{F}$ a simple coherent sheaf on $\mathbb{P}^1$.

We now proceed to the task of compactifying our LG model and verifying the effect of compactification on the Fukaya–Seidel category.

5. Compactification of the orbit

Recall that the orbit $X$ is an affine surface in $\mathbb{C}^3$, as described in (2.1). We will embed it into a projective surface $\overline{X}$, and see that the natural choice is $\overline{X} = \mathbb{P}^1 \times \mathbb{P}^1$. We compactify $X$ by homogenising equation (2.1). This produces the projective surface $\overline{X}$ cut out by $x^2 + yz - t^2 = 0$ in $\mathbb{P}^3$, that can be taken to the standard quadric equation by the change of coordinates $x \leftrightarrow x - t$ and $t \leftrightarrow x + t$, hence the surface is $\mathbb{P}^1 \times \mathbb{P}^1$. This compactification also works well from the symplectic point of view. Thus, we have:

**Theorem 5.1.** The semisimple adjoint orbit $(X, \Omega)$ of $\mathfrak{sl}(2, \mathbb{C})$ compactifies holomorphically and symplectically to $\mathbb{P}^1 \times \mathbb{P}^1$.

**Proof.** Recall from §2 that we may identify the complex structure of $X$ with that of a non-trivial deformation $Z_2(t)$ of $Z_2 = \text{Tot}(\mathcal{O}_{\mathbb{P}^1}(-2))$. In fact, the deformation of $Z_2$ extends to a deformation of its natural compactification, the second Hirzebruch surface $F_2$ obtained from $Z_2$ by adding a line at infinity, an irreducible divisor with self-intersection $+2$. It is well known that the complex surface $F_2$ deforms to the Hirzebruch surface $F_0 = \mathbb{P}^1 \times \mathbb{P}^1$. Identifying $Z_2$ as a subset of $F_2$, this deformation corresponds to a non-trivial element $t \in H^1(F_2, TF_2) = H^1(Z_2, TZ_2)$.

Under deformation of $F_2$, the added line at infinity decomposes into the sum $E + F$ of two divisors $E, F$ corresponding in the deformed surface $F_0 = \mathbb{P}^1 \times \mathbb{P}^1$ to the fibre and the zero section of $F_0$ (considered as the trivial $\mathbb{P}^1$-bundle over $\mathbb{P}^1$). The divisor $E + F$ is ample, and its complement is the affine variety $Z_2(t) = X$.

Thus, the complex structure of $X$ agrees with the one inherited from $F_0$, and similarly the metric on $X$ agrees with the Kähler metric inherited from $F_0$. These together imply that there exists a unique compatible symplectic structure on $X$ fitting the compactification to $F_0$. On the other hand, it is clear from definition 1.1 that the symplectic structure $\Omega$ on $X$ is compatible with the complex structure on $\mathfrak{sl}(2, \mathbb{C})$. Hence, the symplectic structure on $F_0$ restricts to $\Omega$ on $X$. □

Let us identify the compactified fibres of the LG model and the divisor at infinity. As seen in (2.2) the potential on the open orbit $X$ is $f_{GH}(A) = 2x$ and it has critical values $\pm 2$. Thus, 0 is a regular value, and we express the regular fibre (over zero) $X_0$ as the affine variety in $\{(y, z) \in \mathbb{C}^2\}$ cut out by the equation

$$yz - 1 = 0$$

since it must satisfy equation (2.1) and $x = 0$. As with the orbit, we homogenize this equation and embed the fibre into the corresponding projective variety $\overline{X}_0$ cut out by the equations $x = 0$ and $yz - t^2 = 0$ in $\mathbb{P}^3$. Here the complement of the orbit $\overline{X} \setminus i(X)$ in the compactification is obtained by making $t = 0$, thus $x^2 - yz = 0$ inside a projective plane $\mathbb{P}^2$, hence a conic curve, that is, a $\mathbb{P}^1$.

Next we need to compactify the potential. We will first extend the potential as a rational map over $\overline{X}$ and this rational map will then give rise to a holomorphic map on a compactification $\overline{\Gamma}$. We shall choose the symplectic form on $\Gamma$ such that it coincides with the original symplectic form on $X$ on an open neighborhood of its thimbles, thus keeping the Lagrangians we used to build the Fukaya category.
6. THE POTENTIAL VIEWED AS A RATIONAL MAP

Our goal now is to extend the potential to the compactification. We will make use of another incarnation of the orbit, namely the adjoint orbit of $e_1 \otimes e_1$ in $\mathbb{C}^2 \otimes (\mathbb{C}^2)^*$. The various incarnations of the orbits are described for the general case in [BGGSM, Sec. 4]. Here we will describe explicitly the isomorphism between two such incarnations for the case of $\mathfrak{sl}(2, \mathbb{C})$, then we will use the tensor product version of the orbit to show that the compactification naturally induces the Segre embedding into $\mathbb{P}^3$. Our extension of the potential to a rational map on $\mathbb{P}^1 \times \mathbb{P}^1$ factors through the Segre embedding. Note that the potential does not extend to a holomorphic map, not even if we change the target to $\mathbb{P}^1$. In [BGGSM, Sec. 6] it is shown how to extend the potential to a rational map for the cases when the orbit is diffeomorphic to $T^* \mathbb{P}^n$, all other cases remain open.

Let us first set up some notation. For this section we write $A \in \text{SL}(2, \mathbb{C})$ as

\begin{equation}
A = \begin{pmatrix} x & z \\ y & w \end{pmatrix},
\end{equation}

with $wx - yz = 1$, and fix the following basis for the Lie algebra $\mathfrak{sl}(2, \mathbb{C})$:

\begin{equation}
H = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \quad X_\alpha = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}, \quad X_{-\alpha} = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}.
\end{equation}

We consider the representation of the group $\rho : \text{SL}(2, \mathbb{C}) \rightarrow \text{GL}(\mathbb{C}^2)$ by left multiplication

\[\rho(A) \nu = A \nu\]

and the dual representation $\rho^* : \text{SL}(2, \mathbb{C}) \rightarrow \text{GL}(\mathbb{C}^2)^*$ given by

\[\rho^*(A) \epsilon = \epsilon \circ A^{-1}.
\]

We denote by $\theta := d\rho$ the corresponding representation of the Lie algebra $\mathfrak{sl}(2, \mathbb{C})$.

Let $\alpha$ be the positive root of $\mathfrak{sl}(2, \mathbb{C})$, that is, $\alpha = \lambda_1 - \lambda_2$, where $\lambda_i$ is the functional $\lambda_i(\text{diag}(x_1, x_2)) = x_i$, $i = 1, 2$. The fundamental weight for $\theta : \mathfrak{sl}(2, \mathbb{C}) \rightarrow \mathbb{C}^2$ is $\mu = \frac{1}{4} \alpha$, and the corresponding element in the Cartan subalgebra is

\[H_\mu = \frac{1}{8} \begin{pmatrix} 0 & 0 \\ 0 & -\frac{1}{2} \end{pmatrix}.
\]

Consider the canonical basis $\{e_1, e_2\}$ of $\mathbb{C}^2$. The weight spaces of the representation $\theta$ are: $V_1 = \text{span}(e_1)$ and $V_{-1} = \text{span}(e_2)$. Recall that $\theta(X_\alpha)$ maps $V_{-1}$ to $V_1$ and that $\theta(X_{-\alpha})$ maps $V_1$ to $V_{-1}$. Explicitly,

\[\theta(X_\alpha) \begin{pmatrix} a \\ b \end{pmatrix} = \begin{pmatrix} b \\ a \end{pmatrix}, \quad \theta(X_{-\alpha}) \begin{pmatrix} a \\ b \end{pmatrix} = \begin{pmatrix} 0 \\ a \end{pmatrix}.
\]

We set $\nu_0 = (1, 0) \in \mathbb{C}^2$ and $\epsilon_0 = (1, 0) \in (\mathbb{C}^2)^*$.

If $A \in \text{SL}(2, \mathbb{C})$ is written as in (6.1), then

\[B = \text{Ad}(A)H_\mu = AH_\mu A^{-1} = \begin{pmatrix} \frac{1}{2} (wx + yz) & -xz \\ yw & -\frac{1}{2} (wx + yz) \end{pmatrix}.
\]

The eigenvectors of $B$ are $(x, y)$ (associated to the eigenvalue $\frac{1}{2}$) and $(z, w)$ (associated to the eigenvalue $-\frac{1}{2}$).

**Lemma 6.1.** The adjoint action on the tensor product expression of the orbit can be interpreted as the Segre embedding.

**Proof.** We have the equality

\[A \cdot (\nu_0 \otimes \epsilon_0) = \rho(A) \nu_0 \otimes \rho^*(A) \epsilon_0,
\]

where

\[\rho(A) \nu_0 = \begin{pmatrix} x & z \\ y & w \end{pmatrix} \begin{pmatrix} 1 \\ 0 \end{pmatrix} = \begin{pmatrix} x \\ y \end{pmatrix}.
\]
and
\[
\rho^*(A)\varepsilon_0 = \varepsilon \circ \rho(A^{-1}) = \begin{pmatrix} 1 & 0 \\ -y & x \end{pmatrix} \begin{pmatrix} w \\ -z \end{pmatrix} = \begin{pmatrix} w \\ -z \end{pmatrix}.
\]
Therefore,
\[
(6.3) \quad A \cdot (v_0 \otimes \varepsilon_0) = \begin{pmatrix} xw \\ yw \end{pmatrix} - xz.
\]
Note that the eigenvalues of (6.3) are 0 (with associated eigenvector \((z, w)\)) and 1 (with associated eigenvector \((x, y)\)).

If we consider \((x, y)\) and \((z, w)\) as projective coordinates, then the action on the tensor product can be interpreted as the Segre embedding of \(\mathbb{P}^1 \times \mathbb{P}^1\) into \(\mathbb{P}^5\) (up to a sign), which is \([x : y], [z, w]) \mapsto [xz : xw : yz : yw]. \]

The next lemma provides a diffeomorphism between the orbit \(\text{SL}(2, \mathbb{C}) \cdot (v_0 \otimes \varepsilon_0)\) and the adjoint orbit \(\text{Ad}([\text{SL}(2, \mathbb{C})])H_\mu\).

**Lemma 6.2.** The orbit \(\text{SL}(2, \mathbb{C}) \cdot (v_0 \otimes \varepsilon_0)\) is diffeomorphic to the adjoint orbit \(\text{Ad}([\text{SL}(2, \mathbb{C})])H_\mu\).

**Proof.** The diffeomorphism between the orbits of \(\text{SL}(2, \mathbb{C})\) will be written using the moment map
\[
M(v \otimes \varepsilon)(Z) = \varepsilon(\theta(Z)v),
\]
where \(v \in \mathbb{C}^2, \varepsilon \in (\mathbb{C}^2)^*, Z \in \mathfrak{sl}(2, \mathbb{C})\). Let \(v = (x, y)\) and \(\varepsilon = (z, w)\). To describe \(M(v \otimes \varepsilon)\) in the base (6.2), we write:
\[
\begin{align*}
(M(v \otimes \varepsilon), H) & = \varepsilon(\theta(H)v) = \varepsilon(\frac{x}{2}x, \frac{1}{2}y) = \frac{1}{2}(wx + yz) \\
(M(v \otimes \varepsilon), X_a) & = \varepsilon(\theta(X_a)v) = \varepsilon(0, x) = -xz \\
(M(v \otimes \varepsilon), X_{-a}) & = \varepsilon(\theta(X_{-a})v) = \varepsilon(y, 0) = yw.
\end{align*}
\]
Therefore,
\[
(6.5) \quad M(v \otimes \varepsilon) = \begin{pmatrix} \frac{1}{2}(wx + yz) \\ yw \\ -\frac{1}{2}(wx + yz) \end{pmatrix} = \text{Ad}(A)H_\mu.
\]

**Theorem 6.3.** The rational map \(R_H: \overline{\mathcal{X}} = \mathbb{P}^1 \times \mathbb{P}^1 \to \mathbb{P}^1\) that extends the potential is \(R_H([x : y], [z : w]) = [xw + yz : xw - yz]\).

**Proof.** Choosing \(H = \text{Diag}(1, -1)\) we wish to extend the potential \(f_H\) to a rational map on the compactification
\[
(6.6) \quad R_H : \mathbb{P}^1 \times \mathbb{P}^1 \dashrightarrow \mathbb{P}^1.
\]
The rational map \(R_H\) that we are looking for is the map to \(\mathbb{P}^1\) associated to \(f_H\), that is, the rational map defined on the compactification that coincides with \(f_H\) in the open orbit. We claim that the extension is given by
\[
(6.7) \quad R_H(v \otimes \varepsilon) = \frac{\text{tr}((v \otimes \varepsilon)\theta(H))}{\text{tr}(v \otimes \varepsilon)} - \frac{wx + yz}{xw - yz}.
\]
Observe that:
- If \(v \otimes \varepsilon\) belongs to the adjoint orbit, then \(v \otimes \varepsilon\) has the form \(A \cdot v_0 \otimes \varepsilon_0\) for some \(A \in \text{SL}(2, \mathbb{C})\), that is, \(v \otimes \varepsilon \in \mathbb{C}^2 \otimes (\mathbb{C}^2)^*\) is a matrix of the form (6.3).
- The previous item implies that \(\text{tr}(v \otimes \varepsilon) = 1\) if \(v \otimes \varepsilon\) are in the orbit. Therefore \(R_H = f_H\) on the orbit.
- The poles of \(R_H\) are vectors whose coordinates satisfy \(xw = yz\). In other words, \((x, y)\) is a multiple of \((z, w)\). These are the pairs that are not in the adjoint orbit (formed by transversal lines).
Therefore, the map defined by formula (6.7) factors through the Segre embedding:
\[(x : y), [z : w]) \mapsto [xz : xw : yz : yw] \mapsto [xw + yz : xw - yz].\]
and coincides with \(f_H\) on the orbit, that is
\[(x : y), [z : w]) \mapsto [f_H : 1].\]

\(R_H\) is defined on points outside the orbit as
\[(x : y), [z : w]) \mapsto [2xw : 0],\]
except the points of the base locus \(P_1 = ([1 : 0], [1 : 0])\) and \(P_2 = ([0 : 1], [0 : 1])\), where the map is ill defined.

**Remark 6.4.** The rational map in Theorem 6.3 is defined outside the points \(P_1\) and \(P_2\).

Observe that these points are associated to the nilpotent matrices:
\[(6.9) ([1 : 0], [1 : 0]) = [1 : 0 : 0 : 0] = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}\]
and
\[(6.10) ([0 : 1], [0 : 1]) = [0 : 0 : 0 : 1] = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}.$

7. The compactified LG model

In Theorem 6.3 we extended the potential to a rational map \(R_H : \overline{X} = \mathbb{P}^1 \times \mathbb{P}^1 \to \mathbb{P}^1\) as
\[(x : y), [z : w]) \mapsto [xw + yz : xw - yz].\]
However, the map \(R_H\) is ill defined at \(P_1 = ([1 : 0], [1 : 0])\) and \(P_2 = ([0 : 1], [0 : 1])\). We wish to extend \(R_H\) to a holomorphic map and will do so by blowing up.

**Notation 7.1.** We take coordinates \((r, s)\) on the target \(\mathbb{P}^1\) and consider the graph \(\Gamma\) of \(R_H\) inside the product. We denote by \(\overline{\Gamma}\) the closure of \(\Gamma\) in \(\overline{X} \times \mathbb{P}^1\), hence \(\overline{\Gamma}\) is the surface cut out inside \(\mathbb{P}^1 \times \mathbb{P}^1 \times \mathbb{P}^1\) by
\[s(xw + yz) = r(xw - yz).\]

**Lemma 7.2.** \(\overline{\Gamma}\) is a holomorphic and symplectic compactification of \(X\).

**Proof.** By construction \(\overline{\Gamma}\) is a complex hypersurface of \(\mathbb{P}^1 \times \mathbb{P}^1 \times \mathbb{P}^1\) obtained by blowing up points on \(\overline{X}\). Hence it is clearly a holomorphic compactification of \(X\). However, pulling back the symplectic form of \(\overline{X}\) to \(\overline{\Gamma}\) by the blow-up map gives rise to a form that is degenerate on the exceptional set. We will now fix the degeneracy.

As shown in Theorem 5.1 the symplectic structure on \(\overline{X} = \mathbb{P}^1 \times \mathbb{P}^1\) is compatible with the one on \(X\). In Theorem 6.3 the potential was extended to a rational map \(R_H\) on \(\overline{X}\). We need to adapt the symplectic structure on \(\overline{\Gamma}\) to fit the situation. We claim that we have arrived at the situation of [Se, Sec. 3] where Seidel considers a holomorphic Morse function \(\sigma_0/\sigma_1\) defined on a smooth projective variety. In our case we have \(\sigma_0/\sigma_1 = xy + yz/xw - yz\) defined on \(\mathbb{P}^1 \times \mathbb{P}^1\). In this situation, we then look at the Lefschetz fibration of hypersurfaces
\[Y_z = \{ p \in X | \sigma_0(p)/\sigma_1(p) = z \}\]
for \(z \in \mathbb{P}^1 = C \cup \{\infty\}\). Note that here \(Y_{\infty}\) is smooth, as required by [Se]. Thus, we arrived directly at the second stage of his construction, where we already have a Lefschetz fibration together with a rational function on it (without having passed by a Lefschetz pencil beforehand). Following his method of patching in a correction to the symplectic form on a small neighborhood of the exceptional set we then arrive at the desired symplectic form. For our purposes it is important to take the neighborhood small enough so that it does not intersect the thimbles we had in \(X\), but this can be done since the points \(P_1\) and \(P_2\) where the \(R_H\) was ill defined are far from the thimbles of \(f_H\).
We will now use the projection to \([r : s]\) to extend the rational map \(R_H\) on \(\bar{X}\) to a holomorphic map \(F_H\) on \(\bar{T}\).

**Theorem 7.3.** Let \(\pi_3 : \mathbb{P}^1 \times \mathbb{P}^1 \times \mathbb{P}^1 \to \mathbb{P}^1\) be the projection onto the third factor and set \(F_H := \pi_3|_\Gamma\).

Then \(F_H\) is a holomorphic extension of \(f_H\).

**Proof.** In fact, for points in \(\Gamma\) we have that \(F_H([x : y], [z : w], [r : s]) = [x w + y z : x w - y z] = R_H([x : y], [z : w]).\)

Thus, \(F_H\) is an extension of \(R_H\) which in turn is an extension of \(f_H\) as shown in Theorem 6.3. \(\square\)

**Corollary 7.4.** The critical points of \(F_H\) coincide with the critical points of \(f_H\).

**Proof.** For a fixed value \([r : s] = [a : b]\) on the target, the fibre of \(F_H\) is cut out inside \(\mathbb{P}^1 \times \mathbb{P}^1\) by the polynomial equation

\[
\begin{align*}
&b(xw + yz) - a(xw - yz) = 0. \\
\end{align*}
\]

This describes a singular conic only in the cases when \(b = \pm a\), thus the only critical values of \(F_H\) are \([1 : 1]\) and \([1 : -1]\) with corresponding critical points \([1 : 0], [0 : 1]\) and \([0 : 1], [1 : 0]\). These in turn correspond to the critical points \(\pm H\) of \(f_H\). We conclude that extending \(f_H\) to \(F_H\) does not produce any extra critical points. \(\square\)

**Corollary 7.5.** The Fukaya–Seidel category of \(\overline{LG}(2)\) is the same as the one of \(LG(2)\).

**Proof.** Observe that in Lemma 7.2 chose the symplectic form on the compactification \(\bar{T}\) so that our original Lagrangian thimbles that generated the Fuk(\(LG(2)\)) remain Lagrangian in the compactification. Moreover, Corollary 7.4 shows that no new critical points are obtained when we extend the potential to the compactification. Therefore the Fukaya–Seidel category corresponding to the compactification is the same as the one described in Theorem 3.1. \(\square\)

In particular, using the results of §4 we conclude that this compact LG model \(\overline{LG}(2)\) does not have a projective mirror either. Hence we obtain:

**Theorem 7.6.** \(\overline{LG}(2)\) has no projective mirrors.

### 8. Mirror Category

Theorem 3.1 states that the Fukaya–Seidel category of \(LG(2)\) is generated by two Lagrangians \(L_0\) and \(L_1\) with the following morphisms

\[
\operatorname{Hom}(L_i, L_j) \cong \begin{cases} 
\mathbb{Z} & i < j \\
\mathbb{Z} & i = j \\
0 & i > j
\end{cases}
\]

Theorems 4.1 and 7.6 show that no projective variety may be the mirror of either \(LG(2)\) or else \(LG(2)\). However, we do have the following result, which in light of Lemma 9.1 below may be thought of as an instance of [O, Cor. 2.7].

**Theorem 8.1.** \(\operatorname{Fuk}(LG(2))\) is equivalent to the full triangulated subcategory \(D^b(\mathcal{O}I(2)) := \langle \mathcal{O}F_2, \mathcal{O}F_2(-E) \rangle\) of \(D^b(\mathcal{O}F_2)\), where \(F_2\) is the second Hirzebruch surface and \(E\) is the divisor with self-intersection \(-2\).
Proof. Let \( \{x_0 : x_1 : x_2\} \) and \( \{y_0 : y_1\} \) be the standard coordinates on \( \mathbb{P}^2 \) and \( \mathbb{P}^1 \). The second Hirzebruch surface is the hypersurface \( F_2 \subset \mathbb{P}^2 \times \mathbb{P}^1 \) cut out by the equation \( x_0 y_0^2 - x_1 y_1^2 \). The fibre \( F \) of the natural projection to \( \mathbb{P}^1 \) is a divisor with self-intersection \( 0 \); the exceptional fibre of the natural projection to \( \mathbb{P}^2 \) is a prime divisor \( E \) with self-intersection \(-2\). The line bundles associated to \( E, F \) generate the Picard group \( \text{Pic}(F_2) \) with relations

\[
E^2 = -2, \quad E \cdot F = 1, \quad F^2 = 0.
\]

Now consider the derived category generated by the line bundles \( \mathcal{O}_{F_2} \) and \( \mathcal{O}_{F_2}(\mathcal{E}) \); we denote this category by \( D^b(\text{LG}(2)) \), even though Theorem 4.1 shows that it is not the derived category of coherent sheaves on any projective variety \( \text{LG}(2) \).

The Hom- and Ext-groups of line bundles on \( F_2 \) may be calculated via toric geometry, giving

\[
\text{Hom}(\mathcal{O}, \mathcal{O}) \cong \mathbb{C}, \quad \text{Hom}(\mathcal{O}(\mathcal{E}), \mathcal{O}(\mathcal{E})) \cong \mathbb{C},
\]

all other Hom- and Ext-groups being zero.

Setting \( L_0 := \mathcal{O}_{F_2}(\mathcal{E}) \) and \( L_1 := \mathcal{O}_{F_2} \) we have in the derived category

\[
\text{Hom}(L_i, L_j) \cong \begin{cases} \mathbb{C} & i < j \\ \mathbb{C} & i = j \\ 0 & i > j \end{cases}
\]

in agreement with (3.1).

\[\square\]

9. Quivers

The pair \( (L_0, L_1) \) is not exceptional. However, following [HP] we may apply a "partial mutation" to find an exceptional pair of locally free sheaves with only nonvanishing Hom-groups, which generates \( D^b(\text{LG}(2)) \), as follows.

Let \( \mathcal{E} \) be a nontrivial extension of \( \mathcal{O}(\mathcal{E}) \) by \( \mathcal{O} \). We obtain a triangle

\[
\mathcal{O} \rightarrow \mathcal{E} \rightarrow \mathcal{O}(\mathcal{E}) \oplus \text{Ext}^1(\mathcal{O}(\mathcal{E}), \mathcal{O}) \rightarrow \mathcal{O}[1].
\]

By the results of [HP] (or by direct verification) we have:

**Lemma 9.1.** The pair \( (\mathcal{O}, \mathcal{E}) \) is exceptional and generates \( D^b(\text{LG}(2)) \). In particular, \( \mathcal{O} \oplus \mathcal{E} \) is a tilting bundle for \( D^b(\text{LG}(2)) \).

The fact that the collections \( (\mathcal{O}, \mathcal{O}(\mathcal{E})) \) and \( (\mathcal{O}, \mathcal{E}) \) both generate \( D^b(\text{LG}(2)) \) means that \( D^b(\text{LG}(2)) \) is equivalent to the derived categories of modules over the corresponding quivers. These equivalences come from writing the objects of each collection as vertices and a basis for the morphisms between these objects as arrows.

The collection \( (\mathcal{O}, \mathcal{O}(\mathcal{E})) \) gives rise to a graded quiver \( \widetilde{Q} \)

where the solid arrow is of degree 0 and the dotted arrow is of degree 1. \( \widetilde{Q} \) is a graded quiver without relations and the associated path algebra \( \widetilde{A} \) is a commutative graded algebra. Since \( \widetilde{Q} \) contains no composable arrows, all products except for multiplication by scalars vanish; cf. Lemma 3.5. We have an equivalence \( D^b(\text{mod-}\widetilde{A}) \cong D^b(\text{LG}(2)) \).

The exceptionality of the collection \( (\mathcal{O}, \mathcal{E}) \) means that we have an ordinary quiver
with relation $\beta \alpha = 0$. (The associated path algebra $A$ is an ordinary noncommutative algebra, i.e. a graded noncommutative algebra concentrated in degree 0.) Again, we obtain an equivalence $D^b(\text{mod-}A) \cong D^b(G,\Omega(2))$.
