We introduce two new lowest order methods, a mixed method, and a hybrid Discontinuous Galerkin (HDG) method, for the approximation of incompressible flows. Both methods use divergence-conforming linear Brezzi-Douglas-Marini space for approximating the velocity and the lowest order Raviart-Thomas space for approximating the vorticity. Our methods are based on the physically correct viscous stress tensor of the fluid, involving the symmetric gradient of velocity (rather than the gradient), provide exactly divergence-free discrete velocity solutions, and optimal error estimates that are also pressure robust. We explain how the methods are constructed using the minimal number of coupling degrees of freedom per facet. The stability analysis of both methods are based on a Korn-like inequality for vector finite elements with continuous normal component. Numerical examples illustrate the theoretical findings and offer comparisons of condition numbers between the two new methods.

**Keywords:** incompressible Stokes equations, mixed finite elements, pressure-robustness, Hybrid Discontinuous Galerkin methods, discrete Korn inequality

### 1. Introduction

In this work we introduce two new methods for the discretization of the steady incompressible Stokes equations in three space dimensions. Let $\Omega \subset \mathbb{R}^3$ be an open bounded domain with Lipschitz boundary $\partial \Omega$ that is split into the Dirichlet boundary $\Gamma_D$ and outflow boundary $\Gamma_N$. The Stokes system for the fluid velocity $u$ and the pressure $p$ is given by

\begin{align}
- \text{div}(\nu \varepsilon(u)) + \nabla p &= f \quad \text{in } \Omega, \quad (1a) \\
\text{div} u &= 0 \quad \text{in } \Omega, \quad (1b) \\
u &= 0 \quad \text{on } \Gamma_D, \quad (1c) \\
(-\nu \varepsilon(u) + pI)n &= 0 \quad \text{on } \Gamma_N, \quad (1d)
\end{align}

where $\varepsilon(u) := (\nabla u + \nabla u^T)/2$ is the symmetric gradient, $f : \Omega \to \mathbb{R}^3$ is an external body force, $\nu$ is twice the kinematic viscosity, $n$ is the outward unit normal vector and $I \in \mathbb{R}^{3 \times 3}$ is the identity matrix. We assume that both $\Gamma_D$ and $\Gamma_N$ have positive boundary measure, and any rigid displacement vanishing on $\Gamma_D$ vanishes everywhere in $\Omega$. (As usual, when $\Gamma_N$ is empty the pressure space must be adapted to obtain a unique pressure [16], but we omit this case for simplicity.) Next, define the *viscous stress tensor* [20] by $\sigma = \nu \varepsilon(u)$ and the *vorticity* by $\omega = \text{curl} u$. Using them, we can
rewrite the above system as

\begin{align}
\nu^{-1}\text{dev } \sigma - \nabla u + \kappa(\omega) &= 0 \quad \text{in } \Omega, \\
- \text{div } \sigma + \nabla p &= f \quad \text{in } \Omega, \\
\sigma - \sigma^T &= 0 \quad \text{in } \Omega, \\
\text{div } u &= 0 \quad \text{in } \Omega, \\
uu{u} &= 0 \quad \text{on } \Gamma_D, \\
(\sigma - pI)n &= 0 \quad \text{on } \Gamma_N.
\end{align}

Here we used the deviatoric part of the tensor \( \tau \) given by \( \text{dev } \tau \), the matrix trace \( \text{tr } \tau \), and the operator \( \kappa : \mathbb{R}^3 \rightarrow \{ \tau \in \mathbb{R}^{3 \times 3} : \tau + \tau^T = 0 \} \) defined by

\[
\kappa(v) = \frac{1}{2} \begin{pmatrix}
0 & -v_3 & v_2 \\
v_3 & 0 & -v_1 \\
-v_2 & v_1 & 0
\end{pmatrix}.
\]

Note the obvious identities

\[
\nabla v = \varepsilon(v) + \kappa(\text{curl } v), \quad 2\kappa(v)w = v \times w,
\]

for vector fields \( v \) and \( w \) (the first of which was already used in (2a)). We will refer to system (1) as the primal formulation and system (2) as the mixed formulation.

The literature on discretizations of (1) and (2) is too vast to list here. The relatively recent quest for exactly divergence-free velocity solutions and pressure-independent a priori error estimates for velocity, often referred to as pressure robust estimates [26, 23], has rejuvenated the field. A recurring theme in this vast literature, from the early non-conforming method of [10] to the more recent [25], is the desire to improve computational efficiency by minimizing inter-element coupling. However, less studied are its side effects on stability when the actual physical flux replaces the often-used simplified diffusive flux, i.e., when

\[
- \text{div}(\nu \varepsilon(u)) \quad \text{replaces} \quad - \text{div}(\nu \nabla u),
\]

even though an early work [11] cautions how the lowest order method of [10] can become unstable when doing so. Such instabilities arise because the larger null space of \( \varepsilon \) necessitates increased inter-element coupling (as explained in more detail below) and are manifested in certain lowest order cases with insufficient inter-element coupling. In this work, focusing on the lowest order case, we identify new stable finite element methods, with the minimal necessary inter-element coupling, that yield exactly divergence-free and pressure robust velocities. New methods based on both the primal and the mixed formulations are designed.

Yet another reason for focusing on the lowest order case is its utility in preconditioning. Roughly speaking, a common strategy for preconditioning high order Stokes discretizations involves combining local (high order) error dampers via, say block Jacobi or other smoothers, with a global (low order) error corrector such as multigrid (or even a direct solver) applied to the smaller lowest order discretization. From this point of view, it is desirable to have stable low order versions (that remain stable under (4))
of high order methods for design of preconditioners, an interesting topic which we shall not touch upon further in this paper.

To delve deeper into the mechanics of the above-mentioned instability, consider the kernel of \( \varepsilon \), consisting of rigid displacements of the form \( x \rightarrow a + b \times x \) with \( a, b \in \mathbb{R}^3 \). Reasonable methods approximating the operator \( -\text{div}(\nu \varepsilon(u)) \) produce element matrices whose nullspaces contain these rigid displacements. Ideally, when these element-wise rigid displacements are subjected to the inter-element continuity conditions of the discrete velocity space, they should equal element-wise restrictions of a global rigid displacement on \( \Omega \) (which can then be eliminated by boundary conditions). However, if the inter-element coupling in the discrete velocity space is so weak to allow for the existence of a \( u \) in it that does not equal a global rigid displacement on \( \Omega \) even though \( u|_T \) is a rigid displacement on every mesh element \( T \), then instabilities can arise.

The discrete velocity space we have in mind is the lowest order (piecewise linear) \( H(\text{div}) \)-conforming Brezzi-Douglas-Marini (BDM) space \([4]\). (A basic premise of this paper is the unquestionable utility of \( H(\text{div}) \)-conforming velocity spaces to obtain exactly divergence-free discrete Stokes velocity fields, well established in prior works \([8, 9, 25, 18, 19]\).) Hence, to understand how to avoid the above-mentioned instability while setting velocity in the BDM space, we ask the following question: how many coupling degrees of freedom (dofs) are needed to guarantee that two rigid displacements \( u_\pm \), given respectively on two adjacent elements \( T_\pm \), coincide on the common interface \( F = \partial T_+ \cap \partial T_- \)?

The pictorial representations of the deformations created by \( u_\pm \) in Figure 1 lead to the answer. Three of the pictured deformations are just translations (generated by the \( a \)-vector in \( a + b \times x \)). For a unit vector \( b \), letting \( R_\theta^b \) denote the unitary operator that performs a counterclockwise rotation by angle \( \theta \) around \( b \), it is easy to see that \( R_\theta^b x = x + \theta(b \times x) + O(\theta^2) \) as \( \theta \to 0 \). Therefore the deformation created by the rigid displacement \( b \times x \) can be viewed as an infinitesimal rotation about \( b \). These

\begin{figure}[h]
\centering
\includegraphics[width=0.7\textwidth]{figure1.png}
\caption{Configurations of adjacent elements after deformation by piecewise rigid displacements of two adjacent elements \( T_\pm \).}
\end{figure}
Figure 2. Classification of facet dofs in our new methods into three types: (1) normal velocity components in the form of $BDM_1$ facet dofs, (2) tangential facet velocities, (3) normal vorticity as $RT^0$ facet dof.

deformations are portrayed in Figure 1 as rotations about three differently directed $b$-vectors. The first row in Figure 1 illustrates deformations generated by piecewise rigid displacements forbidden in the $BDM_1$ space due to their discontinuous normal component on $F$: they are given by two $b$-vectors coplanar with $F$ and an $a$-vector normal to $F$. In other words, the three $BDM_1$ dofs of the facet $F$ illustrated in the left diagram in Figure 2 “control” the rigid displacements portrayed in the first row of Figure 1.

It remains to control the rigid displacements of the second row of Figure 1 using three additional dofs per facet. To this end, our new methods have two additional spaces: (i) one that approximates the in-plane components of the velocity on facets, illustrated in the middle diagram of Figure 2, used to control the first two rigid displacements in the second row of Figure 1; and (ii) a second space, schematically indicated in the last diagram of Figure 2, that controls the third deformation in the second row of Figure 1. The latter deformation arises from piecewise rigid displacements of the form $u_± = b_± \times x$ with $b_\perp$ collinear to $n$, a unit normal of $F$. Since $\text{curl}(b_\perp \times x) = 2b_\perp$, we can make the two rigid displacements coincide on $F$ by requiring continuity of $n \cdot \text{curl} u_\perp$. While continuity of $n \cdot \text{curl} u$ certainly holds if $u$ is the exact Stokes velocity, it does not generally hold for $u$ in $BDM_1$. Hence, keeping in view that $\omega = \text{curl} u$ represents vorticity, we incorporate this constraint in our new methods by approximating vorticity $\omega$ in the lowest order Raviart-Thomas space. This is our second additional space. Its single dof per facet is shown schematically in the last diagram of Figure 2.

In the first part of the paper we will employ these additional spaces to construct a novel HDG method to approximate (1) and present a detailed stability and error analysis. HDG methods have become popular ever since its introduction in [7] which showed how interface variables, or facet variables, can be effectively used to construct DG schemes amenable to static condensation. In the method presented here, the interface variable approximates the tangential components of the velocity. The key technical ingredient in the analysis that reflects the insight garnered from the above pictorial discussion is a discrete Korn-like inequality for the $BDM_1$ space (see Lemma 3.1 below, and the version with interface variables in Lemma 3.2).

The second part of this work discusses the derivation of a novel mixed method for the approximation of (2) and is motivated by our previous two papers [18, 19] and the
many other works on discretizing (2) such as [12, 13, 14, 15]. In [19] we derived the “Mass-Conserving Stress-yielding” (MCS) formulation where the symmetry of $\sigma$ was incorporated in a weak sense by means of a Lagrange multiplier that approximates $\omega = \text{curl} \, u$. While the $\omega$ there was approximated using element-wise linear (or higher degree) functions without any inter-element continuity requirements, the new mixed method we propose here will approximate $\omega$ in the lowest order Raviart-Thomas space instead. The lowest order case that was proved to be stable in [19] had nine coupling dofs per facet. We are able to reduce this number to the minimal six (the dimension of rigid displacements) in this paper. This minimal coupling was achieved earlier in [31] using a bubble-augmented velocity space which is a subspace of a degree-four vector polynomial space. Since higher degrees necessitate more expensive integration rules, we offer our simpler elements as an alternative.

Other methods that approximate the operator $\text{div}(\nu \nabla u)$, such as [10, 25, 18], are able to reduce the number of coupling dofs per facet even further. Since our focus here is on methods that approximate $\text{div}(\nu \varepsilon(u))$, we restrict ourselves to a brief remark on this. Since the kernel of $\nabla$ (applied to vector fields) is three dimensional, we expect the minimal number of coupling dofs per facet to be three when approximating $\text{div}(\nu \nabla u)$. A method with this minimal coupling was achieved early by [10]. To also obtain pressure robust and exactly divergence-free solutions, prior works [25, 18] settled for a slightly higher five coupling dofs per facet in the lowest order case. It is now known that this can be improved by employing the technique of “relaxed $H(\text{div}, \Omega)$-conformity,” see [21, 22], which results in a method with the minimal three coupling dofs per facet and yet, thanks to a simple post-processing, provides optimal convergence orders and pressure robustness.

The new HDG method and the new mixed method proposed in this paper both have the same coupling dofs, same velocity convergence orders and same structure preservation properties like pressure robustness and mass conservation. On closer comparison, two advantages of the mixed method are notable. One is its direct approximation of viscous stresses. Another is the absence of any stabilization parameters in it. In fact, in our numerical studies, the conditioning of a matrix block arising the parameter-free mixed method was found to be better than the analogous HDG block for all ranges of the HDG stabilization parameter we considered.

Outline. We set up general notation in Section 2 and continue with a description of the variational framework used throughout the paper. Finite element spaces, a discrete Korn-like inequality, and resulting norm equivalences are introduced in Section 3. A list of interpolation operators into these spaces and their properties with references to literature can also be found there. In Section 4 we introduce and analyze the HDG method for the primal set of equations (1) and in Section 5 we do the same for the MCS method for the mixed set of equations (2). Finally, in Section 6 we perform numerical experiments to illustrate and complement our theoretical findings.

2. Notation and weak forms

By $\mathbb{M}$ we denote the vector space of real $3 \times 3$ matrices and by $\mathbb{K}$ we denote the vector space of $3 \times 3$ skew symmetric matrices, i.e., $\mathbb{K} = \text{skw}(\mathbb{M})$. Further, let $\mathbb{D} = \text{dev}(\mathbb{M})$. To indicate vector and matrix-valued functions on $\Omega$, we include the
range in the notation, thus while \( L^2(\Omega) = L^2(\Omega, \mathbb{R}) \) denotes the space of square integrable and weakly differentiable \( \mathbb{R} \)-valued functions on \( \Omega \), the corresponding vector and matrix-valued function spaces are defined by \( L^2(\Omega, \mathbb{R}^3) := \{ u : \Omega \to \mathbb{R}^3 \mid u_i \in L^2(\Omega) \} \) and \( L^2(\Omega, \mathbb{M}) := \{ \tau : \Omega \to \mathbb{M} \mid \tau_{ij} \in L^2(\Omega) \} \), respectively. For any \( \tilde{\Omega} \subseteq \Omega \), we denote by \( \langle \cdot, \cdot \rangle_{\tilde{\Omega}} \) the inner product on \( L^2(\tilde{\Omega}) \) (or its vector- or matrix-valued versions). Similarly, we extend this notation and write \( \| \cdot \|_{\tilde{\Omega}} \) for the corresponding \( L^2 \)-norm of a (scalar, vector, or matrix-valued) function on the domain \( \tilde{\Omega} \). In the case \( \tilde{\Omega} = \Omega \) we will omit the subscript in the inner product, i.e. we have \( \langle \cdot, \cdot \rangle_{\tilde{\Omega}} = \langle \cdot, \cdot \rangle \) and we will use the notation \( \| \cdot \|_0 = \| \cdot \| \).

In addition to the differential operators we have already used, \( \nabla, \varepsilon, \text{curl} \), we understand \( \text{div} \Phi \) as either \( \sum_{i=1}^3 \partial_i \Phi_i \) for a vector-valued function \( \Phi \), or the row-wise divergence \( \sum_{j=1}^3 \partial_j \tau_{ij} \) for a matrix-valued function \( \tau \). In addition to the standard Sobolev spaces \( H^m(\Omega) \) for any \( m \in \mathbb{R} \), we shall also use the well-known spaces \( H(\text{div}, \Omega) = \{ v \in L^2(\Omega, \mathbb{R}^3) : \text{div} \, v \in L^2(\Omega) \} \) and \( H(\text{curl}, \Omega) = \{ v \in L^2(\Omega, \mathbb{R}^3) : \text{curl} \, v \in L^2(\Omega, \mathbb{R}^3) \} \). We use \( H_{0,B}(\Omega), H_{0,B}(\text{div}, \Omega) \) and \( H_{0,B}(\text{curl}, \Omega) \), to denote the spaces of functions whose trace, normal trace and tangential trace respectively vanish on \( \Gamma_B \), for \( B \in \{ D, N \} \). The only somewhat nonstandard Sobolev space that we shall use is

\[
H(\text{curl} \, \text{div}, \Omega) := \{ \tau \in L^2(\Omega, \mathbb{R}^3) : \text{div} \, \tau \in H_{0,D}(\text{div}, \Omega)^* \},
\]

where \( H_{0,D}(\text{div}, \Omega)^* \) is the dual space of \( H_{0,D}(\text{div}, \Omega) \). In the case \( \Gamma_D = \partial \Omega \), as proved in [18], the dual of \( H_{0,D}(\text{div}, \Omega) \) equals \( H^{-1}(\text{curl}, \Omega) \), so the condition that \( \text{div} \, \tau \in H_{0,D}(\text{div}, \Omega)^* \) in (5) is the same as requiring that \( \text{curl} \, \text{div} \, \tau \in H^{-1}(\Omega) \). This explains the presence of the operator “curl div” in the name of the space in (5).

We denote by \( \mathcal{T} \) a quasiuniform and shape regular triangulation of the domain \( \Omega \) into tetrahedra. Let \( h \) denote the maximum of the diameters of all elements in \( \mathcal{T} \). Throughout this work we write \( A \sim B \) when there exist two constants \( c, C > 0 \) independent of the mesh size \( h \) as well as the viscosity \( \nu \) such that \( cA \leq B \leq CA \).

Similarly, we use the notation \( A \lesssim B \) if there exists a similar constant \( C \) (independent of \( h \) and \( \nu \)) such that \( A \leq CB \). Henceforth we assume that \( \nu \) is a constant. Due to quasiuniformity we have \( h \sim \text{diam}(T) \) for any \( T \in \mathcal{T} \). The set of element interfaces and boundaries is denoted by \( \mathcal{F} \). This set is further split into facets on the Dirichlet boundary, \( \mathcal{F}_D = \{ F \in \mathcal{F} : F \subset \Gamma_D \} \), facets on the Neumann boundary \( \mathcal{F}_N = \{ F \in \mathcal{F} : F \subset \Gamma_N \} \) and facets in the interior \( \mathcal{F}^0 = \mathcal{F} \setminus (\mathcal{F}_N \cup \mathcal{F}_D) \). Also let \( \mathcal{F}_{0,D} = \mathcal{F}_0 \cup \mathcal{F}_D \).

For piecewise smooth functions \( v \) on the mesh, \( [v] \) and \( \{v\} \) are functions on \( \mathcal{F} \) whose values on each interior facet equal the jump (defined up to a sign) of \( v \) and the mean of the values of \( v \) from adjacent elements. On boundary facets, they are both defined to be the trace of \( v \). On each element boundary, and similarly on each facet on the global boundary we denote by \( n \) the outward unit normal vector. Then the normal and tangential trace of a smooth enough vector field \( v \) is given by

\[
v_n = v \cdot n \quad \text{and} \quad v_t = v - v_n n.
\]

Accordingly, the normal trace is a scalar function and the tangential trace is a vector function. In a similar manner we introduce the normal-normal (\( nn \)) trace and the normal-tangential (\( nt \)) trace of a matrix valued function \( \tau \) by

\[
\tau_{nn} := \tau : n \otimes n = n^T \tau n \quad \text{and} \quad \tau_{nt} = (\tau n)_t.
\]
For any $\tilde{\Omega} \subseteq \Omega$, we denote by $P_k(\tilde{\Omega}) = P_k(\tilde{\Omega}, \mathbb{R})$ the set of polynomials of degree at most $k$, restricted to $\tilde{\Omega}$. Let $P^k(\Omega, \mathbb{R}^3)$ and $P^k(\tilde{\Omega}, \mathbb{M})$ denote the analogous vector- and matrix-valued versions whose components are in $P^k(\Omega)$. With respect to these spaces we then define $\Pi^k_k$, the $L^2(\Omega)$-projection into the space $P^k(\tilde{\Omega})$ or its vector- or matrix-valued versions. We omit subscript from $\Pi^k_k$ if it is clear from context. For the space of functions the restrictions of which are in $P^k(T)$ for all $T \in T$ we write simply $P^k(T)$. The analogous convention holds for $H^k(T)$, $L^2(F)$, etc.

The standard [16] variational formulation of (1) is to find $(u, p) \in H^1_{0,D}(\Omega, \mathbb{R}^3) \times L^2(\Omega)$ such that

\begin{align}
\nu(\varepsilon(u), \varepsilon(v)) - (\text{div } v, p) &= (f, v) \quad \text{for all } v \in H^1_{0,D}(\Omega, \mathbb{R}^3), \tag{6a} \\
-(\text{div } u, q) &= 0 \quad \text{for all } q \in L^2(\Omega). \tag{6b}
\end{align}

However our novel methods use $H(\text{div})$-conforming spaces for the approximation of the velocity $u$. Another weak form where velocity is set in $H(\text{div})$ was given in [18, 19, 24] using $\Sigma^\text{sym} := \{ \tau \in H(\text{curl } \text{div } \Omega) : \tau = \tau^T \}$. It finds $(\sigma, u, p) \in \Sigma^\text{sym} \times H^1_{0,D}(\text{div }, \Omega) \times L^2(\Omega)$ such that

\begin{align}
(\nu^{-1} \sigma, \tau) + \langle \text{div } \tau, u \rangle_{\text{div}} &= 0 \quad \text{for all } \tau \in \Sigma^\text{sym}, \tag{7a} \\
-\langle \text{div } \sigma, v \rangle_{\text{div}} - (\text{div } v, p) &= (f, v) \quad \text{for all } v \in H^1_{0,D}(\text{div }, \Omega), \tag{7b} \\
-(\text{div } u, q) &= 0 \quad \text{for all } q \in L^2(\Omega), \tag{7c}
\end{align}

where $\Sigma^\text{sym} := \{ \tau \in H(\text{curl } \text{div } \Omega) : \tau = \tau^T \}$. Here $\langle \cdot, \cdot \rangle_{\text{div}}$ denotes the duality pairing on $H^1_{0,D}(\text{div }, \Omega)^* \times H^1_{0,D}(\text{div }, \Omega)$. Note that since $\sigma \in L^2(\Omega, \mathbb{D})$ we have $\text{tr}(\sigma) = 0$ which is motivated by (2a). In [24], a detailed well-posedness analysis of (7) was provided, but in this paper, (7) will serve merely to motivate the new mixed method of Section 5.

3. The finite elements used and their properties

The finite element spaces we use in this paper are as follows:

\begin{align}
V_h := \{ v_h \in H^1_{0,D}(\text{div }, \Omega) : v_h|_T \in P^1(T, \mathbb{R}^3) \}, \tag{8a} \\
\hat{V}_h := \{ \hat{v}_h \in L^2(F, \mathbb{R}^3) : \hat{v}_h = 0 \text{ on } \Gamma_D, \text{ and for all } F \in F, \hat{v}_h|_F \in P^0(F, \mathbb{R}^3) \text{ and } (\hat{v}_h)_n|_F = 0 \}, \tag{8b} \\
W_h := \{ \eta_h \in H^1_{0,D}(\text{div }, \Omega) : \eta_h|_T \in P^0(T, \mathbb{R}^3) + xP^0(T, \mathbb{R}) \text{ for all } T \in T \}, \tag{8c} \\
\Sigma_h := \{ \tau_h \in L^2(\Omega, \mathbb{D}) \text{ : } \tau_h|_T \in P^1(T, \mathbb{D}), (\tau_h)_n|_F \in P^0(F, \mathbb{R}^2) \}, \tag{8d} \\
Q_h := P^0(T). \tag{8e}
\end{align}

Let $n_F$ denote a unit normal of any facet $F \in F$. Note that for any $\tau_h \in \Sigma_h$, on a facet $F$, $(\tau_h)_n : F \to n_F^\perp$, where $n_F^\perp$ denotes the orthogonal complement of $n_F$, but in (8d), we have slightly abused notation, and written $(\tau_h)_n \in P^0(F, \mathbb{R}^2)$, identifying $n_F^\perp$ with $\mathbb{R}^2$. Also any $\hat{v}_h \in \hat{V}_h$ is tangential and takes values in $n_F^\perp$ on each facet $F$. Note also that $V_h$, which equals $H^1_{0,D}(\text{div }, \Omega) \cap BDM^1$ in the notation of §1, is the lowest order Brezzi-Douglas-Marini space while $W_h$ is the lowest order Raviart-Thomas space [4]. The space $\Sigma_h$ is a discontinuous version of the “nt-continuous” space introduced in [18], for which simple shape functions were exhibited there. All of these finite element spaces are obtained by mappings from a single reference finite element. (All these maps extend
to curvilinear elements, although we restrict to affine equivalent elements in our analysis here.) The maps are compatible with the degrees of freedom of the spaces. (For $\Sigma_h$, the appropriate map is given in [18] and compatibility with degrees of freedom is proved in [18, Lemma 5.7], while for the other spaces, the mappings are standard.) In the case of $V_h$ and $W_h$, the maps are Piola maps which also preserve divergence-free subspaces.

3.1. A discrete Korn-type inequality. Korn inequalities for piecewise functions were given in [5, Theorem 3.1]. A further refinement was given in [27, Theorem 3.1]. To describe it, let $\Pi$ were given in [5, Theorem 3.1]. A further refinement was given in [27, Theorem 3.1].

To describe it, let $\Pi$ orthogonal projection onto the one dimensional span of $r$. By Pythagoras theorem, for all $v 
abla |p F T Ò˚} 2 \Pi^R [u] t F0_D \sim \|\varepsilon(u)\|^2_T + h^{-1}\|\Pi^0 [u] t F0_D \|

Proof. By Pythagoras theorem,

$$\|\Pi^R [u] t F \|^2_F = \|\Pi^0 [u] t F \|^2_F + \|(\Pi^R - \Pi^0) [u] t F \|^2_F.$$ 

Hence (10) would follow once we prove that for all $F \in \mathcal{F}$ and all $u_h \in V_h$,

$$h\|\text{curl } u_h\|_F^2 + \sum_{T \in T_F} \|\varepsilon(u)\|^2_T \sim h^{-1}\|(\Pi^R - \Pi^0) [u] t F \|^2_F + \sum_{T \in T_F} \|\varepsilon(u)\|^2_T,$$

where $T_F = \{T \in \mathcal{T} : F \subset \partial T\}$.

To prove (11), first note that, restricted to every facet $F$, $\Pi^R - \Pi^0$ is the $L^2(F)$-orthogonal projection onto the one dimensional span of $r_F = n_F \times (x - x_F)$ where $x_F = \frac{1}{|F|} \int_F x \, dx$ is the barycenter of $F$. Computing this one-dimensional projection,

$$\|(\Pi^R - \Pi^0) [u] t F \|_F = (r_F, [u] t F r_F) / |r_F|^2_F.$$ 

Therefore,

$$\|(\Pi^R - \Pi^0) [u] t F \|_F = \frac{|(r_F, [u] t F)|}{|r_F|^2_F}.$$ 

To simplify the numerator of the last term, let $w$ equal $u_h|_T$ for some $T \in T_F$. We claim that

$$(r_F, w)_F = (r_F, \varepsilon(w)(x - x_F))_F + \frac{1}{2}(|x - x_F|^2, n_F \cdot \text{curl } w)_F.$$
To see why, recalling that \( w \) is linear in \( T \) (and hence in \( F \subset \partial T \)), for any \( x \in F \),
\[
  w(x) = w(x_F) + \nabla w (x - x_F)
  = w(x_F) + \varepsilon(w)(x - x_F) + \frac{1}{2} \text{curl} \, w \times (x - x_F),
\]
where we have used (3). Since \( r_F \) is orthogonal to constants on \( F \),
\[
  (r_F, w) = (r_F, \varepsilon(w)(x - x_F))_F + \frac{1}{2} (n_F \times (x - x_F), \text{curl} \, w \times (x - x_F))_F.
\]
Now, since \( (x - x_F) \perp n \) for any \( x \in F \), using the identity \((a \times b) \cdot (c \times b) = |b|^2 (a \cdot c) - (a \cdot b)(c \cdot b)\) to simplify the last term, we obtain (13).

The equivalence of (11) is a consequence of the identity
\[
  \| (\Pi^R - \Pi^0) [u_h]_F \|_F = \frac{(r_F, [\varepsilon(u_h)]_F (x - x_F))_F}{\| r_F \|_F} + \frac{(\| x - x_F \|^2, [\text{curl} \, u_h]_n)_F}{2 \| r_F \|_F},
\]
(14) immediately obtained by combining (12) and (13). Indeed, by applying Cauchy-Schwarz inequality to the terms on the right hand side of (14), simple local scaling arguments give \( h^{-1} \| (\Pi^R - \Pi^0) [u_h]_F \|_F^2 \lesssim \sum_{T \in \mathcal{T}_h} \| \varepsilon(u_h) \|_T^2 + h \| [\text{curl} \, u_h]_n \|_F^2 \), thus proving one side of equivalence in (11). To prove the other side, we begin by noting that \( \text{curl} \, (u_h) \) is constant on each element, so
\[
  h^{1/2} \| [\text{curl} \, u_h]_n \|_F \lesssim h^{-1/2} \| (\Pi^R - \Pi^0) [u_h]_F \|_F \frac{(\| x - x_F \|^2, [\text{curl} \, u_h]_n)_F}{2 \| r_F \|_F}
  = h^{-1/2} \left( \| (\Pi^R - \Pi^0) [u_h]_F \|_F - \frac{(r_F, [\varepsilon(u_h)]_F (x - x_F))_F}{\| r_F \|_F} \right)
  \lesssim h^{-1/2} \| (\Pi^R - \Pi^0) [u_h]_F \|_F + \sum_{T \in \mathcal{T}_h} \| \varepsilon(u_h) \|_T,
\]
where we have used (14) and local scaling arguments again. Squaring both sides and applying Young’s inequality, (11) is proved.

3.2. Norm equivalences. The product space for the kinematic variables is given by \( U_h := V_h \times \hat{V}_h \times W_h \). For the analysis we define the norms
\[
  \| u_h, \hat{u}_h \|_{V_h}^2 := \| \nabla u_h \|_T^2 + h^{-1} \| \Pi^0(u_h - \hat{u}_h) \|_{\partial T}^2,
  \| u_h, \hat{u}_h, \omega_h \|_{V_h}^2 := \| \varepsilon(u_h) \|_T^2 + h^{-1} \| \Pi^0(u_h - \hat{u}_h) \|_{\partial T}^2 + h \| (\text{curl} \, u_h - \omega_h)_n \|_{\partial T}^2,
  \| u_h, \hat{u}_h, \omega_h \|_{\hat{V}_h}^2 := \| \varepsilon(u_h) \|_T^2 + h^{-1} \| \Pi^0(u_h - \hat{u}_h) \|_{\partial T}^2 + \| \text{curl} \, u_h - \omega_h \|_{\partial T}^2,
  \| u_h, \hat{u}_h, \omega_h \|_{U_h}^2 := \| \text{dev} \, \nabla u_h - \Pi^0\kappa(\omega_h) \|_T^2 + h^{-1} \| \Pi^0(u_h - \hat{u}_h)_t \|_{\partial T}^2,
\]
where we have used \( \| \cdot \|_{\partial T}^2 \) to abbreviate \( \sum_{T \in \mathcal{T}} \| \cdot \|_{\partial T}^2 \). We will shortly establish relationships between these norms (Lemma 3.4). That these are all norms on \( U_h \) may not be immediately obvious, but follows from Lemma 3.2 below (where we critically use that \( \hat{u}_h \) is single valued on facets). As we shall see later, \( \| \cdot \|_\varepsilon \) is the natural norm to analyze the new HDG method in §4, while \( \| \cdot \|_\varepsilon \) features in the analysis of the MCS method in §5. All the above norms involve the interface variable \( \hat{u}_h \), so they may be referred.
to as “HDG-type” norms. In contrast, “DG-type” norms were used in Subsection 3.1, where Lemma 3.1 and (9) imply
\[
\|\nabla u_h\|_T \leq \|\varepsilon(\Delta u_h)\|^2_T + h^{-1}\|\Pi^0 u_h\|_{\mathcal{F}_0}^2 + h\|\text{curl } u_h\|_{\mathcal{F}_{0,D}}^2. \tag{15}
\]
A similar discrete Korn-type inequality also holds for HDG-type norms, as seen in the next lemma.

**Lemma 3.2.** For all \((u_h, \hat{u}_h, \omega_h) \in U_h\), we have the Korn-like inequality
\[
\|u_h, \hat{u}_h\|_\nabla \leq \|u_h, \hat{u}_h, \omega_h\|_\varepsilon. \tag{16}
\]
The reverse inequality holds in the sense that for any \((u_h, \hat{u}_h) \in V_h \times \hat{V}_h\) there exists a \(\omega_h \in W_h\) such that
\[
\|u_h, \hat{u}_h, \omega_h\|_\varepsilon \leq \|u_h, \hat{u}_h\|_\nabla. \tag{17}
\]

**Proof.** To prove (16), first note that on an interior facet \(F = \partial T \cap \partial T_\perp \in \mathcal{F}_0\) shared by two elements \(T_\pm \in \mathcal{T}\), let \(u_h^\pm = u_h|_{T_\pm}\), since \(\hat{u}_h\) is single valued on \(F\), we have \(u_h^+ - u_h^- = (u_h^+ - \hat{u}_h) - (u_h^- - \hat{u}_h)\). Moreover, on a facet \(F \in \mathcal{F}_D\), \(u_h|_F = (u_h - \hat{u}_h)|_F\). Thus by triangle inequality,
\[
\|\Pi^0 u_h\|_{\mathcal{F}_0}^2 \leq 2\|\Pi^0 (u_h - \hat{u}_h)\|_{\mathcal{F}_D}^2, \tag{18}
\]
where we have increased the right hand side to include facets on \(\Gamma^N\) also. Similarly, since the normal component of the given \(\omega_h \in W_h\) is continuous across \(F \in \mathcal{F}_0\) and zero on \(F \in \mathcal{F}_D\),
\[
\|\text{curl } u_h\|_{\mathcal{F}_{0,D}}^2 \leq 2\|\text{curl } u_h - \omega_h\|_{\mathcal{F}_{0,D}}^2. \tag{19}
\]
Using (18) and (19) in (15), we obtain the estimate (16).

To prove (17), consider a function \(\omega_h \in W_h\) satisfying
\[
n \cdot \omega_h = n \cdot \{\text{curl } u_h\} \quad \text{on } \partial T \cap \Gamma^D,
\]
\[
n \cdot \omega_h = 0 \quad \text{on } \partial T \cap \Gamma^D,
\]
on the boundary of every element \(T \in \mathcal{T}\). Since \(\text{curl } u_h\) is piecewise constant, by the well known degrees of freedom of the Raviart-Thomas space \(W_h\), these conditions uniquely fix an \(\omega_h \in W_h\). Then, \(\|\text{curl } u_h - \omega_h\|_{F}\) equals zero for \(F \in \mathcal{F}_N\), equals \(\frac{1}{2}\|\text{curl } u_h\|_{\mathcal{F}_{0,D}}\) for \(F \in \mathcal{F}_0\), and equals \(\|\text{curl } u_h\|_{F}\) for \(F \in \mathcal{F}_D\), so
\[
\|\text{curl } u_h - \omega_h\|_{\mathcal{F}_{0,D}}^2 \leq \|\text{curl } u_h\|_{\mathcal{F}_{0,D}}^2. \tag{19}
\]
Therefore, for this choice of \(\omega_h\), we have
\[
\|u_h, \hat{u}_h, \omega_h\|_\varepsilon \leq \|\varepsilon(u_h)\|_{\mathcal{F}_{0,D}}^2 + h\|\text{curl } u_h\|_{\mathcal{F}_{0,D}}^2 + h^{-1}\|\Pi^0 (u_h - \hat{u}_h)\|_{\mathcal{F}_{0,D}}^2. \tag{17}
\]
By a local scaling argument \(h\|\text{curl } u_h\|_{\mathcal{F}_{0,D}}^2 \leq \|\text{curl } u_h\|_{\mathcal{F}_{0,D}}^2\). Using this in the above inequality and recalling that \(\|\nabla u_h\|_{\mathcal{F}_{0,D}}^2 = \|\varepsilon(u_h)\|_{\mathcal{F}_{0,D}}^2 + \|\kappa(\text{curl } u_h)\|_{\mathcal{F}_{0,D}}^2\), we complete the proof of (17). \(\square\)
Lemma 3.3. For any $u_h \in V_h$, $\omega_h \in W_h$, and $T \in \mathcal{T}$,
\[
\| \text{curl } u_h - \omega_h \|_T^2 \sim h \| (\text{curl } u_h - \omega_h)_n \|_T^2, \tag{20a}
\]
\[
\| \text{curl } \kappa(\omega_h) \|_T \sim \| \kappa(\omega_h) \|_{H^1(T)}^2 \sim \| \text{div } \omega_h \|_T, \tag{20b}
\]
\[
\| \varepsilon(u_h) \|_T^2 + \| \text{curl } u_h - \omega_h \|_T^2 \sim \| \text{dev } \nabla u_h - \Pi^0 \kappa(\omega_h) \|_T^2 + h^2 \| \text{div } \omega_h \|_T^2 + \| \text{div } u_h \|_T^2. \tag{20c}
\]

Proof. The first equivalence follows by standard scaling arguments (by equivalence of norms in the lowest order Raviart-Thomas space). Equivalence (20b) also follows by local scaling arguments and [19, eq. (4.14)]. We continue on to prove (20c). Applying the Pythagorean theorem twice,
\[
\| \varepsilon(u_h) \|_T^2 + \frac{1}{2} \| \text{curl } u_h - \omega_h \|_T^2 = \| \nabla u_h - \kappa(\omega_h) \|_T^2
\]
\[
= \| \text{dev } \nabla u_h - \kappa(\omega_h) \|_T^2 + \frac{1}{3} \| \text{div } u_h \|_T^2. \tag{21}
\]

We also have, due to (20b),
\[
h^2 \| \text{div } \omega_h \|_T^2 \sim h^2 \| \text{curl } (\kappa(\omega_h)) \|_T^2 = h^2 \| \text{curl } (\kappa(\omega_h - \text{curl } u_h)) \|_T^2
\]
\[
\leq \| \omega_h - \text{curl } u_h \|_T^2. \tag{22}
\]

Here we have used an inverse inequality and the observation that derivatives of $\text{curl } u_h \in P^0(T)$ vanish. Combining (21), (22) and the continuity of the $L^2$ projection, we conclude that the right side of (20c) can be bounded by the left side.

For the reverse inequality,
\[
\| \text{dev } \nabla u_h - \kappa(\omega_h) \|_T^2 = \| \Pi^0(\text{dev } \nabla u_h - \kappa(\omega_h)) \|_T^2 + \| (\mathbb{I} - \Pi^0)\kappa(\omega_h) \|_T^2
\]
\[
\leq \| \text{dev } \nabla u_h - \Pi^0 \kappa(\omega_h) \|_T^2 + h^2 \| \kappa(\omega_h) \|_{H^1(T)}^2 + \| \text{div } \omega_h \|_T^2. \tag{23}
\]

Here, we used that $\text{dev } \nabla u_h \in P^0(T)$, a standard approximation estimate for the $L^2$ projection, followed by (20b). The proof is then concluded using (21). \qed

Lemma 3.4. For all $(u_h, \tilde{u}_h, \omega_h) \in U_h$,
\[
\| u_h, \tilde{u}_h, \omega_h \|_\varepsilon \sim \| u_h, \tilde{u}_h, \omega_h \|_\varepsilon \sim \| u_h, \tilde{u}_h, \omega_h \|_{L^2} + \| \text{div } u_h \|_0^2 + h^2 \| \text{div } \omega_h \|_0^2.
\]

Proof. This is a direct consequence of Lemma 3.3. \qed

3.3. Interpolation operators. In subsequent sections we will require the interpolation operators into the spaces in (8a)-(8e), denoted by

\[
I_V : H^1_{n,D}(\mathcal{T}) \to V_h, \quad I_W : H^1_{n,D}(\mathcal{T}) \to W_h, \quad I_\nabla : L^2(\mathcal{F}, \mathbb{R}^3) \to \nabla V_h, \quad I_\Sigma : \Sigma \to \Sigma_h,
\]

where $\Sigma = \{ \tau \in H^1(\mathcal{T}, \mathbb{D}) : [\tau]_{nt} = 0 \}$. Of course, the natural interpolation for $Q_h$, denoted by $I_Q : L^2(\Omega) \to Q_h$, is simply the $L^2$-orthogonal projection. The definitions and properties of the remaining interpolants are summarized in this subsection.

An $H(\text{div})$-interpolation into $V_h$, denoted by $I_V : H^1_{n,D}(\mathcal{T}) \to V_h$, is defined using the standard degrees of freedom (see e.g., [4, Proposition 2.3.2]):
\[
\int_F (u - I_V u)_n q \, ds = 0 \quad \text{for all } q \in P^1(F) \text{ and } F \in \mathcal{F}. \tag{24}
\]
A well-known consequence of (24) is that
\[ \text{div}(I_V u) = I_Q \text{div} u, \] \hspace{1cm} (25)
for all \( u \) in the domain of \( I_V \). The interpolant \( I_W : H^1_{n,D}(T) \to W_h \), defined by \( ((\omega - I_W \omega)_n, q)_F = 0 \) for all \( q \in P^0(F) \) and all \( F \in \mathcal{F} \), is also standard. The interpolation operator for the stress space \( I_\Sigma : \Sigma \to \Sigma_h \), borrowed from [18], is defined by

\[ \int_F (I_\Sigma \sigma - \sigma)_{nt} : q \, ds = 0, \quad \text{for all } q \in P^0(F, \mathbb{R}^3) \text{ with } q_n = 0, \quad \text{for all } F \in \mathcal{F}, \] \hspace{1cm} (26)
\[ \int_T (I_\Sigma \sigma - \sigma) : q \, dx = 0, \quad \text{for all } q \in P^0(T, \mathbb{R}), \quad \text{for all } T \in \mathcal{T}. \] \hspace{1cm} (27)

Finally, the tangential \( L^2 \)-projection on facets, \( I_{\Sigma} : L^2(\mathcal{F}, \mathbb{R}^3) \to \hat{V}_h \) is defined as usual by \( ((\hat{u} - I_{\Sigma} \hat{u})_t, q)_F = 0 \) for all \( q \in P^0(F, \mathbb{R}^3) \) with \( q_n = 0 \) on all \( F \in \mathcal{F} \).

To note the salient approximation properties of these interpolants, first observe that for a \( u \in H^1(\Omega, \mathbb{R}^3) \cap H^2(\mathcal{T}) \), we have \( \text{curl}(u) \in H^1_{n,D}(\mathcal{T}) \). Hence \( (I_V u, I_{\Sigma} u, I_W \text{curl}(u)) \) is in \( U_h \) and using standard scaling arguments and the Bramble-Hilbert lemma, we get

\[ \| u - I_V u, u_t - I_{\Sigma} u_t, \text{curl} u - I_W \text{curl} u \|_2^2 + \| u - I_V u, u_t - I_{\Sigma} u_t \|_{2, T}^2 + h \| \varepsilon(I_V u - u)_{nt} \|_{\partial T}^2 \lesssim h^2 \| u \|_{H^2(\mathcal{T})}. \] \hspace{1cm} (28)

Also recall that [18, Theorem 5.8] implies that for all \( \sigma \in \Sigma \),

\[ \| \sigma - I_\Sigma \sigma \|_2^2 + h \| (\sigma - I_\Sigma \sigma)_{nt} \|_{\partial T}^2 \lesssim h^2 \| \sigma \|_{H^2(\mathcal{T})}. \] \hspace{1cm} (29)

4. An \( H(\text{div}) \)-conforming velocity–vorticity HDG scheme

4.1. Derivation of the HDG method. To derive our new HDG scheme for (6), let \( u, p \) be a sufficiently smooth exact solution of (1). (A sufficient smoothness condition is quantified in Lemma 4.1 below.) Let \( v_h \in V_h \). Then, multiplying (1a) by \( v_h \) and integrating by parts on each element,

\[ (f, v_h) = (\varepsilon(\varepsilon(u)) + \nabla p, v_h) = -(p, \text{div} v_h) + \sum_{T \in \mathcal{T}} \int_T \varepsilon(\varepsilon(u)) : \varepsilon(v_h) \, dx \] \hspace{1cm} (30a)
\[ + \sum_{T \in \mathcal{T}} \int_{\partial T \setminus \partial \Gamma_N} (p - \varepsilon(\varepsilon(u)) n \cdot v_h) \, ds, \]
where we used the symmetry of \( \varepsilon(u) \) and the boundary condition (1d). Since \( p \) is smooth, \( [v_h]_n = 0 \) on \( \partial F_{0,D} \),

\[ 0 = -\sum_{T \in \mathcal{T}} \int_{\partial T \setminus \partial \Gamma_N} p n \cdot v_h \, ds. \] \hspace{1cm} (30b)

Let \( \hat{v}_h \in \hat{V}_h \). Since \( \hat{v}_h \) is single-valued on all facets, \( \hat{v}_h = 0 \) on \( \Gamma_D \) (see (8b)), and \( \varepsilon(u) \) is continuous across interior facets,

\[ 0 = \sum_{T \in \mathcal{T}} \int_{\partial T \setminus \partial \Gamma_N} \varepsilon(\varepsilon(u)) n \cdot \hat{v}_h \, ds. \] \hspace{1cm} (30c)

Adding (30a)–(30c),

\[ (f, v_h) = -(p, \text{div} v_h) + \sum_{T \in \mathcal{T}} \int_T \varepsilon(\varepsilon(u)) : \epsilon(v_h) \, dx + \sum_{\partial T \setminus \partial \Gamma_N} \varepsilon(\varepsilon(u)) n \cdot (\hat{v}_h - v_h) \, ds, \]
where $(\hat{v}_h)_t = \hat{v}_h$, $[v_h]_h = 0$ on $\mathcal{F}_{0,D}$ and $\varepsilon(u)$ is smooth, we may replace $(\hat{v}_h - v_h)$ by its tangential component $(\hat{v}_h - v_h)_t$ in the last term above. Furthermore, on $\Gamma_N$, we have $\varepsilon(u)n \cdot (\hat{v}_h - v_h)_t = \varepsilon(u)nt \cdot (\hat{v}_h - v_h)_t = 0$ since the tangential part of (1d) shows that $\varepsilon(u)nt = 0$ on $\Gamma_N$. Hence we may also replace $\partial T \setminus \Gamma_N$ by $\partial T$ in the last term. Thus,

$$(f, v_h) = -(p, \text{div } v_h) + \sum_{T \in \mathcal{T}} \int_T \nu \varepsilon(u) : \varepsilon(v_h) \, dx + \int_{\partial T} \nu \varepsilon(u)n \cdot (\hat{v}_h - v_h)_t \, ds. \quad (31a)$$

Next, let $\omega = \text{curl}(u)$ and $\hat{u} = u_t$ on each element boundary $\partial T$. Then, obviously,

$$0 = \sum_{T \in \mathcal{T}} \int_T \nu \varepsilon(v_h)n \cdot (\hat{u} - u)_t \, ds + \sum_{T \in \mathcal{T}} \frac{\nu \alpha}{h} \int_{\partial T} \Pi^0(\hat{u} - u)_t \cdot \Pi^0(\hat{v}_h - v_h)_t \, ds, \quad (31b)$$

$$0 = \sum_{T \in \mathcal{T}} h \int_{\partial T} \nu (\text{curl } u - \omega)_n (\text{curl } v_h - \eta_h)_n \, dx, \quad (31c)$$

for any test function $\eta_h \in W_h$ and constant $\alpha > 0$, i.e., if $u, \hat{u}$ and $\omega$ are replaced by $u_h, \hat{u}_h$ and $\omega_h$, respectively, then the terms on the right are consistent terms.

Adding the equations (31a)–(31c), we obtain

$$\nu a^{\text{hdg}}(u, \hat{u}, \omega; v_h, \hat{v}_h, \eta_h) - (\text{div } v_h, p) = (f, v_h), \quad (32a)$$

where

$$a^{\text{hdg}}(z, \hat{z}, \theta; v_h, \hat{v}_h, \eta_h) := (\varepsilon(z), \varepsilon(v_h))_T$$
$$+ (\varepsilon(z)n, (\hat{v}_h - v_h)_t)_T + ((\hat{z} - z)_t, \varepsilon(v_h)n)_T$$
$$+ \frac{\alpha}{h} (\Pi^0(\hat{z} - z)_t, \Pi^0(\hat{v}_h - v_h)_t)_T + h ((\text{curl } z - \theta)_n, (\text{curl } v_h - \eta_h)_n)_T.$$
Additionally employing (35) and (36). The estimate (39) is a consequence of Cauchy-Schwarz inequality, while (38) follows by additionally employing (35) and (36). Let \( \varepsilon(v_h) \) be constant on \( T \). For the same reason, \( \Pi^0 \) may be introduced into the second and third terms in the definition of \( a^\text{hdg}(u_h, \hat{u}_h, \omega_h; v_h, \hat{v}_h, \eta_h) \), e.g.,

\[
(\varepsilon(u_h)n, (\hat{v}_h - v_h)_t)_{\partial T} = (\varepsilon(u_h)n, \Pi^0(\hat{v}_h - v_h))_{\partial T}.
\]

Let \( \|u, \hat{u}, \omega\|_{\varepsilon, +}^2 = \|u, \hat{u}, \omega\|_{\varepsilon}^2 + h\|\varepsilon(u_h)n\|_{\partial T}^2 + h^{-1}\|\Pi^0(u - \hat{u})\|_{\partial T}^2 \).

**Lemma 4.2** (Continuity of \( a^\text{hdg} \)). For any \((u, \hat{u}, \omega), (u_h, \hat{u}_h, \omega_h) \in U_h \times U_h \times Q_h \),

\[
\nu a^\text{hdg}(u, \hat{u}, \omega; v_h, \hat{v}_h, \eta_h) \leq \nu \|u, \hat{u}, \omega\|_{\varepsilon, +} \|v_h, \hat{v}_h, \eta_h\|_{\varepsilon, +},
\]

\[
\nu a^\text{hdg}(u_h, \hat{u}_h, \omega_h; v_h, \hat{v}_h, \eta_h) \leq \nu \|u_h, \hat{u}_h, \omega_h\|_{\varepsilon} \|v_h, \hat{v}_h, \eta_h\|_{\varepsilon},
\]

\[
(\text{div } u_h, q_h) \leq \|u_h, \hat{u}_h, \omega_h\|_{\varepsilon} \|q_h\|_0.
\]

**Proof.** Inequality (37) follows from Cauchy-Schwarz inequality, while (38) follows by additionally employing (35) and (36). The estimate (39) is a consequence of \( \|\text{div } u_h\|_{\partial T}^2 = \|\varepsilon(u_h)n\|_{\partial T}^2 - \|\text{div } \varepsilon(u_h)n\|_{\partial T}^2 \).

**Lemma 4.3** (Coercivity of \( a^\text{hdg} \)). There is a mesh-independent \( \alpha_0 > 0 \) such that for all \( \alpha > \alpha_0 \) and all \((u_h, \hat{u}_h, \omega_h) \in U_h \),

\[
\nu a^\text{hdg}(u_h, \hat{u}_h, \omega_h; u_h, \hat{u}_h, \omega_h) \geq \nu \|u_h, \hat{u}_h, \omega_h\|_{\varepsilon}^2.
\]

**Proof.** By (36) and Young’s inequality with any \( \beta > 0 \),

\[
a^\text{hdg}(u_h, \hat{u}_h, \omega_h; u_h, \hat{u}_h, \omega_h) \geq \|\varepsilon(u_h)n\|_{\partial T}^2 - \left(\beta h\|\varepsilon(u_h)n\|_{\partial T}^2 + \frac{1}{\beta h}\|\Pi^0(u_h - \hat{u}_h)\|_{\partial T}^2\right)
\]

\[
+ \alpha h^{-1}\|\Pi^0(u_h - \hat{u}_h)\|_{\partial T}^2 + h\|(\text{curl } u_h - \omega_h)n\|_{\partial T}^2.
\]

Hence using (35), and choosing, say \( \beta = 1/(2c_1) \) and \( \alpha = 2/\beta \), (40) follows.

**Lemma 4.4** (LBB condition for the HDG method). For any \( p_h \in Q_h \) there exists a \((v_h, \hat{v}_h, \eta_h) \in U_h \) with \( \|v_h, \hat{v}_h, \eta_h\|_{\varepsilon} \leq \|p_h\|_0 \) and \( \text{div } v_h = p_h \). Consequently,

\[
\sup_{(v_h, \hat{v}_h, \eta_h) \in U_h} \frac{\text{div } v_h, p_h}{\|v_h, \hat{v}_h, \eta_h\|_{\varepsilon}} \geq \|p_h\|_0.
\]
Proof. By classical results [16], there exists a \( u \in H^1(\Omega) \) such that
\[
\text{div } v = p \text{, } \quad \|v\|_{H^1(\Omega)} \lesssim \|p\|_0.
\] (42)

Put \( v_h = I_V v \) and \( \hat{v}_h = I_{\tilde{V}} v \) on each facet. Then, (42) and (25) imply \( \text{div} v_h = \text{div}(I_V v) = I_Q \text{div } v = p_h \). Moreover, (as alluded to in [25]) it is easy to show that
\[
\|v_h, \hat{v}_h\|_{\nabla} \lesssim \|v\|_{H^1(\Omega)}.
\] (43)

Choose \( \eta_h \in W_h \) as in (17) of Lemma 3.2. Then, by (42)–(43),
\[
\|v_h, \hat{v}_h, \eta_h\|_\varepsilon \lesssim \|v_h, \hat{v}_h\|_{\nabla} \lesssim \|v\|_{H^1(\Omega)} \lesssim \|p_h\|_0,
\]
concluding the proof.

\(\square\)

**Theorem 4.5** (Error estimates for the HDG method). Let \( u, \hat{u}, \omega, p \) denote the exact solution that satisfies the regularity assumption of Lemma 4.1 and let \((u_h, \hat{u}_h, \omega_h, p_h) \in U_h \times Q_h \) be the discrete solution of (33). Then the errors in \( u_h, \hat{u}_h, \omega_h \) can be bounded independently of the pressure error by
\[
\|u - u_h, u - \hat{u}_h, \omega - \omega_h\|_\varepsilon \lesssim h \|u\|_{H^2(\Omega)}.
\] (44)

Furthermore, the pressure error satisfies
\[
\nu^{-1} \|p - p_h\|_0 \lesssim h (\|u\|_{H^2(\Omega)} + \nu^{-1} \|p\|_{H^1(\Omega)}).
\] (45)

**Proof.** Let \( E = (u - u_h, \hat{u} - \hat{u}_h, \omega - \omega_h) \) and \( E_h = (I_V u - u_h, I_{\tilde{V}} \hat{u} - \hat{u}_h, I_W \omega - \omega_h) \). Then \( E = E - E_h \) represents the interpolation errors. Since \( E_h \in U_h \),
\[
\nu \|E_h\|_\varepsilon^2 \lesssim \nu a_{\text{hdg}}(E_h; E_h) = \nu a_{\text{hdg}}(E - E_h; E_h)
\]
by Lemma 4.3
\[
= (\text{div}(I_V u - u_h), p - p_h) - \nu a_{\text{hdg}}(E; E_h)
\]
by Lemma 4.1.

By (25), \( \text{div}(I_V u) = I_Q \text{div } u = 0 \). Moreover, by (33b), \( \text{div } u_h = 0 \). Hence
\[
\nu \|E_h\|_\varepsilon^2 = -\nu a_{\text{hdg}}(E; E_h) \lesssim \nu \|E\|_{\varepsilon, +} \|E_h\|_{\varepsilon, +},
\] (46)
by Lemma 4.2. Now we claim that
\[
\|E_h\|_{\varepsilon, +} \lesssim \|E_h\|_\varepsilon.
\] (47)
To see this, first note that local scaling arguments give
\[
h^{-1} \|(I - \Pi^0)v_h\|_{\nabla}^2 \lesssim \|\nabla v_h\|_{\tau}^2,
\] (48)
for any \( v_h \in V_h \). Then, letting \( E_h^u = I_V u - u_h, E_h^{\hat{u}} = I_{\tilde{V}} \hat{u} - \hat{u}_h \), note that on each facet, \((I - \Pi^0)(E_h^u - E_h^{\hat{u}}) = (I - \Pi^0)E_h^u\). Hence the extra terms in \( \|E_h\|_{\varepsilon, +} \) that are not in \( \|E_h\|_\varepsilon \) can be bounded by applying (48) and (35) with \( v_h = E_h^u \) to get
\[
\|E_h\|_{\varepsilon, +}^2 \lesssim \|E_h\|_{\varepsilon}^2 + \|E_h^u\|_{\varepsilon}^2 \lesssim \|E_h\|_{\varepsilon}^2 + \|E_h\|_{\varepsilon}^2,
\]
by Lemma 3.2. This proves (47). Using (47) in (46), we conclude that \( \|E_h\|_{\varepsilon} \lesssim \|E\|_{\varepsilon, +} \).
Combining with triangle inequality,
\[
\|E\|_{\varepsilon} \leq \|E\|_{\varepsilon} + \|E_h\|_{\varepsilon} \lesssim \|E\|_{\varepsilon, +} \lesssim h \|u\|_{H^2(\Omega)},
\] (49)
where we have applied (28) in the last step. This proves (44).
For the pressure estimate, we begin with triangle inequality and Lemma 4.4:
\[
\nu^{-1}\|p - p_h\|_0 \leq \nu^{-1}\|p - I_Qp\|_0 + \nu^{-1}\|I_Qp - p_h\|_0
\]
\[
\leq \nu^{-1}\|p - I_Qp\|_0 + \sup_{(v_h, \hat{v}_h, \eta_h) \in U_h} \nu^{-1}(\text{div } v_h, I_Qp - p_h).
\]
To bound the numerator of the supremum, we use Lemma 4.1:
\[
\nu^{-1}(\text{div } v_h, I_Qp - p_h) = a_{\text{hdg}}(E; v_h, \hat{v}_h, \eta_h)
\]
\[
\leq \|E\|_\varepsilon \|v_h, \hat{v}_h, \eta_h\|_\varepsilon.
\]
Hence the already proved estimate (49), together with the standard $L^2$ projection error estimates finish the proof of (45). \hfill \Box

5. An MCS formulation with $H(\text{div})$-conforming vorticity

In this section we derive a new mixed method for the approximation of (2), motivated by the weak formulation (7). Let $\sigma_h \in \Sigma_h$ and $(v_h, \hat{v}_h, \eta_h) \in U_h$. Defining
\[
\langle \text{div } \sigma_h; v_h, \hat{v}_h, \eta_h \rangle_{U_h} := (\text{div } \sigma_h, v_h)_{\nabla_T} - ((\sigma_h)_{nn}, (v_h)_{\nabla_T})_{\nabla_T}
\]
\[
- ((\sigma_h)_{nt}, (\hat{v}_h)_n)_{\nabla_T} + (\sigma_h, \kappa(\eta_h))_{\nabla_T},
\]
consider the terms on the right. When $(\sigma_h)_{nt}$ is continuous across element interfaces, the first two terms together realizes the duality pairing introduced in Section 2, namely $\langle \text{div } \sigma, v_h \rangle_{\text{div}}$, per [19, Theorem 3.1]. The third term is used to impose the $nt$-continuity of the viscous stress (and prior works [18, 19, 24] provided enough rationale to employ $nt$-continuous finite elements for viscous stresses). Due to the Dirichlet conditions built into $\hat{\mathcal{V}}_h$ on $\Gamma_D$ (see (8b)), this term is comprised only of integrals over facets in the interior and on $\Gamma_N$, with the latter enforcing $\sigma_{nt} = 0$ in $\Gamma_N$ as demanded by (2f).

Finally, the last term above is used to weakly incorporate the symmetry constraint (2c). This technique of imposing symmetry weakly is widely used in finite elements for linear elasticity [1, 2, 3, 6, 14, 17, 30].

Viewing (7) in terms of $\langle \text{div } \cdot, \cdot \rangle_{U_h}$, we are led to the following mixed method: find $(u_h, \hat{u}_h, \omega_h) \in U_h$ and $(\sigma_h, p_h) \in (\Sigma_h \times Q_h)$ satisfying
\[
\nu^{-1}(\sigma_h, \tau_h) + \langle \text{div } \tau_h; u_h, \hat{u}_h, \omega_h \rangle_{U_h} = 0,
\]
\[
-\langle \text{div } \sigma_h; v_h, \hat{v}_h, \eta_h \rangle_{U_h} - (\text{div } v_h, p_h) + c(\omega_h, \eta_h) = (f, v_h),
\]
\[
-\langle \text{div } u_h, q_h \rangle = 0,
\]
for all $\tau_h \in \Sigma_h$, $(v_h, \hat{v}_h, \eta_h) \in U_h$, and $q_h \in Q_h$, with the stabilizing bilinear form $c(\omega_h, \eta_h) := \nu h^2(\text{div } \omega_h, \text{div } \eta_h)_\Omega$. Note that since $\omega_h$ approximates the vorticity $\omega = \text{curl}(u)$, we have $\text{div } \omega = 0$, so $c(\cdot, \cdot)$ is a consistent addition. Although the formulation (51) is very similar to the formulations from [18] and [19], note the following differences:

First, while the $nt$-continuity of viscous stresses was built into the spaces in [18, 19], now it is incorporated as an equation of the method by the well-known hybridization technique. Second, although we use the same local stress finite element space as in [18], we use the weak symmetric setting from [19]. In the latter, the Lagrange multiplier for the weak symmetry constraint was given by an element-wise discontinuous approximation, whereas here it is in the $\text{div}$-conforming $W_h$. 

5.1. Stability of the MCS method. From the terms in (51), we anticipate that the norms $\| \cdot \|_{U_h}$ and $\| \cdot \|_{e}$ are more natural for the analysis of the MCS method (in contrast to the HDG method). The latter appears in the next lemma.

**Lemma 5.1** (Continuity of MCS formulation). The bilinear forms in (51) are continuous in the sense that for all $\sigma_h, \tau_h \in \Sigma_h$, $p_h \in Q_h$, $\eta_h \in W_h$ and $(u_h, \hat{u}_h, \omega_h) \in U_h$, in addition to the obvious estimates

$$v^{-1}(\sigma_h, \tau_h) \lesssim v^{-1/2}\|\sigma_h\|_0 v^{-1/2}\|\tau_h\|_0,$$

and $c(\omega_h, \eta_h) \lesssim v h^2 \|\div \omega_h\|_0 \|\div \eta_h\|_0$,

the following estimates hold:

$$\langle \div u_h, p_h \rangle \lesssim \|u_h, \hat{u}_h, \omega_h\|_e \|p_h\|_0, \quad (52a)$$

$$\langle \div \sigma_h; u_h, \hat{u}_h, \omega_h \rangle_{U_h} \lesssim \|\sigma_h\|_0 \|u_h, \hat{u}_h, \omega_h\|_e. \quad (52b)$$

**Proof.** Inequality (52a) is proved just like (39). To prove (52b), let us first note an equivalent and more compact form of $\langle \div \sigma_h; v_h, \hat{v}_h, \eta_h \rangle_{U_h}$ obtained by integrating (50) by parts (see e.g., [19, eq. (3.11)]), namely

$$\langle \div \sigma_h; v_h, \hat{v}_h, \eta_h \rangle_{U_h} = -\langle \sigma_h, \nabla v_h - \kappa(\eta_h) \rangle_T + \langle \sigma_h \rangle_{nt} \langle v_h - \hat{v}_h \rangle_T. \quad (53)$$

Using (53), the fact that $\sigma_h$ is trace-free, the Cauchy-Schwarz inequality, and the following estimate (which follows by a local scaling argument using a specific mapping mentioned in the beginning of §3),

$$h^{1/2}\|\langle \sigma_h \rangle_{nt} \|_{\partial T} \lesssim \|\sigma_h\|_T, \quad (54)$$

we get

$$\langle \div \sigma_h; u_h, \hat{u}_h, \omega_h \rangle_{U_h} \lesssim \|\sigma_h\|_0 \left( \|\operatorname{div} \nabla u_h - \kappa(\omega_h)\|_T^2 + h^{-1} \|\Pi^0(u_h - \hat{u}_h)\|_{\partial T}^2 \right)^{1/2}$$

$$\lesssim \|\sigma_h\|_0 \left( \|u_h, \hat{u}_h, \omega_h\|_{U_h} + h^2 \|\div \omega_h\|_T^2 \right)^{1/2},$$

where the last inequality is due to the same argument as in (23). Thus (52b) follows from Lemma 3.4. □

**Lemma 5.2.** For any $(u_h, \hat{u}_h, \omega_h) \in U_h$ there exists a $(\tau_h, q_h) \in \Sigma_h \times Q_h$ satisfying

$$\|\tau_h\|_0 + \|q_h\|_0 \lesssim \|u_h, \hat{u}_h, \omega_h\|_{U_h} + \|\div u_h\|_0. \quad (55)$$

$$\langle \div \tau_h; u_h, \hat{u}_h, \omega_h \rangle_{U_h} - \langle \div u_h, q_h \rangle \gtrsim \|u_h, \hat{u}_h, \omega_h\|_{U_h} + \|\div u_h\|_0^2. \quad (56)$$

**Proof.** For each element $T \in \mathcal{T}$ and each facet $F \subset \partial T$, there are matrix fields $S_0^F$, $S_1^F$, supported on $T$, with the following properties: on $T$, both $S_0^F$, $S_1^F$ are constant matrices in $\mathbb{D}$, their boundary trace $(S_i^F)_{nt=F}$, for $i \in \{0, 1\}$, are constant unit-length vector fields on $F$ that form a basis for the tangent space $n^F_T$, and $(S_i^F)_{nt=F}$ vanishes on all other facets $F' \neq F$ in $\mathcal{F}_h$. Such matrix fields are exhibited in [18, Lemma 5.1]. Given any $(u_h, \hat{u}_h, \omega_h) \in U_h$, set

$$\tau_h^0 := \sum_{T \in \mathcal{T}} \sum_{F \subset \partial T} \sum_{i \in \{0, 1\}} -(S_i^F : \Pi^0 \operatorname{dev}(\nabla u_h - \kappa(\omega_h))) \lambda^F S_i^F,$$

$$\tau_h^1 := \sum_{T \in \mathcal{T}} \sum_{F \subset \partial T} \sum_{i \in \{0, 1\}} \frac{1}{\sqrt{h}} \Pi^0(\hat{u}_h - u_h)_t S_i^F,$$

where $\lambda^F$ is the linear barycentric coordinate function associated to the vertex opposite to the facet $F$. Since $\lambda^F S_i^F$ has a vanishing $nt$-trace and $\Pi^0 \operatorname{dev}(\nabla u_h - \kappa(\omega_h)) \in \mathbb{D}$, we
see that \( \tau_h = \gamma_0 \sigma_h^0 + \gamma_1 \sigma_h^1 \), for any \( \gamma_0, \gamma_1 \in \mathbb{R} \), is an element of \( \Sigma_h \). Also set \( q_h = -\text{div} \ u_h \), so that \(-\langle \text{div} \ u_h, q_h \rangle = \| \text{div} \ u_h \|_0^2 \). For these choices, (55) obviously holds as long as \( \gamma_i \) is chosen independent of \( h \) and \( \nu \). Indeed, such \( \gamma_i \) can be chosen to also ensure that
\[
\langle \text{div} \ \tau_h; u_h, \hat{u}_h, \omega_h \rangle_{U_h} \geq \| u_h, \hat{u}_h, \omega_h \|_{U_h}^2,
\]
so that (56) also holds. This follows from an argument which (we omit and) is similar to that detailed in [19, Lemma 6.5], proceeding simply by appropriately combining Young and Cauchy-Schwarz inequalities.

The combined bilinear form of the MCS method (51) is given by
\[
B(\sigma_h, u_h, \hat{u}_h, \omega_h, p_h; \tau_h, v_h, \hat{v}_h, \eta_h, q_h) := \nu^{-1}(\sigma_h, \tau_h) + \langle \text{div} \ \tau_h; u_h, \hat{u}_h, \omega_h \rangle_{U_h}
\]
\[
- \langle \text{div} \ \sigma_h; v_h, \hat{v}_h, \eta_h \rangle_{U_h}
\]
\[
- \langle \text{div} \ u_h, q_h \rangle - (p_h, \text{div} \ v_h) + c(\omega_h, \eta_h).
\]

Define a norm on the product space \( S_h = \Sigma_h \times V_h \times \hat{V}_h \times W_h \times Q_h \) by
\[
\| \sigma_h, u_h, \hat{u}_h, \omega_h, p_h \|_{S_h} := \nu^{-1/2}(\| \sigma_h \|_0 + \| p_h \|_0) + \nu^{1/2} \| u_h, \hat{u}_h, \omega_h \|_{L^2}.
\]

**Lemma 5.3** (Inf-sup condition for MCS method). For any \( r = (\sigma_h, u_h, \hat{u}_h, \omega_h, p_h) \in S_h \), be arbitrary, there exists an \( s \in S_h \) such that
\[
B(r; s) \geq \| r \|_{S_h}^2, \quad \text{and}
\]
\[
\| s \|_{S_h} \leq \| r \|_{S_h}.
\]

**Proof.** We will find the required \( s \) as a sum of three terms, each in \( S_h \), and each depending on the given \( r \). The first term is set using \( s^* = (\sigma_h, u_h, \hat{u}_h, \omega_h, -p_h) \), for which we obviously have
\[
B(r, s^*) = \nu^{-1}(\sigma_h, \nu \tau_h) + \nu \langle \text{div} \ \tau_h; u_h, \hat{u}_h, \omega_h \rangle_{U_h} - \nu \langle \text{div} \ u_h, q_h \rangle
\]
\[
\geq (\sigma_h, \tau_h) + \nu \left( \| u_h, \hat{u}_h, \omega_h \|_{U_h}^2 + \| \text{div} \ u_h \|_0^2 \right),
\]
\[
\| s^* \|_{S_h} \leq \nu \| r \|_{S_h}.
\]

The second term is \( \tilde{s} = (\nu \tau_h, 0, 0, \nu q_h) \in S_h \), where \( \tau_h \in \Sigma_h \) and \( q_h \in Q_h \) are as in Lemma 5.2 obtained using the given components \( u_h, \hat{u}_h, \omega_h \) of \( r \). The lemma gives some \( \tilde{C} > 0 \) such that
\[
B(r; \tilde{s}) = \nu^{-1}(\sigma_h, \nu \tau_h) + \nu \langle \text{div} \ \tau_h; u_h, \hat{u}_h, \omega_h \rangle_{U_h} - \nu \langle \text{div} \ u_h, q_h \rangle
\]
\[
\geq (\sigma_h, \tau_h) + \nu \left( \| u_h, \hat{u}_h, \omega_h \|_{U_h}^2 + \| \text{div} \ u_h \|_0^2 \right),
\]
\[
\| \tilde{s} \|_{S_h}^2 = \nu^{-1}(\| \nu \tau_h \|_0^2 + \| \nu q_h \|_0^2) \leq \tilde{C} \nu \left( \| u_h, \hat{u}_h, \omega_h \|_{U_h}^2 + \| \text{div} \ u_h \|_0^2 \right).
\]

The third term is \( s^\Delta = (0, -\nu^{-1} v_h, -\nu^{-1} \hat{v}_h, -\nu^{-1} \eta_h, 0) \in S_h \) where \((v_h, \hat{v}_h, \eta_h) \in U_h \) is as in Lemma 4.4 obtained using the given component \( p_h \) of \( r \). The lemma implies that \( \text{div} \ v_h = p_h \) and
\[
B(r; s^\Delta) = \nu^{-1}(\| p_h \|_0^2 - \nu^{-1}(\| \sigma_h \|_{U_h} \| v_h, \hat{v}_h, \eta_h \|_{U_h}) + \nu^{-1} \| c(\omega_h, \eta_h) \|_0^2
\]
\[
\| s^\Delta \|_{S_h}^2 = \nu \| \nu^{-1} v_h, \nu^{-1} \hat{v}_h, \nu^{-1} \eta_h \|_0^2 \leq \nu^{-1} \| p_h \|_0^2.
\]

Note that to obtain the last inequality, we have also used Lemma 3.4.
Now letting $\beta > 0$, a constant yet to be chosen, put $s = \beta s^* + \tilde{s} + s^\Delta$. Then, combining (59a), (60a) and (61a),

$$B(r; s) \geq \frac{\beta}{\nu} \|\sigma_h\|_0^2 + \beta \nu h^2 \|\nabla \omega_h\|_0^2 + \nu \|u_h, \hat{u}_h, \omega_h\|_{U_h}^2$$

$$+ \nu \|\nabla u_h\|_0^2 + \frac{1}{\nu} \|p_h\|_0^2 - (\rho_1 + \rho_2 + \rho_3),$$

where $\rho_1 = (\sigma_h, \tau_h), \rho_2 = -\nu^{-1} \langle \nabla \sigma_h; v_h, \hat{v}_h, \eta_h \rangle_{U_h}, \rho_3 = \nu^{-1} c(\omega_h, \eta_h)$. By (60b) and Young’s inequality,

$$\rho_1 \leq \frac{\tilde{C}}{2\nu} \|\sigma_h\|_0^2 + \frac{1}{2} \left( \|u_h, \hat{u}_h, \omega_h\|_{U_h}^2 + \|\nabla u_h\|_0^2 \right).$$

To bound $\rho_2$, note that by Lemma 5.1, $\rho_2 \leq \nu^{-1} \|\sigma_h\|_0 \|v_h, \hat{v}_h, \eta_h\|_{\mathbb{E}}$, so by (61b), there is a $C^\Delta > 0$ such that $\rho_2 \leq \nu^{-1/2} \|\sigma_h\|_0 \left( \frac{1}{2} C^\Delta \nu^{-1} \|p_h\|_0^2 \right)^{1/2}$. Thus

$$\rho_2 \leq \frac{C^\Delta}{2\nu} \|\sigma_h\|_0^2 + \frac{1}{4\nu} \|p_h\|_0^2.$$  

To bound $\rho_3$, we recall from Lemma 3.4 that $h \|\nabla \eta_h\|_0 \leq \|v_h, \hat{v}_h, \eta_h\|_{\mathbb{E}}$. Hence by (61b), there is a $C' > 0$ such that $\rho_3 \leq (\nu^{1/2} h \|\nabla \omega_h\|_0) \left( \frac{1}{2} C' \nu^{-1} \|p_h\|_0^2 \right)^{1/2}$, so

$$\rho_3 \leq \frac{C' \nu}{2} h^2 \|\nabla \omega_h\|_0^2 + \frac{1}{4\nu} \|p_h\|_0^2.$$  

Using these estimates for $\rho_i$ in (62),

$$B(r; s) \geq \frac{2\beta - (\tilde{C} + C^\Delta)}{2\nu} \|\sigma_h\|_0^2 + \frac{2\beta - C'}{2} \nu h^2 \|\nabla \omega_h\|_0^2$$

$$+ \frac{\nu}{2} \|u_h, \hat{u}_h, \omega_h\|_{U_h}^2 + \frac{\nu}{2} \|\nabla u_h\|_0^2 + \frac{1}{2\nu} \|p_h\|_0^2.$$  

Since $\tilde{C}, C^\Delta$ and $C'$ are mesh-independent constants, choosing $\beta > \max(\tilde{C} + C^\Delta, C')/2$ and recalling the norm equivalence of Lemma 3.4, we prove (57). Of course, inequality (58) follows from (59a), (60b), and (61b). \qed

5.2. Pressure robust error analysis of MCS scheme. In addition to the spaces $U_{\text{reg}}$ and $Q_{\text{reg}}$, the a priori error analysis will now also use a stress space with improved regularity, $\Sigma_{\text{reg}} := \Sigma_{\text{sym}} \cap H^1(\mathcal{T}, \mathbb{D})$. Note that the integrals in the terms defining $B(\sigma, u, \hat{u}, \omega, p; \cdot)$ are well-defined for $\sigma \in \Sigma_{\text{reg}}, (u, u_t, \omega) \in U_{\text{reg}}$, and $p \in Q_{\text{reg}}$, so $B(\cdot, \cdot)$ can be extended to such non-discrete arguments.

Lemma 5.4 (Consistency of the MCS method). Assume that the exact solution $(\sigma, u, p)$ of (7) fulfills the regularity assumption $(u, u_t, \omega) \in U_{\text{reg}}$ and $(\sigma, p) \in \Sigma_{\text{reg}} \times Q_{\text{reg}}$, where $\omega = \text{curl}(u)$. Let $(\sigma_h, u_h, \hat{u}_h, \omega_h, p_h) \in S_h$ be the solution of (51) and let $(\tau, v, \hat{v}_h, \eta, q) \in S_h$ be an arbitrary test function. Then

$$B(\sigma - \sigma_h, u - u_h, u_t - \hat{u}_h, \omega - \omega_h, p - p_h; \tau, v, \hat{v}_h, \eta, q_h) = 0.$$  

(63)
Proof. Since \( \sigma \) is symmetric we have that \( \sigma : \kappa(\eta_h) = 0 \). Next, using the regularity assumptions, starting from (53), we get
\[
-\langle \text{div} \sigma; v_h, \eta_h \rangle - \langle \text{div} v_h, p_h \rangle = (\sigma - p I) \nabla v_h \eta_h - \text{div} (\sigma_{nt}, (v_h - \hat{v}_h)_{\varepsilon})_{\varepsilon T} \\
= -\langle \text{div} (\sigma - p I), v_h \rangle - (\sigma_{nt}, (v_h - \hat{v}_h)_{\varepsilon})_{\varepsilon T} + ((\sigma - p I)n, v_h)_{\varepsilon T} \\
= -\langle \text{div} (\sigma - p I), v_h \rangle + (\sigma_{nt}, \hat{v}_h)_{\varepsilon T} - ((\sigma - p I)_{nn}, (v_h)_{\varepsilon})_{\varepsilon T} \\
= -\langle \text{div} (\sigma - p I), v_h \rangle + \int_{\Gamma_E} (\sigma - p I)_{nn}(v_h)_{\varepsilon} - (\sigma_{nt} v_h)_{\varepsilon} d_s \\
= -\langle \text{div} (\sigma - p I), v_h \rangle, \\
\]
where the boundary integral vanished using (2f) given on \( \Gamma_N \). Next, since \( \nu^{-1} \sigma = \varepsilon(u) = \nabla u - \kappa(\omega) \) we have
\[
\nu^{-1}(\sigma, \tau_h) + \langle \text{div} \tau; u, \hat{u}, \omega \rangle_{U_h} \\
= \nu^{-1}(\sigma, \tau_h) - (\tau_h, \nabla u - \kappa(\omega))_{\varepsilon T} + (\tau_{nt}, (u - u_t)_{\varepsilon})_{\varepsilon T} = 0.
\]
The final remaining term in the bilinear form is also zero since \( \langle \text{div} u, q \rangle = 0 \) as the exact solution is divergence free. \( \square \)

**Theorem 5.5** (Error estimate for the MCS method). Assume that the exact solution \((\sigma, u, p)\) of (7) fulfills the regularity assumption \((u, u_t, \omega) \in U_{\text{reg}}\) and \((\sigma, p) \in \Sigma_{\text{reg}} \times Q_{\text{reg}}\), where \( \omega = \text{curl}(u) \). Let \((u_h, \hat{u}_h, \omega_h) \in U_h\) and \((\sigma_h, p_h) \in \Sigma_h \times Q_h\) be the solution of (51). Then we have the pressure robust error estimate
\[
\nu^{-1}\|\sigma - \sigma_h\|_0 + \|u - u_h, u_t - \hat{u}_h, \omega - \omega_h\|_\varepsilon \lesssim h\|u\|_{H^2(\mathcal{T})}. \tag{64}
\]
Furthermore, the pressure error can be bounded by
\[
\nu^{-1}\|p - p_h\|_0 \lesssim h\|u\|_{H^2(\mathcal{T})} + \nu^{-1}\|p\|_{H^1(\mathcal{T})}. \tag{65}
\]

**Proof.** As in the proof of Theorem 4.5, let \( E = (\sigma - \sigma_h, u - u_h, u_t - \hat{u}_h, \omega - \omega_h, p - p_h) \), \( E_h = (I_{\Sigma} \sigma - \sigma_h, I_{\nabla} u - u_h, I_{\nabla} u_t - \hat{u}_h, I_{\nabla} \omega - \omega_h, I_Q p - p_h) \), and let the interpolation error be \( \mathcal{E} = E - E_h \). Now, using Lemma 5.3, choose \( s = (\tau_h, v_h, \hat{v}_h, \eta_h, q_h) \) such that
\[
\|E_h\|_{S_h} \lesssim B(E_h; s).
\]
By the consistency of the MCS formulation (63) we have
\[
B(E_h; s) = B(E - \mathcal{E}; s) = B(\mathcal{E}; s).
\]
Hence, if we prove that
\[
B(\mathcal{E}; s) \lesssim \nu^{1/2}h\|u\|_{H^2(\mathcal{T})}\|s\|_{S_h}, \tag{66}
\]
then \( \|E_h\|_{S_h} \lesssim \nu^{1/2}h\|u\|_{H^2(\mathcal{T})} \), which is enough to yield the stated pressure-independent estimate (64): indeed, letting \( \bar{E} := (\sigma - \sigma_h, u - u_h, u_t - \hat{u}_h, \omega - \omega_h, 0) \), \( \bar{E}_h := (I_{\Sigma} \sigma - \sigma_h, I_{\nabla} u - u_h, I_{\nabla} u_t - \hat{u}_h, I_{\nabla} \omega - \omega_h, 0) \), and \( \bar{\mathcal{E}} = \bar{E} - \bar{E}_h \), we would then have
\[
\|\bar{E}\|_{S_h} \leq \|\bar{\mathcal{E}}\|_{S_h} + \|\bar{E}_h\|_{S_h} \lesssim \|\bar{\mathcal{E}}\|_{S_h} + \|E_h\|_{S_h} \leq \nu^{1/2}h\|u\|_{H^2(\mathcal{T})}, \tag{67}
\]
using the interpolation estimates (28)–(29) to bound \( \| \mathcal{E}_{\text{S}} \| \). Inequality (67) obviously implies (64). Therefore we focus on proving (66) and proceed to separately inspect each term forming its left hand side.

Let \( \mathcal{E}^j \) with \( j \in \{ \sigma, u, \hat{u}, \omega, p \} \) denote the corresponding components of the interpolation error. Then (53) implies

\[
\langle \text{div} \tau_h; \mathcal{E}^u, \mathcal{E}^{\hat{u}}, \mathcal{E}^\omega \rangle = (\tau_h, \kappa(\mathcal{E}^\omega) - \nabla \mathcal{E}^u)_T + ((\tau_h)_nt, (\mathcal{E}^u - \mathcal{E}^{\hat{u}})_t)_{\partial T}.
\]

As \( (\tau_h)_nt \) is constant on each facet, we can insert \( \Pi^0 \) in the last term, so several applications of the Cauchy-Schwarz inequality with \( h^{1/2} \) and \( h^{-1/2} \) weights for the boundary terms yields

\[
\langle \text{div} \tau_h; \mathcal{E}^u, \mathcal{E}^{\hat{u}}, \mathcal{E}^\omega \rangle \lesssim \left( \| \tau_h \|_0 + h^{1/2} \| (\tau_h)_nt \|_{\partial T} \right) \| \mathcal{E}^u, \mathcal{E}^{\hat{u}} \|_{V} + \| \kappa(\mathcal{E}^\omega) \|_0.
\]

where we used (54) again and the interpolation estimate (28) in the last step.

Next consider symmetrically opposite term in \( B \). Since \( \nabla v_h \in P^0(\mathcal{T}) \) and \( \mathcal{E}^\sigma \) is orthogonal to facet-wise and element-wise constant functions (see (26)–(27)), we have \( -(\text{div} \mathcal{E}^\sigma; v_h, \hat{v}_h, \eta_h)_{U_h} = (\mathcal{E}^\sigma, \nabla v_h - \kappa(\eta_h))_T - (\mathcal{E}^\sigma_{nt}, (v_h - \hat{v}_h)_t)_{\partial T} \) \( = -(\mathcal{E}^\sigma, (I - \Pi^0)\kappa(\eta_h))_T - (\mathcal{E}^\sigma_{nt}, (I - \Pi^0)(v_h - \hat{v}_h)_t)_{\partial T} \) \( \lesssim \| \mathcal{E}^\sigma \|_0 \| v_h, \hat{v}_h, \eta_h \| + h^{1/2} \| \mathcal{E}^\sigma_{nt} \|_{\partial T} \| v_h, \hat{v}_h \|_{\nabla}. \)

where on the right hand side of the last inequality, the first term is obtained using (20b) and Lemma 3.4, while the second term is obtained using (48). Thus, the interpolation estimate (29) and Lemma 3.2 imply

\[
\langle \text{div} \mathcal{E}^\sigma; v_h, \hat{v}_h, \eta_h \rangle_{U_h} \lesssim \nu h \| u \|_{H^2(\mathcal{T})} \| v_h, \hat{v}_h, \eta_h \|_\epsilon.
\]

The remaining terms are easy: by Cauchy-Schwarz inequality,

\[
\nu^{-1}(\mathcal{E}^\sigma, \tau_h) \lesssim h \| u \|_{H^2(\mathcal{T})} \| \tau_h \|_0.
\]

and by the definition of \( I_W, I_Q \) and (25),

\[
(\text{div} \mathcal{E}^\omega, \text{div} \eta_h) = 0, \quad (\text{div} \mathcal{E}^u, q_h) = 0, \quad \text{and} \quad (\mathcal{E}^p, \text{div} v_h) = 0,
\]

where the last equation is due to \( \text{div} v_h \in P^0(\mathcal{T}) \). Summing up (68), (69), (70), and (71), we prove (66), and hence (64).

The pressure error estimate (65) follows along the same lines as in the proof of Theorem 4.5. \( \square \)

6. Numerical examples

In this last section we present a simple numerical example to provide a practical illustration of the theoretical asymptotic convergence rates as well as to compare the two new methods we presented. Both methods were implemented within the finite element library NGSolve/Netgen (see [28, 29] and www.ngsolve.org).

The computational domain is given by \( \Omega = (0, 1)^3 \) and the velocity field is driven by the volume force determined by \( f = -\nabla \sigma + \nabla p \) with the exact solution given by

\[
\sigma = \nu \varepsilon(\text{curl}(\psi, \psi, \psi)), \quad \text{and} \quad p := x^5 + y^5 + z^5 - \frac{1}{2}.
\]
Here $\psi := x^2(x-1)^2y^2(y-1)^2z^2(z-1)^2$ defines a given potential and we choose the viscosity $\nu = 10^{-4}$. While this would lend itself to homogenous Dirichlet conditions being prescribed on the whole boundary, as we assume $|\Gamma_N| > 0$ throughout the paper, we instead opt to impose non-homogenous Neumann conditions on $\Gamma_N := \{0\} \times (0,1) \times (0,1)$ and homogenous Dirichlet conditions only on $\Gamma_D := \partial\Omega \setminus \Gamma_N$. Note that this requires the additional source terms $\int_{\Gamma_N} (\sigma_{nn} - p)(v_h)\, ds$ and $\int_{\Gamma_N} \sigma_{nt} v_h \, ds$ to be provided as data for the methods.

**Convergence.** An initial, relatively coarse mesh was generated and then refined multiple times. To be able to solve the problem also on the finer meshes we employed a preconditioned GMRes Krylov space solver with relative tolerance $10^{-14}$. Errors measured in different norms and their estimated order of convergence (eoc) are listed in Table 1 for the HDG method and Table 2 for the MCS method. For the HDG method we chose the stabilization parameter $\alpha = 6$. As predicted by the analysis from Theorem 4.5 and Lemma 5.5, the velocity error measured in the seminorm $\|\varepsilon(u - u_h)\|_0$, the $L^2$-norm of the vorticity, and the pressure errors converge at optimal linear order. Furthermore, for the MCS method, we also observe optimal convergence for the stress error. In addition, we also plotted the $L^2$-norm error of the velocity. From an Aubin-Nitsche argument one may expect a higher order of convergence whenever the dual problem shows enough regularity [4, 18]. Not surprisingly therefore, we observe quadratic convergence for the $L^2$-norm of the velocity error for both methods.

**Condition numbers.** For both HDG and MCS method, after static condensation within the $(u_h, \hat{u}_h, \omega_h)$- or $(\sigma_h, u_h, \hat{u}_h, \omega_h)$-block of the finite element matrix respectively, we obtain a symmetric and positive definite diagonal block, which we simply refer to here as the “$A$”-blocks of the respective methods. (Of course, due to the incompressibility constraint, the entire system is still of saddle point structure.) Both the $A$ blocks have the same non-zero structure and are expected to have condition number $O(h^{-2})$, but they discretize slightly different operators, namely $\varepsilon$ for the HDG method, and $\text{dev}(\varepsilon)$ for the MCS method. As $\varepsilon(u) = \text{dev}(\varepsilon(u)) + \frac{1}{3} \text{div}(u) I$ and the true solution is divergence-free, adding the (consistent) term $\frac{1}{3} \text{div} u_h \text{div} v_h$ to the MCS bilinear form yields an $A$ block that is directly comparable to the one of the HDG method. In Figure 3 we show approximate condition numbers (cond) of said $A$ blocks for some of the meshes used in the previous computations and different values of $\alpha$ in $\alpha^{\text{hdg}}$. We see that in addition to the MCS method not being dependent on any stabilization parameter in the first place, there appears to be no possible choice of $\alpha$ that would make the HDG method’s $A$ block better conditioned than that of the MCS method.
