A Cross Sectional Study to Evaluate Awareness About Hepatitis A & E Among Students in Lahore

Azka Rizvi1, Naveed Ahmed2, Ayesha Naeem1, Waqas Saleem3, Muhammad Ilyas1, Altaf Ahmed4

Abstract

Background: The aim and objectives of the study were to determine the knowledge, attitude and practices among biological and non-biological students regarding Hepatitis A virus (HAV) and Hepatitis E virus (HEV).

Methods: The present study was conducted by the Department of Microbiology, Pakistan kidney & liver institute and research center (PKLI & RC) at University of Veterinary and Animal Sciences (UVAS), Lahore, Pakistan. The study was conducted in November, 2019 to January, 2020. A total of 326 respondents (students) participated in the present study. Respondents filled a pre-tested structured questionnaire. The variables accessed were knowledge of the diseases including etiology, mode of transmission, and prevention and control measures.

Results: Most 81.56% of respondents from biological sciences (B-S) group and 51.70% from non-biological sciences (N-B-S) had awareness about HAV/HEV. Furthermore, 72.06% of respondents from BS group and 13.60% of respondents from NBS group had knowledge about the mode of transmission and spread of HAV and HEV infection. Only 16.20% of students from B-S group were aware about importance of vaccination against HAV/HEV. While a very low prevalence was found about vaccination in N-B-S group that is only 4.76%.

Conclusion: The study shows significance difference in the awareness level among students from biological sciences and non-biological sciences background. Respondents were found to misunderstand the hepatitis A & E infections with hepatitis B & C, which suggests that there is need to spread awareness about the differences in their spread and severity of these infections. Awareness campaigns should be conducted to make people aware of the ways HAV/HEV spreads, its mode of transmission, severity of infection and preventive measures to minimize its spread as well as chances to acquire HAV/HEV infections.

Keywords: Hepatitis A, hepatitis E, knowledge; attitude, practices

Introduction

Viral hepatitis is responsible for causing significant morbidity and mortality every year throughout the world. While it remains self-limiting most of the time but unrecognized and under treated viral hepatitis can lead to chronic hepatitis, cirrhosis, hepatocellular carcinoma, liver failure and even death in immune-compromised (1). Hepatitis A (HAV) and Hepatitis E virus (HEV) are responsible for causing acute viral hepatitis (2). In the past two decades, focus on eliminating hepatitis B and
hepatitis C lead to negligence towards occurrence of HAV and HEV infections. However, the fact that HAV infects 1.4 billion people and HEV infects 20 million people each year resulting in 56000 deaths respectively, requires immediate attention (3). Asymptomatic infection of HAV occurs in children while on the other hand in case of adults and older children there is a wide spectrum of disease ranging from mild to anicteric to fulminant hepatic failure which results in the wild range of morbidity and mortality (4). Though it remains endemic in developing countries like Pakistan but the rate of sero-prevalence is decreasing day by day in developed countries. Both HAV and HEV are transmitted through fecal-oral route (5). HAV spreads through eating and drinking raw and contaminated food while HEV infection is mostly associated with contaminated drinking water and poor sanitation conditions (6).

The virus responsible for causing hepatitis A is a remarkably resistant positive sense, non-enveloped RNA virus belonging to family Picornaviridae in the genus Hepatovirus (3). It has 6 genotypes out of which I, II, and III have been identified as human pathogen (7). In third world countries like Pakistan, because of poor sanitary conditions, there is a continuous increase in HAV infection cases and almost 90% population become infected with the virus during their early childhood. During early childhood there is no or almost very minimum signs of clinical infection and the person develop the lifelong immunity making them immune for the lifetime (8). However, in middle income, economically stable areas where sanitary condition is much more developed, children might escape infection in childhood leading to accumulation of older people who were never exposed to the virus. In case of developed countries, the spread of virus is minimum to none and people only get infected by travelling to disease endemic areas or being exposed to the infected individuals (9). However, people do get infected in industrialized countries by consuming contaminated produce such as tomatoes and berries etc (10). There is no specific treatment for HAV infection and infection can last from few weeks to several months but live attenuated vaccine is available in China. This vaccine has protective effects even after administration of only one dose, 2-weeks post exposure to the virus (2, 11).

Like HAV, HEV is a positive sense non-enveloped RNA virus belonging to the family Hepeviridae in the genus Hepevirus. HEV is the main cause of acute liver failure (ALF) or also called as acute hepatitis. HEV is the most common cause of acute viral hepatitis throughout the world. During an outbreak in the early 1980s, it was discovered in Indian occupied province of Kashmir, when a patient was tested negative for both HAV and HAB. It was called hepatitis “E” virus because of its affiliation with epidemics and enteric mode of transmission (12). HEV has only four genotypes. Genotypes 1 and 2 infects humans only, but genotypes 3 and 4 infect humans along with pigs and many other mammalian species (1). HEV is endemic in many countries of Asia, Africa, Middle East and Central America (6). In developed areas with better sanitation, people rarely get infected and genotype-3 is mostly responsible for the infection because of ingesting raw or undercooked meat of infected animals. In rare cases, HEV infection can get worse and lead to acute live failure or fulminant hepatitis. Which occurs more frequently in pregnant women and out of those women in the second or third trimester, are at greater risk of developing acute liver failure leading to fetal loss and even death. Death of up to 20–25% of pregnant women can occur if they get infected with hepatitis E in third trimester, as they are more prone to getting infected (13). There still isn’t any specific treatment available for HEV but hospitalization is required for people with fulminant hepatitis. Also, ribavirin is proved to be a success in treating immunocompromised patients with chronic hepatitis. In 2011, China made sub-unit vaccine to prevent HEV, made it to the private market but it has not yet been approved in other countries. The vaccine has proved to provide long term immunization for up to 4.5 years (14).

Geographical location of Pakistan suggests that there are chances of occurrence of HEV and HAV infections with non-Pakistani origin i.e. from other Asian countries. Although, about 90% of population becomes infected with these viruses even before reaching the age of 10 years and they remain immune to the infection for the rest of their lives (15, 16). Last year, several cases of hepatitis E have been reported in different districts and cities of Punjab, Pakistan. On April 26th, 2019, it was reported by the local news channel that (8).

Previous studies showed that the incidence of HAV and HEV was more in under-developed areas with poor sanitation and low socio-economic status as compared to areas with developed and more educated population inhabiting it (17, 18). So, present study was...
A Cross Sectional Study to Evaluate Awareness About Hepatitis A & E Among Students in Lahore

designed to evaluate the prevalence and relative awareness of population with biological science background and population with non-biological sciences background. Aim of the study was to better understand the impact and role of education system and awareness campaigns among biological sciences and non-biological sciences students. So that better campaigns can be conducted to raise awareness regarding hepatitis A and E in order to help decrease its incidence.

Methodology

Study design

The present cross-sectional survey study was conducted by the Department of Microbiology, Pakistan kidney & liver institute and research center (PKLI & RC) at University of Veterinary and Animal Sciences (UVAS), Lahore, Pakistan. The study was conducted in November, 2019 to January, 2020. A questionnaire consisting of 18 multiple-choice questions. It was designed to evaluate respondents’ perception and understanding about hepatitis A (HAV) and hepatitis E (HEV) infection. The questionnaire was divided into three parts. The first section addressed demographics which included: age, gender, marital status, educational level. Second part included basic knowledge about HAV and HEV including its mode of transmission, health status of the respondents, family history of HAV or HEV infections, including their practices towards HAV & HEV screening and vaccination. The respondents were requested to recall whether they had HAV or HEV testing, the results of the blood test, and whether they had received HAV or HEV vaccination. The questionnaire was developed in English. In this study, students from science and non-science departments, healthcare professionals (DVM) categorizing them into biological sciences (B-S) and non-biological sciences (N-B-S) groups. Biological science includes students from Department of Food, Nutrition & Dietetics, Department of Biotechnology & Genetic Engineering, Department of Microbiology. Department of Medical Laboratory Sciences and Faculty of Veterinary Sciences. While, students from Non-Biological sciences includes students from UVAS Business School (UBS).

Table 1. Frequency distribution of socio demographic variables of study participants (n=326).

| Variables       | Description   | Number of Participants | %   |
|-----------------|---------------|------------------------|-----|
| Age             | <18           | 76                     | 23.31|
|                 | 18-25         | 233                    | 71.47|
|                 | 26-35         | 12                     | 3.68 |
|                 | 36-45         | 5                      | 1.53 |
| Gender          | Male          | 133                    | 40.79|
|                 | Female        | 193                    | 59.20|
| Marital status  | Single        | 294                    | 90.18|
|                 | Married       | 32                     | 9.81 |
| Education       | Graduation    | 249                    | 76.38|
|                 | Post-Graduation| 77                   | 23.61|
| Departments     | Biological sciences | 179    | 54.90|
|                 | Non-Biological sciences | 147  | 45.09|

Data collection

Questionnaires were distributed among personnel who were volunteered to participate in the study. An informed consent was taken prior to collect the data. Data was collected from a total of 326 respondents. Throughout this process, close physical monitoring was done to ensure the quality of data and to omit any discrepancies. Respondents were requested to answer all the question with the best of their knowledge and understanding. After the collection of data, the data was put in Microsoft Excel file and analyzed further for statistical analysis.

Results

Awareness about HAV and HEV infections
81.56% of Biological Science students and 51.70% of Non-Biological Science students had knowledge about HAV and HEV infections. Furthermore, 48% of B-S group said that they know about HAV/HEV infection through reading a research article, 25% through television and 8% through reading newspaper. On the other hand, 33% of N-B-S group learned about these infections through television, 21% through newspaper and 17% through research article.
Awareness about spread and transmission of HAV and HEV infection
72.06% of respondents from B-S group and 13.60% of respondents from N-B-S group had knowledge about the mode of transmission and spread of HAV and HEV infection.

Awareness about personal hygiene
Around 90-95% of the respondents from both groups were clear that improved personal hygiene, washing hands before and after eating, and drinking filtered/boiled water prevents from acquiring HAV/HEV infection.

Awareness about use of antibiotics
When asked if antibiotics can be used to treat HAV/HEV infection, 59.21% of respondents from B-S group said “No” which means rest of the 41% of respondents believe that in viral infection, antibiotics can be used. While in N-B-S group 63% of respondents’ response was in favor of using antibiotics in HAV/HEV infections and only 38% of them said that antibiotics cannot be used in HAV/HEV infections.

Table 2. Vaccination status of study respondents.

| VACCINATION STATUS OF STUDY PARTICIPANTS | Answers |
|-----------------------------------------|---------|
|                                        | YES     | NO      |
| BIOLOGICAL SCIENCE STUDENTS             |          |         |
| Vaccination against Hepatitis A         | FREQUENCY | 41 | 138 |
|                                        | PERCENTAGE | 22.90 | 77.09 |
| Vaccination against Hepatitis E         | FREQUENCY | 47 | 132 |
|                                        | PERCENTAGE | 26.25 | 73.74 |
| TOTAL                                   | 179      |         |
| NON-BIOLOGICAL SCIENCE STUDENTS         |          |         |
| Vaccination against Hepatitis A         | FREQUENCY | 28 | 119 |
|                                        | PERCENTAGE | 19.04 | 80.95 |
| Vaccination against Hepatitis E         | FREQUENCY | 26 | 121 |
|                                        | PERCENTAGE | 17.68 | 82.31 |
| TOTAL                                   | 147      |         |

Vaccination status of study participants
When inquired about the vaccination (HAV and HEV) status, it was revealed that from B-S group only 22.90% of respondents were vaccinated against HAV. While, 77% of respondents were not vaccinated against HAV. 26.25% of respondents from B-S group were found vaccinated against HEV, while the other 73.74% were not vaccinated yet.
In Non-Biological science group, the vaccination status of respondents against HAV and HEV was 19.04% and 17.68% respectively.

Table 3. Laboratory testing statuses for HAV and HEV among study participants.

| LABORATORY TESTING STATUS OF STUDY PARTICIPANTS | Answers |
|-----------------------------------------------|---------|
|                                              | YES | NO |
| BIOLICAL SCIENCE STUDENTS                    |      |    |
| Testing for Hepatitis A                       | FREQUENCY | 66 | 113 |
|                                              | PERCENTAGE | 36.87 | 63.12 |
| Testing for Hepatitis E                       | FREQUENCY | 21 | 158 |
|                                              | PERCENTAGE | 11.73 | 88.26 |
| TOTAL                                         | 179 |    |
| NON-BIOLICAL SCIENCE STUDENTS                 |      |    |
| Testing for Hepatitis A                       | FREQUENCY | 41 | 106 |
|                                              | PERCENTAGE | 27.89 | 72.10 |
| Testing for Hepatitis E                       | FREQUENCY | 17 | 130 |
|                                              | PERCENTAGE | 11.56 | 88.43 |
| TOTAL                                         | 147 |    |

Awareness about severity of infection-to cause liver failure
When inquired about the fact that (HAV and HEV) cause liver failure, it was revealed that only 46.36% of respondents from B-S group and 32.65% of N-B-S group were aware of the fact that HAV and HEV cause hepatic failure. While, on the other hand, 54% of respondents from B-S group and 68% of N-B-S group were uncertain about the liver failure caused by HAV and HEV.

Table 4. Percentage distributions of HAV/HEV awareness amongst respondents.

| Statements of Awareness | Biological Sciences Students | Non-Biological Sciences Students |
|-------------------------|------------------------------|---------------------------------|
| Awareness               | FREQUENCY | 146 | 76 |
A Cross Sectional Study to Evaluate Awareness About Hepatitis A & E Among Students in Lahore

* Inadequate knowledge when correct response was by less than 50% of the study participants to a particular question. ** Moderate knowledge when correct response for a particular question was by 50%-80% of the study participants. *** Adequate knowledge when more than 80% participants responded correctly to a particular question.

**Discussion**

Around 90% of population of Pakistan is infected with HAV before the age of 10 years due to poor sanitary conditions (15, 19, 20). 50-60% of cases of acute viral hepatitis are reported in pediatric population of Pakistan (12). and only 5.1 to 6.4% of adults are diagnosed with HAV. By the age of 5, almost 96% of Pakistani population is exposed to HAV while 98-100% of adult population becomes exposed to HAV. Hepatitis E virus (HEV) is the causative agent of hepatitis E, and is endemic in Pakistan and it transmitted through fecal oral route. It occurs mostly during the rainy season when there are high chances of floods and there is mixing of drinking water with sewage water and people have communal life style (12). Knowledge and understanding about HAV/HEV is critical for general public of Pakistan because of increasing number of incidents (21).

Among viral hepatitis, acute viral hepatitis caused by HAV and HEV are at the top in Pakistan with HAV accounting for up to 50-60% of all the cases, in children (12). While HEV remains endemic in Pakistan affecting younger kids and adult population (5). Pakistan is an under-developed country with health and literacy rate at the bottom of the mark. As hepatitis has become a serious problem of Pakistan (8), there is a need to run awareness campaigns to minimize the incidence of HAV and HEV.

In the present study it was observed that at about 81.56% of the students from biological sciences group had heard about HAV/HEV infections while 72.06% of them had knowledge about its mode of transmission. 51.70% of students from non-biological sciences group heard about HAV/HEV infection and only 13.60% of them knew how these infections transmit. These results similar to the results obtained from the research done in 2016 to evaluate the level of awareness level among dental students and general public (22). Similarly, a study conducted among dental students and general public regarding hepatitis B awareness in 2011, also reported the difference in awareness level of general population (including people from non-biological sciences background) and dental students as dental students were comparatively more aware than the general population. This might be due to the field related awareness programs, educational sessions, seminars and other field related requirements which made dental students aware of the hepatitis B infection (22). This finding also highlights the need to conduct more campaigns and awareness sessions for not just people from biological and medical sciences but general public as well. Students were found to take hepatitis A & E for hepatitis B & C and were unable to clearly identify their mode of transmission, severity of infection and consequences of not considering it as a serious health problem. Similar case of inability to recognize and differentiate between hepatitis B and A was reported in a study conducted in Hong Kong back in 2010 (23).

The study shows significance difference in the awareness level among people from biological sciences and non-biological sciences background.
People were found to mistake spread of hepatitis A & E infections with hepatitis B & C, which suggests that there is need to spread awareness about the differences in their spread and severity of these infections. These results were similar to the survey conducted in Hong Kong about awareness of hepatitis B infection in public where people found to mistake hepatitis B for hepatitis A (23).

Similar to low awareness about the spread of HBV/HCV infections (23), Covid-19 (24) there is need to educate people about HAV/HEV as well. Although only 20% of B-S group had a family history of HAV/HEV, 22.90% of them had vaccination against it HAV and 26.25 had vaccination against HEV. But the trend is different in N-B-S group as only 19.04% of them had vaccination against HAV and 17.68 were vaccinated against HEV, while 28% of them had family history of the infection. This shows that people from biological science background were more aware of the fact that they should be vaccinated to prevent this disease. Overall knowledge about these infections of both groups was sufficient, but the knowledge about the risk factors was very low.

Almost 70% of the respondents from both groups were unaware of the fact that screening of these infections is critical in preventing the disease as only 11.73% from B-S and 11.56% from N-B-S group got tested for HAV, while in HAV the testing rate was 36.87% and 27.89% respectively. However, 68% from B-S and 42% from N-B-S group were aware of the fact that HAV/HEV can cause liver failure as well. Screening and vaccination behaviors are interlinked and are associated with respondents’ educational level and occupation as demonstrated in awareness survey conducted in Hong Kong (23).

**Study Limitations**

For our study design we used small number of students belonging to one institute only, in contrast to more students studying at different institutes in order to generalize the results. This was a single institute based study; therefore, the results cannot be generalized.

**Conclusion**

This survey highlights the need to spread awareness among students of Pakistan about HAV/HEV infection. Awareness campaigns should be conducted to make people aware of the ways HAV/HEV spreads, its mode of transmission, severity of infection and preventive measures to minimize its spread as well as chances to acquire HAV/HEV infections. It is important to understand the need to educate people, especially from lower socio-economic status as they might not know about these infections and how its spreads.
