A Raman spectroscopic investigation of speciation in La$_2$(SO$_4$)$_3$(aq)†

Wolfram W. Rudolph* and Gert Irmer

Raman spectroscopic measurements have been made of aqueous solutions of La(ClO$_4$)$_3$, La$_2$(SO$_4$)$_3$, and Na$_2$SO$_4$ in water and heavy water, in the terahertz frequency region (40–1400 cm$^{-1}$) and down to low concentrations (0.000263 mol L$^{-1}$). Temperature dependent measurements of a 0.0098 mol L$^{-1}$ La$_2$(SO$_4$)$_3$ solution have been carried out from 23–98 °C. In solutions of La(ClO$_4$)$_3$ with water and heavy water, the [La(OH$_2$)$_9$]$_3^+$ and [La(OD$_2$)$_9$]$_3^+$ have been characterized and a weak, strongly polarized band observed at 343 cm$^{-1}$ and 326 cm$^{-1}$ respectively assigned to the $v_1$ LaO$_9$ mode, the breathing mode of the clusters. In La$_2$(SO$_4$)$_3$(aq), in addition to the $v_1$SO$_4^{2-}$ mode at 980 cm$^{-1}$, a pronounced band component at 991 cm$^{-1}$ has been assigned to an inner-sphere complex (ISC) and a similar $v_1$SO$_4^{2-}$ band contour has been observed in La$_2$(SO$_4$)$_3$ solutions in D$_2$O. Sulfate may act as a monodentate ligand. Conformation of this assignment is provided by the component at 312 cm$^{-1}$ of the [La(OH$_2$)$_9$OSO$_3$]$^+$ species in addition to the band at 343 cm$^{-1}$ for the fully hydrated cluster, [La(OH$_2$)$_9$]$^{3+}$. After subtraction of the component of the ISC at 991 cm$^{-1}$, the $v_1$SO$_4^{2-}$ band in La$_2$(SO$_4$)$_3$(aq) showed systematic differences from that in Na$_2$SO$_4$(aq). This is consistent with a $v_1$SO$_4^{2-}$ band at 983.3 cm$^{-1}$ that can be assigned to the existence of an outer-sphere complex (OSCs). The observed change of the degree of sulfato-complex formation with dilution reflects the stepwise sulfato-complex formation. A $K_2$ value has been determined at 0.9 of the equilibrium between OSC and ISC. Temperature dependent measurements on a dilute La$_2$(SO$_4$)$_3$ solution have shown that the concentration of the La$^{3+}$ sulfato-complex rises with increasing temperature while at the same time the concentration of the ‘free’ sulfate diminished. The sulfato-complex formation is an endothermic process absorbing heat with increasing temperature. The following thermodynamic parameters for the rate determining equilibrium, [La(OH$_2$)$_9$SO$_4^{2-}$ $\leftrightarrow$ [LaOSO$_3$]$^+$ has been determined: $\Delta H^0 = 18.6$ kJ mol$^{-1}$ and $\Delta S^0 = 62.1$ J mol$^{-1}$ K$^{-1}$.

1. Introduction

Lanthanum sulfate enneahydrate, La$_2$(SO$_4$)$_3$·9H$_2$O, is the most common hydrate of lanthanum sulfate, La$_2$(SO$_4$)$_3$·nH$_2$O ($n = 1$–9)$^{1-3}$ and is the only stable hydrate in contact with its solution between 0° and 100°. La$_2$(SO$_4$)$_3$ is sparingly soluble at room temperature and the solubility diminishes with temperature. Lanthanum exists in aqueous solution exclusively in the trivalent state and the La$^{3+}$ ion is strongly hydrated due to its high charge to radius ratio. The coordination number (CN) in the primary hydration shell for La$^{3+}$ in aqueous solution has been determined at nine (data in Table 1, ref. 4). The water molecules of the nonhydrate results in a hydration structure of a tricapped trigonal prism (TPP) with $D_3$ symmetry.$^3$ The O-atoms of the three waters in the equatorial plane (capping position) are separated from the cation by a bond distance of 2.64 Å, while six water molecules at the vertices of the trigonal prism have a La-O bond distance of 2.515 Å.$^{3,6}$ A recent Raman spectroscopic investigation revealed that in concentrated La(ClO$_4$)$_3$(aq) ion pairs are formed while in dilute solutions the undisturbed [La(H$_2$O)$_9$]$^{3+}$ species exist.

This study has been undertaken to characterize the species formed in aqueous La$^{3+}$–sulfate solutions over a very broad concentration range and at elevated temperatures. Sulfato-complex formation has been characterized in solutions on a variety of divalent and trivalent metal sulfates$^{7-22}$ and the question arises whether these complexes also occur with La$^{3+}$(aq). The investigation of La$_2$(SO$_4$)$_3$ solutions proved to be especially challenging because lanthanum sulfate is only sparingly soluble in water and the salt shows a retrograde solubility with temperature increase. The study on the aqueous La$_2$(SO$_4$)$_3$ is the first Raman experimental investigation one this dilute system. The following aqueous systems have been measured using Raman spectroscopy at 23 °C: La(ClO$_4$)$_3$, La$_2$(SO$_4$)$_3$, and Na$_2$SO$_4$. Specifically, we have been interested in the vibrational characterization of the La$^{3+}$–aqua stretching band at low

concentration and the possible formation of ion pairs/complexes between La$^{3+}$ and sulfate. Dilute Na$_2$SO$_4$ solutions have been measured to characterize the sulfate modes free of sulfato-complex species. A La$_2$(SO$_4$)$_3$ solution at 0.0098 mol L$^{-1}$ has been measured from 23 $^\circ$C to 98 $^\circ$C in order to characterize the sulfato-complex formation as a function of temperature. Thermodynamic parameters such as enthalpy and entropy of the sulfato-complex formation have been determined from the measured $K_i$ values as a function of temperature.

2. Experimental details

2.1. Preparation of solutions

Lanthanum perchlorate solutions were prepared from La$_2$O$_3$ (Sigma-Aldrich, 99.9%) and HClO$_4$ in a beaker until all oxide dissolved. The lanthanum ion content was analysed by complexometric titration.$^{13}$ The solution density was determined with a pycnometer at 23 $^\circ$C and the molar ratios water per salt were calculated ($R_w$ values). A La(ClO$_4$)$_3$ stock solution was prepared at 2.488 mol L$^{-1}$ ($R_w = 81.54$) and 0.498 mol L$^{-1}$ ($R_w = 103.43$) and 0.249 mol L$^{-1}$ ($R_w = 213.75$). The solutions were analyzed for dissolved chloride with a 5% AgNO$_3$ solution. The absence of a white AgCl precipitate proved that the stock solution was free of Cl$^-$.

Lanthanum sulfate is only sparingly soluble in water. A 0.0376 mol L$^{-1}$ La$_2$(SO$_4$)$_3$ stock solution (0.0378, mol kg$^{-1}$) was prepared from La$_2$(SO$_4$)$_3$·9H$_2$O and was used to further prepare dilute solutions. The solution density of the stock solution and its La$^{3+}$ were determined as described above. The pH of the stock solution was determined with a glass electrode equal to 5.52. Nine solutions were prepared from this stock solution: 0.0302 mol L$^{-1}$, 0.0189 mol L$^{-1}$, 0.0093 mol L$^{-1}$, 0.00754 mol L$^{-1}$, 0.00606 mol L$^{-1}$, 0.00377 mol L$^{-1}$, 0.00189 mol L$^{-1}$, 0.00121 mol L$^{-1}$, 0.00094 mol L$^{-1}$ and 0.00026 mol L$^{-1}$. The lanthanum ion content was analysed by complexometric titration and the solution density was determined with a 5.000 mL pycnometer at 23 $^\circ$C.

2.2. Spectroscopic measurements

Raman spectra were measured in the macro chamber of the T 64000 Raman spectrometer from Jobin Yvon in a 90$^\circ$ scattering geometry at 23 $^\circ$C. These measurements have been described elsewhere in detail.$^{15,16}$ Briefly, the spectra were excited with the 514.5 nm line of an Ar$^+$ laser at a power level of 1100 mW at the sample. After passing the spectrometer in subtractive mode, with gratings of 1800 grooves per mm, the scattered light was detected with a cooled CCD detector. $I_{VV}$ and $I_{VH}$ spectra were obtained by fixed polarisation of the laser beam and the polariser at 90$^\circ$ between the sample and the entrance slit to give the scattering geometries:

\[ I_{VV} = I(1[YZ]X) = 45\alpha^2 + 4\gamma^2 \]  
\[ I_{VH} = I(1[Y]Z)X = 3\gamma^2. \]

The isotropic spectrum, $I_{iso}$, is then constructed:

\[ I_{iso} = I_{VV} - 4/3 I_{VH}. \]

The depolarization ratio, $\rho$, of the modes were determined according to eqn (4):

\[ \rho = I_{VH}/I_{VV} = 3\gamma^2(45\alpha^2 + 4\gamma^2). \]

In order to obtain spectra defined as $I(\vec{p})$ which are independent of the excitation wavenumber $\nu_1$, the measured Stokes intensity should be corrected for the scattering factor ($\nu_1 - \vec{p}$)$^3$. When counting methods are used, the measured count rates have to be corrected with the factor ($\nu_1 - \vec{p}$)$^3$. The spectra were further corrected for the Bose–Einstein temperature factor, $B = [1 - \exp(-h\nu/kT)]$ and the frequency factor, $n$, to give the so called reduced or $R(\vec{p})$ spectrum. It is also possible to calculate the isotropic spectrum in $R$-format from the corrected $R_{VV}$ and $R_{VH}$ spectra according to eqn (5):

\[ R(\vec{p})_{iso} = R(\vec{p})_{VV} - 4/3 R(\vec{p})_{VH}. \]

Temperature dependent Raman measurements were carried out in scalable fused quartz cuvettes, 10 × 10 mm, with 3.5 mL volume from Hellma (Müllheim, Germany) using a home-built oven. The oven and the setup have been described in detail in ref. 17.

2.3. Quantitative Raman measurements of the sulfato complex formation

In order to be able to quantify species in solution without using an internal standard, the relative molar scattering factors (RMSF) for those bands must be determined.$^{18}$ The RMSF for $\nu_1$-SO$_4^{2-}$ at 980 cm$^{-1}$ for “free” SO$_4^{2-}$ in (NH$_4$)$_2$SO$_4$ solutions were measured in solutions in which a known amount of NH$_4$ClO$_4$ had been dissolved as an internal standard (ClO$_4^-$ band $\nu_1$ at 931 cm$^{-1}$). From the integrated band intensities, $A_0$, and the concentration of the standard, the relative integrated band

\[ I_{VV} = I(1[YZ]X) = 45\alpha^2 + 4\gamma^2 \]  
\[ I_{VH} = I(1[Y]Z)X = 3\gamma^2. \]

The isotropic spectrum, $I_{iso}$, is then constructed:

\[ I_{iso} = I_{VV} - 4/3 I_{VH}. \]

The depolarization ratio, $\rho$, of the modes were determined according to eqn (4):

\[ \rho = I_{VH}/I_{VV} = 3\gamma^2(45\alpha^2 + 4\gamma^2). \]

The polarization analyser was calibrated with CCl$_4$ before each measuring cycle and adjusted if necessary. The depolarization ratio of the $\nu_1$ mode of CCl$_4$ at 45$^9$ cm$^{-1}$ was determined at 0.0036 ± 0.0005 (15 independent measurements). The depolarization ratios of the depolarized CCl$_4$ bands at 217 cm$^{-1}$ and 315 cm$^{-1}$ have been determined at 0.75 ± 0.02.

In order to obtain spectra defined as $I(\vec{p})$ which are independent of the excitation wavenumber $\nu_1$, the measured Stokes intensity should be corrected for the scattering factor ($\nu_1 - \vec{p}$)$^3$. When counting methods are used, the measured count rates have to be corrected with the factor ($\nu_1 - \vec{p}$)$^3$. The spectra were further corrected for the Bose–Einstein temperature factor, $B = [1 - \exp(-h\nu/kT)]$ and the frequency factor, $n$, to give the so called reduced or $R(\vec{p})$ spectrum. It is also possible to calculate the isotropic spectrum in $R$-format from the corrected $R_{VV}$ and $R_{VH}$ spectra according to eqn (5):

\[ R(\vec{p})_{iso} = R(\vec{p})_{VV} - 4/3 R(\vec{p})_{VH}. \]

In the low wavenumber region the $I(\vec{p})$ and $R_0(\vec{p})$ spectra are significantly different and only the spectra in $R$-format are presented. It should be noted that one of the advantages of using isotropic $R$-spectra is that the baseline is almost flat in the 50–700 cm$^{-1}$ wavenumber region allowing relatively unperturbed observation of the presence of any weak modes.$^{15,16}$

The spectra were fitted to a sum of Lorentzian–Gaussian product functions and the fitting procedure has been described elsewhere in detail.$^{17}$

Temperature dependent Raman measurements were carried out in scalable fused quartz cuvettes, 10 × 10 mm, with 3.5 mL volume from Hellma (Müllheim, Germany) using a home-built oven. The oven and the setup have been described in detail in ref. 17.

2.3. Quantitative Raman measurements of the sulfato complex formation

In order to be able to quantify species in solution without using an internal standard, the relative molar scattering factors (RMSF) for those bands must be determined.$^{18}$ The RMSF for $\nu_1$-SO$_4^{2-}$ at 980 cm$^{-1}$ for “free” SO$_4^{2-}$ in (NH$_4$)$_2$SO$_4$ solutions were measured in solutions in which a known amount of NH$_4$ClO$_4$ had been dissolved as an internal standard (ClO$_4^-$ band $\nu_1$ at 931 cm$^{-1}$). From the integrated band intensities, $A_0$, and the concentration of the standard, the relative integrated band
intensities, \( I_R \), with \( I_R = (A_{\text{HHO}}/A_{\text{O3}})C_{\text{HHO},\text{ClO}_4} \) were calculated. The quantity \( I_R \) is directly proportional to the concentration of the species of interest and thus: \( I_R = JC \). From the slope of the curve, \( I_R = JC \), the so called relative molar scattering coefficient, \( J \) was obtained. For \( r_1 \text{SO}_4^2 \) at 980 cm\(^{-1}\), it follows \( J_{980} = 0.788 \) and for bound sulfate at 991 cm\(^{-1}\), \( J_{991} = 0.760 \).

The equilibrium concentrations of \([\text{SO}_4^2^-]_{\text{free}}\) and \([\text{SO}_4^2^-]_{\text{bound}}\) were obtained from the ratios of the areas of “free” \( \text{SO}_4^2^- \) mode at 980 cm\(^{-1}\) (this mode includes contributions from the fully hydrated sulfate, in the outer-outer-sphere and outer-sphere\(^{34-35}\)) and the bound \( \text{SO}_4^2^- \) mode at 991 cm\(^{-1}\) and the relative molar scattering factors. The sum of the equilibrium concentrations \([\text{SO}_4^2^-]_{\text{free}}\) plus \([\text{SO}_4^2^-]_{\text{bound}}\) is equal to \( C_0 \), the stoichiometric concentration of \( \text{MnSO}_4 \) (in mol kg\(^{-1}\)). The integrated band intensities are \( A_{980} = J_{980}[\text{SO}_4^2^-]_{\text{free}} \) and \( A_{991} = J_{991}[\text{SO}_4^2^-]_{\text{bound}} = J_{991}(C_0 - [\text{SO}_4^2^-]_{\text{free}}) \), where \( J_{980} \) and \( J_{991} \) are the relative molar scattering factors for the bands at \( \sim 980 \) and \( 991 \) cm\(^{-1}\). For the ratio of the integrated intensities, \( A_{980}/A_{991} \) was calculated as follows:

\[
A_{991} = J_{991} \left( C_0 - [\text{SO}_4^2^-]_{\text{free}} \right) / J_{980} [\text{SO}_4^2^-]_{\text{free}}
\]

(6)

and after rearranging for \([\text{SO}_4^2^-]_{\text{free}}\) it follows:

\[
[\text{SO}_4^2^-]_{\text{free}} = \frac{C_0}{J_{980} A_{991} - J_{991}}
\]

(7)

With the equilibrium concentration of \([\text{SO}_4^2^-]_{\text{free}}\) determined and \( C_0 \), the stoichiometric concentration of \( \text{La_2} (\text{SO}_4)_3 \) known, the degree of bound sulfate, \( \alpha \), may be calculated by eqn (8):

\[
\alpha = (C_0 - [\text{SO}_4^2^-]_{\text{free}})/C_0.
\]

(8)

3. Results and discussion

3.1. The unassociated \([\text{La(OH}_2)_3]^{3+}\)(aq)

The \( \text{La}^{3+}(\text{aq}) \) ion is strongly hydrated in aqueous solution due to its high charge to radius ratio. A recent DFT study on a \([\text{Li}_{6.5} \text{H}_2 \text{O}_{3.5}]^{3+}\) cluster imbedded in a polarizable dielectric continuum, taking into account the bulk water molecule in a tricapped trigonal prism (TTP) polyhedral of symmetry \( D_5 \). The oxygen atoms of three water molecules in the equatorial plane are separated from \( \text{La}^{3+} \) by a bond distance of 2.64 Å, while six water molecules at the vertices of the trigonal prism are found at an average \( \text{La-O} \) bond distance at 2.515 Å.\(^{4,5}\) The hydration sphere of \( \text{La}^{3+}(\text{aq}) \) is labile and a water-exchange rate constant \( k_{\text{ex}} \) at 25 °C was given at \( \geq 2 \times 10^8 \text{ s}^{-1} \) (estimated from \( \text{H}_2\text{O} - \text{SO}_4^{2-} \) interchange rates) and a water residence time \( \tau = 5 \text{ ns} \) follows.\(^{19,20}\) Because of the labile coordination sphere for \( \text{La}^{3+} \) there is the possibility of a counterion (anion) coordination replacing water from the coordination polyhedron.\(^{21}\)

Although perchlorate is considered a non-complex forming anion, in \( \text{La(ClO}_4)_3 \) solutions at higher salt concentrations (1.5 mol L\(^{-1}\)), it was shown that perchlorate forms outer sphere-ion pairs, \([\text{La(OH}_2)_3]^{3+}\)ClO\(_4^-\) and at yet higher concentrations perchlorate penetrates into the first hydration sphere of the \( \text{La}^{3+} \). In \( \text{La(ClO}_4)_3(\text{aq}) \) at 2.488 mol L\(^{-1}\) the mole ratio solute to water is 15.7 and this amount of water is barely enough to completely hydrate the \( \text{La}^{3+} \) ion while the remaining 6.7 water molecules hydrate the three ClO\(_4^-\) ions. In such a concentrated solution contact ion pair formation is simply forced on \( \text{La}^{3+} \). Therefore, it is necessary to measure dilute \( \text{La(ClO}_4)_3 \) solutions but this measurement is hampered by the fact that the \( \text{La-O} \) breathing mode is very weak and its Raman scattering coefficient, 0.030, is low.

A vibrational analysis of the \( \text{LaO}_9 \) skeleton modes of the \([\text{La(OH}_2)_3]^{3+}\)(aq) species (\( D_{3h} \) symmetry) has been carried out recently.\(^4\) Twenty four normal modes (n.m.’s) are expected for the \( \text{LaO}_9 \) skeleton modes of the nonahydrate \([\text{La(OH}_2)_3]^{3+}\). The irreducible representation of the vibrational modes is as follows: \( \Gamma_{\text{vib}}(\text{D}_{3h}) = 3a_1(Ra) + a_2(Ra) + 5e(Ra, i.r.) + a_1'(Ra) + 3a_1'(i.r.) + 3e'(Ra) \). Two stretching modes and a bending mode are expected with character \( a_1' \) and these modes are Raman active only. Two stretching modes and three bending modes occur with character \( e' \) and these modes are infrared and Raman active. A stretching mode and two bending modes for character \( a_2' \) are expected and these n.m.’s are infrared active only while three modes (one stretch and two bending modes) with character \( e'' \) are only Raman active. The modes with character \( a_2' \) and \( a_1'' \) are torsional modes and are not active. However, it was evident that only the symmetric \( \text{La-O} \) stretching mode appears in the Raman effect. The remaining \( \text{LaO}_9 \) modes are too weak to be identified in Raman and this has also been observed for other metal ion-oxygen modes in aqueous solution.\(^4\) The La(ClO\(_4\))\(_3\) solution spectra reveal a Raman mode for the \([\text{La(OH}_2)_3]^{3+}\) species, which is very weak, strongly polarized and broad at 343 cm\(^{-1}\). A 0.249 mol L\(^{-1}\) \( \text{La(ClO}_4)_3 \) solution is presented in Fig. 1. In neither \( \text{NaClO}_4(\text{aq}) \) nor \( \text{HClO}_4(\text{aq}) \) was this mode observed and must therefore stem from a symmetrical vibration connected to a \( \text{La-O} \) stretching band.

The perchlorate modes are well characterized so only a brief description is given.\(^4\) The ClO\(_4^-\) ion possesses \( T_d \) symmetry and has nine modes of internal vibrations spanning the representation \( \Gamma_{\text{vib}}(T_d) = 3a_1(Ra) + e(Ra) + 2f_2(Ra, i.r.) \). All n.m. are Raman active, but in i.r. only the \( f_2 \) modes are active. The spectra of La(ClO\(_4\))\(_3\)(aq) show the predicted four Raman-active bands for the tetrahedral ClO\(_4^-\)(aq). The \( v_1(Ra) \) ClO\(_4^-\) band centred at 931.5 cm\(^{-1}\) is totally polarized (\( \rho = 0.005 \)) whereas \( v_2(f_2) \) ClO\(_4^-\) centred at 1105 cm\(^{-1}\) is depolarized as are the deformation modes \( v_5(f_2) \) ClO\(_4^-\) at 631 cm\(^{-1}\) and \( v_2(e) \) ClO\(_4^-\) at 463 cm\(^{-1}\) (Fig. 1).

In addition to the isotropic mode, \( v_1 \) \( \text{LaO}_3 \) at 343 cm\(^{-1}\) (fwhh = 49 ± 2 cm\(^{-1}\)) a very weak, broad mode centered at 170 ± 10 cm\(^{-1}\) can be observed in aqueous \( \text{La(ClO}_4)_3 \) solution (isotropic Raman scattering). The mode can also be seen in pure water at \( \sim 175 \) cm\(^{-1}\) and is moderately intense but slightly polarized. This mode has been assigned to a restricted translational mode of the H-bonded water molecules and is strongly anion and...
Fig. 1 Raman scattering profiles of a 0.249 mol L$^{-1}$ (R$_w$ = 214) La(ClO$_4$)$_3$(aq). Upper panel: $R_{pol}$ and $R_{depol}$ scattering. Note the very weak band at 343 cm$^{-1}$ due to the symmetric breathing mode of [La(OH)$_3$]$^{3+}$. In addition, the deformation modes of ClO$_4^-$ (aq) which dominate the spectrum at 460 cm$^{-1}$ and 628 cm$^{-1}$ are shown. The band at 178 cm$^{-1}$ ($R_{pol}$) is due to the restricted O---H---O bonds of the water H-bond network. Lower panel: Isotropic scattering in $R$-format. Note the very weak band at 343 cm$^{-1}$ due to the symmetric breathing L-O mode. The isotropic mode at 182 cm$^{-1}$ is due to the restricted O---H---O bonds of the water H-bond network.

Fig. 2 Overview Raman profiles of a 0.101 mol L$^{-1}$ Na$_2$SO$_4$ solution. The $I_{VV}$ and $I_{VH}$ scattering orientations (upper panel) are given and in the lower panel the isotropic scattering.

The non-associated SO$_4^{2-}$ (aq) ion possesses $T_d$ symmetry and thus nine modes of internal vibration, having the representation: $I_{vib}(T_d) = a_1(R) + e(R) + 2f_2(R, IR)$. All vibrational modes are Raman active, one mode with character $a_1$ is totally polarized, and three modes with character $e$ and $f_2$ are depolarized but only the $f_2$ modes are IR allowed.

In the IR spectrum only two sulfate bands are active, namely $v_1$($f_2$) and $v_3$($f_2$) located at 618 cm$^{-1}$ and 1104 cm$^{-1}$ respectively but all four modes are Raman active. Detailed Raman spectroscopic characterizations of the SO$_4^{2-}$ (aq) bands are given in ref. 24. The $v_1$($a_1$)-SO$_4^{2-}$ mode is the strongest band in the sulfate spectrum. The band for a 0.101 mol L$^{-1}$ Na$_2$SO$_4$(aq) centred on 980.69 cm$^{-1}$ (fwhh = 6.05 ± 0.05 cm$^{-1}$) is almost totally polarized ($\rho = 0.0035$) whereas the $v_2$($f_2$)-SO$_4^{2-}$ band centred on 1109 cm$^{-1}$ (fwhh = 65.0 cm$^{-1}$) is depolarized. The deformation modes $v_4$($f_2$)-SO$_4^{2-}$ at 614 cm$^{-1}$ (fwhh = 31 cm$^{-1}$) and $v_2$($e$)-SO$_4^{2-}$ at 448 cm$^{-1}$ (fwhh = 35 cm$^{-1}$) are depolarized as well.

At low frequencies, a broad and weak mode at 180 cm$^{-1}$ (fwhh = 168 cm$^{-1}$) was observed in the isotropic R-spectrum. This mode is also observable in pure water at 175 cm$^{-1}$ and has been attributed to H-bonded water molecules. In Na$_2$SO$_4$(aq) it may be assigned to the restricted translational modes of both OH---O and OH---(OSO$_3$)$_2$ hydrogen-bonds thereby the contribution of the OH---(OSO$_3$)$_2$ hydrogen-bonds increases with increasing Na$_2$SO$_4$ concentration. In a concentrated, saturated Na$_2$SO$_4$ solution, 1.617 mol L$^{-1}$, the restricted translational mode, $v$ OH---O was observed at 185 cm$^{-1}$ with a fwhh at 130 cm$^{-1}$ while in dilute solutions the restricted translational mode is determined by the OH---O hydrogen bonds in water and only slightly influenced by OH---(OSO$_3$)$_2$ hydrogen-bonds. The corresponding bending mode of this unit appears at ~60 cm$^{-1}$. Here, however, a brief discussion of the results relevant to the ligated sulfate is presented.
mol L\(^{-1}\) Na\(_2\)SO\(_4\) solution \((R_w = 32.75)\), \(r_{\text{max}}\) for this isotropic band appears at 981.04 cm\(^{-1}\) with a fwhh = 6.60 cm\(^{-1}\), for a 0.101 mol L\(^{-1}\) solution \((R_w = 552.2)\) \(r_{\text{max}}\) appears at 980.69 cm\(^{-1}\) with a fwhh = 6.05 cm\(^{-1}\). For an infinitely dilute solution (extrapolation to zero concentration) the \(v_1\text{-SO}_4^{2-}\) band appears at 980.45 cm\(^{-1}\) and a fwhh = (5.55 ± 0.05) cm\(^{-1}\). For present purposes, it is relevant that the symmetric profile of the \(v_1\text{-SO}_4^{2-}\) mode was independent of the salt concentration over the entire range studied \((≥1.617\text{ mol L}^{-1}\)). The \(v_1\text{-SO}_4^{2-}\) band is the strongest band in the \(\text{SO}_4^{2-}\text{-aq}\) Raman spectrum and the intensity ratio of \(v_1\text{-SO}_4^{2-}\text{-band area to } v_3\text{-SO}_4^{2-}\text{band area is 9:1.}

The band contour of the antisymmetric S-O stretching mode, \(v_3\text{-SO}_4^{2-}\) is also symmetrical in both polarization arrangements but band parameters vary slightly with concentration. For example, at 23 °C for a 1.617 mol L\(^{-1}\) Na\(_2\)SO\(_4\) solution, \(r_{\text{max}}\) is found at \((1112 ± 2)\) cm\(^{-1}\) and shifted to slightly lower wavenumbers as the concentration was decreased, reaching \((1106 ± 2)\) cm\(^{-1}\) at infinite dilution. The fwhh decreased from \((76 ± 2)\) cm\(^{-1}\) for a 1.617 mol L\(^{-1}\) salt solution to \((67 ± 2)\) cm\(^{-1}\) for a 0.100 mol L\(^{-1}\) solution reaching \((64 ± 2)\) cm\(^{-1}\) at infinite dilution. It is important to state that the symmetric profile of the \(v_3\text{-SO}_4^{2-}\) band which is completely depolarized is independent of the Na\(_2\)SO\(_4\) concentration over the entire range studied (Fig. 2).

### 3.3. Raman spectra of La\(_2\)(SO\(_4\))\(_3\text{(aq)}\)

The Raman spectra of La\(_2\)(SO\(_4\))\(_3\) in aqueous solution show additional features to those in the unassociated sulfate spectra and the \([\text{La(OH}_3\text{)}_3]^{3+}\text{aq})\) mode which have been described above. La\(_2\)(SO\(_4\))\(_3\) is only sparingly soluble in water and the Raman signals are therefore of low intensity and the spectra are dominated by the solvent, water. Nevertheless these additional spectroscopic features could be observed and are now discussed in detail.

An overview Raman spectrum of the 0.0376 mol L\(^{-1}\) La\(_2\)(SO\(_4\))\(_3\) solution is presented in Fig. 4. Because of the low solute concentration, the sulfate bands appear weak and the scattering spectrum is dominated by the bands of the solute, water. The \(v_1\text{-SO}_4^{2-}\) stretching profile shows two band components at 981 cm\(^{-1}\) and at 991 cm\(^{-1}\). The weak antisymmetric stretching mode, \(v_3\text{-SO}_4^{2-}\) at 1112 cm\(^{-1}\) appears broader compared to a comparable Na\(_2\)SO\(_4\) solution. Furthermore, in the terahertz frequency range, the La-O breathing mode, normally at 343 cm\(^{-1}\), appears in the difference spectrum of the 0.0376 mol L\(^{-1}\) La\(_2\)(SO\(_4\))\(_3\) solution as a broad feature at ∼328 cm\(^{-1}\) with two separate component bands, one at 343 cm\(^{-1}\) assigned to the La-O breathing mode of \([\text{La(OH}_2\text{)}_9\text{]}^{3+}\text{aq})\) and one at 312 cm\(^{-1}\) assigned to hydrated La\(^{3+}\) where sulfate occurs in the first hydration shell. \([\text{La(OH}_2\text{)}_3\text{OSO}_4\text{]}\) (aq) (Fig. 5). With further dilution of La\(_2\)(SO\(_4\))\(_3\) the very small scattering coefficient of this La-O breathing mode prevents further observation of this band.

The split of the \(v_1\text{-SO}_4^{2-}\) stretching band into a band at 981 cm\(^{-1}\) and a pronounced shoulder at 991 cm\(^{-1}\) becomes immediately obvious in Fig. 6B. In Na\(_2\)SO\(_4\) (aq) the strongly polarized mode at 991 cm\(^{-1}\) is absent while in a variety of divalent and trivalent metal sulfate solutions sulfato-complex species could be observed.\(\text{A}^{1\text{11,12,24}}\) In Fig. 7, a concentration plot of \(v_1\text{-SO}_4^{2-}\) band profiles are given, showing the concentration dependence of four representative Raman...
is the band of a sulfato-complex species. A similar observation was made in a similar system, MgSO4(aq), for which a dynamic exchange model was proposed to explain the occurrence of the band at 995 cm^{-1}. (The 995 cm^{-1} band in MgSO4(aq), however, is the band of a sulfato-complex species.)

The deformation bands of sulfate, ν_2 SO_4^{2-} at 448 cm^{-1} and the band ν_4 at 614 cm^{-1} are broadened compared to the ones in Na_2SO_4(aq) of comparable sulfate concentrations [Fig. 2, 3 and 6A]. These two deformation bands are depolarized in the Raman scattering as shown in the lower panel of Fig. 6A. The anti-symmetric stretch ν_3 SO_4^{2-} is much broader than Na_2SO_4(aq) of comparable sulfate concentration and shows a band contour with peak positions at 1088 cm^{-1}, 1127 cm^{-1} and 1158 cm^{-1} and in the broad band at 1109 cm^{-1} for “free” sulfate (compare band contour of Na_2SO_4(aq) spectra). The measured anisotropic band profile of ν_3 SO_4^{2-} is shown in Fig. S1† together with the sum curve of the band fit. All these spectroscopic features of the sulfate in La_2(SO_4)_3 solutions lead to the conclusion that sulfate must have penetrated the first hydration shell of La^{3+}(aq) forming a well-defined La^{3+}-sulfato complex. In the terahertz frequency range of La_2(SO_4)_3(aq) of a 0.376 mol L^{-1} solution, as mentioned above, the La-O bond of the LaO_6 skeleton appears as a broad feature at ~328 cm^{-1} while the fully hydrated, [La(OH_2)_3]^+ occurs at 343 cm^{-1}. The downshift of the La^{3+}-sulfato complex, [La(OH_2)_3(OSO_4)]^3- compared with the fully hydrated cation was detected in other trivalent-metal sulfate solutions. It should be pointed out that the scattering intensity of the broad La-O features is very small and the solutions are quite dilute. Only in Al_2(SO_4)_3, Ga_2(SO_4)_3, and In_2(SO_4)_3 solutions which are considerably more soluble than La_2(SO_4)_3 and therefore much easier to detect, is such a split into the aqua mode of the fully hydrated species observable without the sulfate and partially hydrated metal–sulfato complex species.\(^{8,11,12}\)

An overview Raman spectrum of a 0.035 mol L^{-1} La_2(SO_4)_3 solution in heavy water is presented in Fig. S2 (ESI†). The

**Fig. 5** Band fit result on a difference Raman scattering profile (polarized scattering) of a 0.0376 mol L^{-1} La_2(SO_4)_3 solution from which the water background was subtracted. In addition to the difference Raman spectrum of the broad band feature, the sum curve of the fit and the two band components at 312 cm^{-1} and 343 cm^{-1} are shown.

**Fig. 6** (A) Raman scattering profiles (polarized, depolarized and isotropic) of a 0.0376 mol L^{-1} La_2(SO_4)_3 solution in the low wavenumber region from 100–900 cm^{-1}. Shown are the restricted translation band O⋯H⋯O at 181 cm^{-1} and the very broad and dominating bands at ca. 455 and 720 cm^{-1} due to the librational bands of H_2O. The two weak deformation modes of SO_4^{2-} at 448 and 614 cm^{-1} are “sitting” on the broad librational band structure. (B) Raman scattering profiles of a 0.0376 mol L^{-1} La_2(SO_4)_3 solution. Upper panel: Wavenumber range from 850–1250 cm^{-1} showing the ν_1 SO_4^{2-} and ν_3 SO_4^{2-} stretching region of sulfate. Lower panel: Enlarged wavenumber region from 920–1040 cm^{-1} depicting the S–O stretching band region. Note the split of the S–O stretching band into a band at 981.5 cm^{-1} of “free” SO_4^{2-} and coordinated SO_4^{2-} at 991.5 cm^{-1} appearing as a well pronounced shoulder. Underneath is the depolarization degree as a function of wavenumbers.
La\(^{3+}\)(aq) + SO\(_4^{2-}\)(aq) \xrightarrow{K_1} La\(^{3+}\)(OH\(_2\))SO\(_4^{2-}\) \xrightarrow{K_2} \text{fully hydrated ions} \xrightarrow{K_3} \text{outer-outerver-sphere complex} \xrightarrow{K_4} \text{inner-sphere complex} \quad (9)

where \(K_i\) (i = 1 to 3) are the 'stepwise' constants for the corresponding equilibria. The first equilibrium step is the diffusion controlled step and defined as:

\[
K_1 = \frac{[\text{La}^{3+}(\text{OH}_2)\text{SO}_4^{2-}]}{[\text{La}^{3+}(\text{aq})][\text{SO}_4^{2-}(\text{aq})]} \quad (10)
\]

The second step, the intermediate step, resulting in outer-sphere complex is defined as:

\[
K_2 = \frac{[\text{La}^{3+}(\text{OH}_2\text{SO}_4^{2-})]}{[\text{La}^{3+}(\text{OH}_2)\text{SO}_4^{2-}]} \quad (11)
\]

and the third step, the rate determining step, is defined as:

\[
K_3 = \frac{[\text{La}^{3+}\text{OSO}_3^{2-}]}{[\text{La}^{3+}(\text{OH}_2)\text{SO}_4^{2-}]} \quad (12)
\]

The rate constants of the forward and backward reaction, the rate determining step via \(\text{La}^{3+}(\text{OH}_2)\text{SO}_4^{2-} \rightarrow \text{La}^{3+}\text{OSO}_3^{2-} + \text{H}_2\text{O}\), may be formulated via \(K_i = k_i/k_b\). The rate constants for forward (\(k_i\)) and backward (\(k_b\)) reactions were published from earlier ultrasound absorption measurements.\(^{19,20,24,35}\)

The overall association constant, \(K_{\alpha}\), as measured by traditional techniques such as potentiometry or conductivity, corresponds to the equilibrium:

\[
\text{La}^{3+}(\text{aq}) + \text{SO}_4^{2-}(\text{aq}) \leftrightarrow \text{LaSO}_4^{\alpha}(\text{aq}) \quad (13)
\]

where \(\text{LaSO}_4^{\alpha}(\text{aq})\) refers to all forms of associated \{\(\text{La}^{3+}, \text{SO}_4^{2-}\)\} species of 1 : 1 stoichiometry in aqueous solution (thermodynamics makes no distinction between dissolved species of identical stoichiometry but with differing levels of hydration\(^{34,35}\). The \(K_{\alpha}\) value, the overall association constant for the three step mechanism is related to the individual \(K_i\) values via eqn (14):

\[
K_{\alpha} = K_1 + K_1K_2 + K_1K_2K_3 \quad (14)
\]

Three \(K_i\) values were obtained from ultrasound absorption (UA) experiments\(^{19,20}\) namely \(K_1 = 435, K_2 = 1.96\) and \(K_3 = 3.7\). The reported \(K_{\alpha}\) value, 4200, derived from UA is too large compared with the recommended \(K_{\alpha}\) value at 3620 at 25 °C.\(^{19,20,24,35}\)

The \(\nu_1\)-SO\(_4^{2-}\) band can be fitted with three band components, a component of the 'free' SO\(_4^{2-}\)(aq) band at \(-980\) cm\(^{-1}\), a component at 983 cm\(^{-1}\) representing the SO\(_4^{2-}\) in the outer-sphere-complex and the mode of the sulfato-complex at 991 cm\(^{-1}\) (Fig. 6B). The sulfato-complex band is quite distinct, while the band of the outer sphere complex is severely overlapped by the SO\(_4^{2-}\)(aq) band at 980 cm\(^{-1}\). The SO\(_4^{2-}\) band of the outer-outerver-sphere complex is not distinguishable from the band of the free sulfate.

The degree of the sulfato-complex formation \(\alpha\), represents the spectrosopically-determined fraction of sulfate present as...
sulfate complex according to eqn (8). Fig. 8 shows the present quantitative Raman results as a function of the stoichiometric $\text{La}_2(\text{SO}_4)_3$ concentration. The proportion of the inner-sphere complex formed appears almost insensitive to the concentration > 0.003 mol L$^{-1}$ but below this concentration vanishes more severely. This paradox can be resolved if it is assumed that the inner-sphere complex, $[\text{LaSO}_4]^-$, is in equilibrium with the outer-sphere complex, $[\text{La}(_2\text{H}_2\text{O})\text{SO}_4]^-$ and not with the "free" sulfate. The Raman spectroscopically determined $K_s$ value was determined according to eqn (12). In Table S1 (ESI†) the data of the analytical curve fitting on the $r_1\text{-SO}_4^{2-}$ band profile of the two band components at 981 cm$^{-1}$ and 991.1 cm$^{-1}$ are given such as integrated band intensities, $A_{981}$ and $A_{991}$, as well as the degree of sulfate-complex formation of the equilibrium between the outer-sphere complex and the inner-sphere-sulfato complex. From these data a $K_s$ value was determined at 0.90 ± 0.1 at 23 °C and it appears that the Raman derived $K_s$ value is comparable to the UA-values considering the uncertainty of the data from the UA measurements.$^{19,20,34,35}

**Temperature dependent measurements.** A 0.0094 mol L$^{-1}$ $\text{La}_2(\text{SO}_4)_3$ solution was measured from 23 to 98 °C and the temperature dependent isotropic scattering profiles are given in Fig. 9. Generally, the peak position of the $r_1\text{-SO}_4^{2-}$ band complex shifts to slightly lower wavenumbers with temperature increase. The band of "free" sulfate at 23 °C peaks at 981.0 cm$^{-1}$ and shifts to 976.5 cm$^{-1}$ at 98 °C. A similar peak shift was observed for the band of the coordinated sulfate which peaked at 991 cm$^{-1}$ at 23 °C and shifts to 987 cm$^{-1}$ at 98 °C. Furthermore, the band complex (and the band components) broadens with temperature. In addition to these two already resolved band components a third band component assigned to sulfate of the outer-sphere ion pair, $\text{La}^3^+(_2\text{H}_2\text{O})\text{SO}_4^{2-}$ was detected at 983 cm$^{-1}$ at 23 °C which shifted to 978.6 cm$^{-1}$ at 98 °C. The results of a three component band fit on the $r_1\text{-SO}_4^{2-}$ band complex are given in Table S2 (ESI†). The most striking fact, however, is the rise of the band component of the coordinated sulfate band, the so called bound sulfate, and the degree of sulfato-complex formation rises from 0.25 at 23 °C to 0.42 at 98 °C.

The increase of the $\text{La}^3^+\text{--sulfato}$ complex with enhancing temperature shows that the rate determining third step of reaction (10) is an endothermic process by which heat is absorbed, making the enthalpy change positive. The change of the equilibrium constant as a function of temperature follows the equation:

$$
\ln(K_s) = -\frac{\Delta H^0}{RT} + \frac{\Delta S^0}{R}.
$$

(15)

Plotting $\ln K_s$ as a function of $1/T$ and assuming that the change of the heat capacity in this small temperature range is zero leads to the enthalpy and the entropy of the last step of the sulato-complex formation, the outer-sphere, inner-sphere-sulfato complex formation according to $\text{La}^3^+(_2\text{H}_2\text{O})\text{SO}_4^{2-} \rightarrow \text{La}^3\text{OSO}_4^{2-}$. The following quantitative results were derived from the temperature-dependence of $\ln(K_s)$ as a function of the reciprocal temperature (in Kelvin): $\Delta H^0 = 18.6$ kJ mol$^{-1}$ and $\Delta S^0 = 62.1$ J mol$^{-1}$ K$^{-1}$. The enthalpy for the rate determining step of eqn (9) compares favorably with the extrapolated value, 15 kJ mol$^{-1}$, for $\Delta H^0$ taken from ref. 39.

Finally, it should be mentioned that Malatesta and co-workers$^{40}$ showed, by comparing activity coefficient data on
La$_2$(SO$_4$)$_3$(aq) and La(ClO$_4$)$_3$(aq), that in the sulfate system of La$^{3+}$ “there is evidence of short-range interactions that add to long-range interactions for lanthanum and bivalent metal sulfates, as if sulfate ions were displacing water from the hydration shells of the cations”. This is exactly what the Raman spectroscopic data show.

4. Conclusions

Raman spectroscopic measurements have been made of aqueous solutions of La(ClO$_4$)$_3$, La$_2$(SO$_4$)$_3$, and Na$_2$SO$_4$ in water and heavy water, in the terahertz frequency region (40–1400 cm$^{-1}$) and down to low concentrations (0.000263 mol L$^{-1}$). Temperature dependent measurements have been carried out on a 0.0098 mol L$^{-1}$ La$_2$(SO$_4$)$_3$ solution from 23–98 °C. In solutions of La(ClO$_4$)$_3$ with water and heavy water, the [La(OH$_2$)]$^{3+}$ and [La(OD$_2$)]$^{3+}$ have been characterized and a weak, strongly polarized band observed at 343 cm$^{-1}$ and 326 cm$^{-1}$ respectively assigned to the $v_1$ LaOH mode, the breathing mode of the clusters. The Raman spectroscopic data suggest that the [La(OH$_2$)]$^{3+}$ ion is thermodynamically stable in dilute perchlorate. No inner-sphere complexes in these dilute solutions could be detected spectroscopically.

In La$_2$(SO$_4$)$_3$(aq), in addition to the $v_1$SO$_4^{2-}$ mode at 980 cm$^{-1}$, a pronounced band component at 991 cm$^{-1}$ has been assigned to an inner-sphere complex (ISC). The sulfate is most likely bound as a monodentate ligand ([LaOSO$_3$]$^+$). Conformation of this assignment is provided by the component at 312 cm$^{-1}$ of the [La(OH$_2$)$_2$SO$_4$]$^+$ unit in addition to the band at 343 cm$^{-1}$ for the fully hydrated cluster, [La(OH$_2$)$_2$]$.^+$ A similar $v_1$SO$_4^{2-}$ band contour has been observed in La$_2$(SO$_4$)$_3$ solutions in heavy water. After subtraction of the component of the ISC at 991 cm$^{-1}$, the $v_1$SO$_4^{2-}$ band in La$_2$(SO$_4$)$_3$(aq) showed systematic differences from that in (NH$_4$)$_2$SO$_4$(aq) and dilute Na$_2$SO$_4$(aq).

This is consistent with a $v_1$SO$_4^{2-}$ band at 983.3 cm$^{-1}$ that can be assigned to the existence of an outer-sphere complex ion (OSCs). The band profile of the weaker antisymmetric S–O stretching mode, $v_2$SO$_4^{2-}$ shows asymmetry and has been fitted with four band components including the component of the “free” $v_2$SO$_4^{2-}$ band reinforcing the existence of the ligated sulfate. In aqueous La$_2$(SO$_4$)$_3$ solutions thermodynamically stable ISC have been detected down to very low concentrations at 0.00026 mol L$^{-1}$ and in addition an OSC, [La(OH$_2$)SO$_4$]$^+$ and the free non-ligated sulfate. The observed change of the equilibrium concentration of the ISC, [LaOSO$_4$]$^+$ with dilution reflects the stepwise sulfato-complex formation. A $K_	ext{rev}$ value has been determined at –0.9 of the equilibrium between OSC and ISC.

Temperature dependent measurements (23–98 °C) on a 0.0098 mol L$^{-1}$ La$_2$(SO$_4$)$_3$ solution has shown that the concentration of the La$^{3+}$ sulfato-complex rises with increasing temperature while at the same time the concentration of the “free” sulfate diminished. The sulfato-complex formation is an endothermic process absorbing heat with increasing temperature. The following thermodynamic parameters for the rate determining equilibrium, [La(OH$_2$)SO$_4$]$^+$ $\leftrightarrow$ [LaOSO$_4$]$^+$ + H$_2$O, has been determined: $\Delta H^0 = 18.6$ kJ mol$^{-1}$ and $\Delta S^0 = 62.1$ J mol$^{-1}$ K$^{-1}$.
