Abstract. The growth of environmental pollution especially in big cities dictates the need to search for the reasons of this trend, most of which refer to the economic sphere. The aim of this work is not only to describe the state of environment in Russian cities with the population of 100 thousand inhabitants and more, but also to reveal the main economic factors that influence on the intensity of their environmental pollution. The ecological and economic analysis of Russian cities, fulfilled in this work, helped to identify the most unfavourable of them in terms of the level of environmental impact. The low quality of environment in these cities is largely due to natural and climatic conditions (bad conditions for contaminants dispersion) and specifics of their economic development: functioning of large industrial enterprises of ferrous and non-ferrous metallurgy, petrochemistry, construction industry. The conclusion is that to improve the environmental quality in these cities comprehensive social, environmental and economic solutions are required.

1. Introduction

It is well-known that at the planetary scale the most important global economic problem of the modern society is the ecological one. Environmental safety is influenced by the number of factors, the most significant among which is the economic growth as the result of modern achievements in science and technology. On the other hand, in the system "society - production - nature" a key place is occupied by modern scientific and technological achievements and they should be regarded as the effective means of scientific and technical development of natural environment.

The organizational and economic mechanism of nature management should be directed not only to the use of science and technology achievements in the sphere of material production, but also to the ecologization of productive processes themselves. The ecologization of material production processes implies their compliance with the principle of their "inscribing" into natural processes. In the last quarter of the century this principle became especially actual not only for agriculture, forestry, livestock husbandry, but also for other sectors of economy, including urban economy (Khaikin M.M., Zhukova P.S., 2015).

The latest achievements of scientific and technological progress are realized mainly in urban areas, chiefly in large industrial centre. However, these achievements are often detrimental to quality of life and they have negative consequences. Therefore, the environmental conditions in many cities are evidently unfavourable (Bityukova V.R., 2012).
Taking into account that at the present time approximately 50% of the world’s population lives in urban areas and the forecast value of this indicator will increase to 60% by 2030 and in industrialized countries will exceed 80% (United Nations, 2016), it is obvious that urban areas become the main ones in solving environmental problems.

Thus, within the framework of spatial ecological and economic analysis city is the main object of research. Since the second half of the 19th century urban population growth was so intense in the world and the spheres of material and non-material production developed so rapidly that the state of the environment of a number of cities no longer satisfied the needs of a city dweller as a biocultural creature. The beginning of the processes of active urbanization in our country dates back to the last quarter of the 19th century, which especially intensified after the revolutions of 1917.

Megalopolises qualitatively transform almost all elements of nature: climate, atmosphere, soil, flora, fauna, relief, soils, groundwater and water. 80% of all air emissions and 75% of the total pollution are concentrated in cities. The harmful impact of cities on the state of the environment extends over a distance of about 70–100 km from their borders.

The concept of "pollution" has significantly expanded. Now it includes any biological species, chemical compound, anthropogenic and natural physical agent, which, entering the ecosystem, begins to influence the change of its parameters (Satterthwaite D., Dodman D., 2013).

In Table 1 the most significant ecological problems of cities, which especially exacerbate in connection with the active processes of formation and growth of urban agglomerations, are considered:

| No. | Problem | Directions of Impact |
|-----|---------|----------------------|
| 1   | High loads on lithosphere | Changes in the relief, in the structure of catchment basins, in the properties of lithosphere, formation of caverns as results of construction works; Destruction of natural landscapes in cities and their suburbs as a result of high attendance of recreational areas; the alienation of land for landfills, residential development, motorways; lack of recreational areas; plant diseases as a consequence of changes in the composition of soils, atmosphere and hydrosphere pollution; the formation of "urban" species composition of vegetation |
| 2   | High loads on landscape | Significant changes in the water balance; active exploitation of water resources and changes in the hydrological and hydrogeological situation as consequences; influence of economic activities on the state of sources of drinking water; interaction of surface and ground waters |
| 3   | Problems related to water supply | Acid precipitation; excessive dust content in the atmosphere, "heat islands", etc. |
| 4   | Problems associated with air pollution | Accumulation of solid wastes in urban areas, institutional contradictions accompanying the process of their utilization |
| 5   | Problems of solid waste management | Light pollution, vibration, noise, electromagnetic radiation that have negative impact on the population of a city and its suburbs |
| 6   | Light pollution, vibration, noise, electromagnetic radiation | Light pollution, vibration, noise, electromagnetic radiation that have negative impact on the population of a city and its suburbs |
| 7   | Problems associated with the functioning of city's engineering and transport infrastructure (power supply, sewerage, transport, water, heat, gas, etc.) | Negative impact of engineering and transport infrastructure of a city and its suburbs on the state of urban environment |

2. Literature Review

In this study our attention is concentrated on Russian cities. The ecological problems of Russian cities are very acute. There are various approaches to assessing the quality of urban environment. For example, an ecological rating of Russian cities is drawn up annually by the specialists of the Ministry of Natural Resources and Ecology of the Russian Federation (The Ministry of Natural Resources..., 2016). The rating methodology was developed by the company EY (Ernst & Young) under the order of the Ministry of Natural Resources of Russia, taking into account the recommendations of the Organisation for Economic Co-operation and Development (OECD) and world analogues. This methodology provides for an assessment on basis of 26 indicators, which are grouped according to the following sections: air quality (4 indicators), water consumption and its quality (4 indicators), use of territories (2 indicators), waste management (3 indicators), transport (4 indicators), energy consumption (4 indicators) and environmental impact management (5 indicators). In order to obtain the initial data official requests are sent to all regions of the Russian Federation.

94 cities took part in the last rating of 2015 (as well as in the rating of 2014). Besides the capitals of all regions of Russia and federal cities, 9 other cities participated in the rating: Vyborg, Glazov, Evpatoria, Yelets, Mozhga, Nefteyugansk, Ramenskoye, Sarapul, Surgut. At the same time, 39 cities could not collect enough data for one or several categories and they did not enter the general rating.

In the rating of 2015 leading positions were occupied by Gorno-Altaisk, Moscow, Vologda, Magas and Kursk. Simultaneously Simferopol was the first in air quality, Syktyvkar - in the level of waste management, and Kyzyl - in water quality. Lipetsk, Yuzhno-Sakhalinsk, Salekhard, Vladivostok and Tyumen were in the end of the general rating.

Despite the fact that the ecological rating of Russian cities (described above) is considered to be the most comprehensive, objective and compiled annually (from 2013), its methodology implies the collection of hard-to-access information (for example, the indicator "the share of more ecological transport" from the section "transport"), which is not always reflected in official statistical publications. Moreover, the lack of actual data on indicators reduces the position of a city in the rating, which significantly distorts the results of the assessment.

The rating of sustainable development of Russian cities, which is compiled annually (since 2012) by the rating agency "SGM" (The "SGM" Agency, 2016), is another example of an integrated assessment of environmental quality of cities in Russia.

The methodological basis of the rating is founded on the concept of a triune outcome, which takes into account both economic performance of activities, and social, environmental impact of economic entities or a city/ a region. All three components are included in the final index of sustainable development of a city on the basis of the principle of equivalence.

The assessment of sustainable urban development is based on the analysis of 31 statistical indicators, describing a city by four main categories: social infrastructure (9 indicators), urban infrastructure (7 indicators), economic development (9 indicators), ecology (3 indicators). The three remaining indicators characterize demographic situation in a city. The converted private indicators are included in the final index of a category according to their weight, determined expertly. Only those indicators are used in the assessment that are available for the largest number of cities (at least 95% of the total number). It is worth mentioning that the division of indicators into categories and their number differ depending on the year of rating, which makes it difficult to analyze the dynamics of sustainable development of Russian cities.

Open statistical data on municipalities, the websites of regional divisions of Rosstat and the chargeable statistical portal "Multistat" are the main sources of information for drawing up the rating.

The rating embraces the cities of the Russian Federation with a population of 100 thousand people and more (in 2015 179 Russia's cities met this criterion).

In 2015 the absolute leaders of the sustainable development rating were Tyumen, Surgut and Moscow. The top ten leaders also included Krasnodar, Perm, St. Petersburg, Ekaterinburg, Kazan, Nizhnevartovsk and Neftegansk. The cities-outsiders of the rating were Kamysn, Novocherkassk, Taganrog, Grozny, Murom, Biysk, Miass, Nizhny Tagil, Artem, Belovo.
This rating mainly assesses the level of socio-economic development of cities rather than their sustainability. The ecological component is represented by only three indicators, one of which describes the degree of air pollution (specific emissions of pollutants per 1 sq. km of urban area), the other - the level of water consumption (water consumption per unit of industrial output), the third - the density of urban population. The use of expert assessments when calculating summary indices by categories imparts subjective character to the rating.

3. Methodology
In this study our attention is concentrated on Russian cities with the population of 100 thousand inhabitants and more. In 2015 74% of Russia's population lived in cities; 29% of the urban population - in big cities with a population of 1 million people and more (United Nations, 2016).

The analysis of open, officially published statistics of the Federal State Statistics Service for Russian cities with the population of 100 thousand people and more over a period of 2004 - 2014 (Federal Service of State Statistics (Rosstat), 2005, 2006, 2007, 2009, 2011, 2013, 2015) allowed us to identify cities with unfavourable ecological situation and to determine the trends of pollution of atmospheric air, surface water bodies and land resources. It is worth noting that, unlike regional statistics, municipal one has a very narrow set of indicators and different time series.

In 2013 the Federal State Statistics Service (Rosstat) published the bulletin "Key Environmental Indicators", where, among other things, the data on emissions of air pollutants from stationary sources and road transport were presented for 181 Russian cities for 2012.

In the bulletin of 2015 the data for 2014 were published on the Rosstat website, but these data were focused on regions in general, and not on certain cities. In the survey of 2015 the list of cities is much smaller (37 cities) than in the bulletin of 2013 and the survey of 2015 does not have data on automobile emissions. Therefore, in our study of the most environmentally polluted cities in Russia the data from the bulletin of 2013 (rather than from the one of 2015) were used.

It is also worth mentioning that the distribution of places in the rating by total volume of emissions does not always reflect the real difference in environmental pollution of cities. For example, by total emissions Moscow is in the second place, and Krasnoyarsk is in the 11th place. But in Krasnoyarsk sulfur dioxide prevails in emissions of pollutants (more than 80%), which is 2 times more toxic than nitrogen dioxide, whose content is about 50% in pollutant emissions in Moscow.

4. Results
Figure 1 shows the emission of pollutants into atmosphere (per square kilometer of urban area) in twenty cities of Russia with the highest values of this indicator as of 2012.

In 2012 the leader in the emissions of pollutants from all sources was Norilsk. The basic mass of pollution came from stationary sources, mainly from the world's largest mining and metallurgical plant (Polar Division of Public Joint Stock Company "Mining and Metallurgical Company "Norilsk Nickel"). Cherepovets and Angarsk are also among the top three leaders in this indicator. In other cities the values of this indicator did not exceed the value of 1000 tons per square kilometre of urban area. In 2012 in Moscow the contribution of road transport to air pollution was 93%, in Yaroslavl - 48%, in Ryazan - 38%, in Krasnoyarsk and Chelyabinsk - 37%, in Tula - 33%, in Omsk - 28%. In the other cities, shown in Fig. 1, the main contribution to air pollution was made by stationary sources (enterprises, organizations).

The dynamics of pollutant emissions into atmosphere from stationary sources in twenty cities of the Russian Federation under consideration for the period from 2004 to 2012 testifies to the lack of a common trend for all cities (see Figure 2).

In Angarsk, Novocherkassk and Omsk there is a tendency to the increase in emissions of pollutants into atmosphere from stationary sources (per square kilometre of urban area), in Cherepovets, Sterlitamak, Tula, Achinsk, Severodvinsk, Chelyabinsk, Volzhsky, Salavat and Ryazan - a tendency to the decrease, and in Norilsk, Lipetsk, Moscow, Novokuznetsk, Magnitogorsk, Krasnoyarsk, Nizhny Tagil and Yaroslavl - stabilization at approximately the same level.
Figure 1. Emission of Pollutants into Atmosphere in Twenty Russian Cities with the Highest Values of This Indicator (as of 2012). Source: compiled by the authors.

Figure 2. Dynamics of Pollutant Emissions into Atmosphere from Stationary Sources in Twenty Cities of the Russian Federation - Leaders in Total Pollutant Emissions in 2012. Source: compiled by the authors.

Figure 3 presents the dynamics of pollutants' emissions from road transport in twenty cities of the Russian Federation - leaders in total emissions into atmosphere in 2012, calculated per square kilometre of urban area. This dynamics was formed, using available statistics for three years: 2010, 2012 and 2014. As above no common tendency for the cities under consideration was observed. The clear tendency of growth of pollutants' emissions into atmosphere from road transport was traced in Moscow, Sterlitamak, Chelyabinsk and Salavat, and the reduction of emissions was in Norilsk, Novokuznetsk, Volzhsky and Yaroslavl.

Nine of the considered cities - leaders in total emissions into atmosphere in 2012, calculated per square kilometre of urban area, (Norilsk, Novocherkassk, Moscow, Sterlitamak, Magnitogorsk, Krasnoyarsk, Achinsk, Nizhny Tagil and Chelyabinsk) were included in the Priority List of cities with...
very high levels of atmospheric air pollution. The Priority List was drawn up by specialists of Roshydromet based on the comprehensive analysis of observations in 2012 (Roshydromet, 2013). It includes 28 cities with different population size (including less than 100 thousand people), in which Roshydromet conducts regular observations of atmospheric condition. 20 out of 28 cities are located in the Asian part of Russia, which is characterized by particularly unfavourable climatic conditions for dispersion of impurities.

![Figure 3. Dynamics of Pollutant Emissions into Atmosphere from Motor Transport in Twenty Russian Cities - Leaders in Total Pollutant Emissions in 2012. Source: compiled by the authors.](image)

Further, on the basis of available data for 2008 twenty cities of the Russian Federation with population of 100 thousand people and more - the leaders in the volume of polluted sewage, discharged into surface water bodies, (per capita) were sorted out (see Figure 4). This list of cities differs from the previous one. However, there are cities that are included in both lists. These are Norilsk, Angarsk, Novokuznetsk, Magnitogorsk, Achinsk and Nizhnii Tagil.

Data on the volume of wastewater, discharged into surface water bodies, for Russian cities are given for 2008, since no information for later periods has been published (Federal Service of State Statistics (Rosstat), 2009, 2011, 2013).

In 2008 Angarsk, Bratsk and Magnitogorsk were among the top three leaders in discharging contaminated sewage into surface water bodies. Despite the fact that Angarsk headed this list, the volume of discharged contaminated sewage was 45% of total discharge of sewage. In Bratsk, Syktyvkar, Norilsk, Berezni, Nevinnomyssk and Sterlitamak discharged sewage was also partially cleaned at treatment facilities. In other cities under consideration all wastewater was discharged into surface water bodies without treatment, causing environmental damage.

The dynamic analysis of per capita polluted sewage, discharged into surface water bodies, in twenty cities with the largest values of this indicator for 2008 also shows the absence of a common trend for all cities (see Figure 5). In Angarsk there was a smooth tendency of growth of the this indicator in the four considered years; in Bratsk, Syktyvkar and Berezni there was a clear tendency of its reduction. An explosive increase in the volume of per capita polluted sewage by 87%, 232% and 71%, respectively, took place in Magnitogorsk, Achinsk and Pervouralsk in 2008. In Novomoskovsk there was a sharp decrease in the volume of discharged contaminated sewage by 37% compared to 2006 (see Figure 5).

Thousands, millions cubic meters of solid domestic wastes are generated in cities annually. They can be transported to landfills after or without industrial reprocessing. Waste disposal without recycling causes the greatest damage to environment than waste burial of industrial reprocessing leavings. Table 2 shows twenty Russian cities with the largest per capita volume of solid domestic wastes, buried without their industrial reprocessing, as of 2012.
Table 2. Russian Cities with the Largest Volumes of Solid Domestic Wastes Transported to Landfills without Industrial Reprocessing in 2012.

| No. | City                                      | Removed Solid Domestic Wastes per Year, thousand cubic meters | Solid Domestic Wastes, Buried without Industrial Reprocessing Thousand Cubic Meters | Wastes, Buried per Capita |
|-----|-------------------------------------------|-------------------------------------------------------------|---------------------------------------------------------------------------------|---------------------------|
| 1   | Elista                                    | 996,4                                                       | 996,4                                                                            | 9,6                       |
| 2   | Samara                                    | 9202,1                                                      | 9202,1                                                                          | 7,9                       |

As it can be seen from Table 1, in all cities under consideration (except Arkhangelsk and Vladimir) almost all domestic wastes were delivered to landfills without industrial reprocessing. In Arkhangelsk 16% of removed solid domestic wastes were reprocessed, in Vladimir - 5%.

It is worth noting that in 2002 in the Russian cities under consideration per capita volumes of solid domestic wastes were high enough. The specific value of the analyzed indicator ranged from 3 to 10 cubic meters per person. It is well known that the volume of solid domestic wastes formation is chiefly determined by standard of living of population. In 2012 in Moscow the volume of removed solid domestic wastes per capita amounted to 1,1 cubic meters, in St. Petersburg - to 1,5 cubic meters. The issue of dependence of the volumes of solid domestic wastes formation on standard of living of Russian urban population requires special consideration and analysis.

From 2005 to 2012 in all twenty cities under consideration there was an increase in the volume of removed solid domestic wastes (see Figure 6). The greatest growth for this period was observed in the top three leading cities in terms of the volume of solid domestic wastes, transported to landfills without industrial reprocessing: in Elista (six times), in Samara (four times) and in Irkutsk (three times). The increase in the volume of removed solid domestic wastes may indicate either a growth of city-dwellers' well-being, or an efficiency increase of public utilities supply, or an improvement in the quality of functioning of accounting and controlling wastes system. There may be other factors that require a special study in each particular city.
Table 3. Twenty Russian Cities with the Most Unfavourable Ecological Situation According to Three Considered Criteria.

| No. | The Most Polluted Cities of the Russian Federation, According to the Indicator (Criterion) | Total Emissions of Air Pollutants, tons per square kilometer of urban territory (as of 2012) | Volume of Contaminated Sewage Discharge, cubic meters per person (as of 2008) | Volume of Solid Domestic Wastes, Buried without Industrial Reprocessing, cubic meters per person (as of 2012) |

Russian cities with unfavourable ecological situation by three indicators (criteria) are presented in Table 3. There are some cities with unfavourable ecological situation according to the first two above-mentioned criteria simultaneously. These are Norilsk, Angarsk, Novokuznetsk, Magnitogorsk, Achinsk, Sterlitamak and Nizhny Tagil. In these cities negative impact on atmospheric air and surface water bodies is one of the strongest in comparison with other cities in Russia not included in the corresponding lists. This negative impact is chiefly induced by large industrial enterprises, located in these cities (see Table 4).

Table 4. Main Polluters in Russian Cities with the Most Unfavourable Ecological Situation According to Two of Three Considered Criteria.

| No. | City           | Main Sources of Pollution                                                                 |
|-----|----------------|------------------------------------------------------------------------------------------|
| 1   | Norilsk        | Polar Division of PJSC Mining and Metallurgical Company "Norilsk Nickel"               |
| 2   | Angarsk        | Number of factories of JSC "Angarsk petrochemical company", heat power plants, construction plants, PJSC "Sibreactiv", JSC "Angarsk Electrolysis Chemical Combine" |
| 3   | Novokuznetsk   | Plants of ferrous and non-ferrous metallurgy (first of all PJSC West-Siberian Metallurgical Combine, including West Siberian heat and power plant) |
| 4   | Magnitogorsk   | Plants of ferrous metallurgy (primarily PJSC "Magnitogorsk Iron and Steel Works")        |
| 5   | Achinsk        | PJSC "Achinsk Alumina Refinery", LLC "Achinsk Cement Plant", JSC "Achinsk Oil Refinery East Oil Company", enterprises for building materials production |
| 6   | Nizhny Tagil   | PJSC "Nizhniy Tagil Iron and Steel Works", JSC "Scientific and Production Corporation "Ural Carriage Works", PJSC "Uralchimplast", PJSC "Cryogenmash", LLC "Nizhnetagilsk plant of metal structures", PJSC "Nizhnetagilsk boiler-radiator plant" |
| 7   | Sterlitamak    | Plants of chemical industry (JSC "Sterlitamak Petrochemical Plant", JSC "Bashkir Soda Company") and mechanical engineering (JSC "Sterlitamak Machine Tool Enterprise") |

5. Discussion and Conclusion

The analysis of the approaches to the integrated assessment of environmental quality in Russian cities (the rating of sustainable development of Russian cities, the ecological rating of Russian cities), fulfilled in this research, showed that such assessments entail great difficulties with the collection of hard-to-access information, which is not always reflected in official statistical publications, and as a result they are often unrepresentative. Taking into account that, unlike regional statistics, municipal (urban) one has a very narrow set of indicators and different time series, the integrated assessments of environmental quality in Russian cities is not recommended for practice.

So within the bounds of this work ecological and economic analysis of Russian cities with the population of 100 thousand people or more was performed separately for different components of the urban environment: air, water and ground. This analysis made it possible to identify the cities with the most unfavourable environmental conditions. Norilsk, Angarsk, Novokuznetsk, Magnitogorsk, Achinsk, Nizhny Tagil and Sterlitamak were in the top 20 cities of Russia, which have the strongest negative impact on the state of atmospheric air (per square kilometer of urban area, as of 2012), and simultaneously in the top twenty Russian Cities, most intensively polluting surface water bodies (per inhabitant, as of 2008). Besides, from 2005 to 2012 in most Russian cities there was a total increase in the volume of the solid domestic wastes transported to landfills without industrial reprocessing.

The low quality of environment in these cities is largely due to natural and climatic conditions (bad conditions for contaminants dispersion) and specifics of their economic development: functioning of large industrial enterprises of ferrous and non-ferrous metallurgy, petrochemistry, construction industry. To improve the environmental quality in these cities comprehensive social, environmental and economic solutions are required.

The basis of environmental issues is socio-economic processes and phenomena. In the development strategies of these cities it should be recognized that the creation of favourable environmental conditions for cities’ dwellers is impossible without solving the problems of functioning of industrial enterprises located in these cities. Either a lot of financial resources should be spent to create an expensive system of treatment facilities at enterprises, or these enterprises should be relocated from the cities at a safe for urban environment distance and the problem of transport availability of these enterprises to their workers should be solved.
