A REFINED BEILINSON–BLOCH CONJECTURE
FOR MOTIVES OF MODULAR FORMS

MATTEO LONGO AND STEFANO VIGNI

Abstract. We propose a refined version of the Beilinson–Bloch conjecture for the motive associated with a modular form of even weight. This conjecture relates the dimension of the image of the relevant $p$-adic Abel–Jacobi map to certain combinations of Heegner cycles on Kuga–Sato varieties. We prove theorems in the direction of the conjecture and, in doing so, obtain higher weight analogues of results for elliptic curves due to Darmon.

1. Introduction

Let $N \geq 3$ be an integer, let $k \geq 4$ be an even integer and let $f \in S_k^\text{new}(\Gamma_0(N))$ be a normalized newform of weight $k$ and level $\Gamma_0(N)$, whose $q$-expansion will be denoted by

$$f(q) = \sum_{n \geq 1} a_n q^n.$$ 

Let $p \nmid N$ be a prime number and let $p \mid p$ be a prime ideal of the ring of integers $\mathcal{O}_F$ of the totally real field $F$ generated by the Fourier coefficients $a_n$ of $f$. Finally, let $K$ be a number field. To these data we may attach a $p$-adic Abel–Jacobi map

$$\text{AJ}_K : \text{CH}^{k/2}(\tilde{E}_{N}^{k-2}/K)_0 \otimes \mathcal{O}_F \to H^1_{f}(K, V_p)$$

where $F_p$ is the completion of $F$ at $p$, $\tilde{E}_{N}^{k-2}$ is the Kuga–Sato variety of level $N$ and weight $k$, $V_p$ is a twist of the $p$-adic representation attached to $f$ and $H^1_{f}(K, V_p)$ is its Bloch–Kato Selmer group over $K$ (here the subscript “$f$” stands for “finite” and should not be confused with the modular form $f$). The Beilinson–Bloch conjectures ([1], [11]) connect the values of the $L$-functions of algebraic varieties over number fields to global arithmetic properties of these varieties (see, e.g., [46] for an introduction). In particular, they state that the $F_p$-dimension of the image $X_p(K)$ of $\text{AJ}_K$ is equal to the order of vanishing of the complex $L$-function $L(f \otimes K, s)$ of $f$ over $K$ at its center of symmetry $s = k/2$. Moreover, if $\tilde{\rho}_p$ denotes this dimension then the leading term of the derivative of order $\tilde{\rho}_p$ of $L(f \otimes K, s)$ at $s = k/2$ is predicted up to multiplication by elements of $\mathbb{Q}^\times$. When $K$ is an imaginary quadratic field of discriminant coprime to $Np$ or $K = \mathbb{Q}$, important results towards this conjecture (at least in low rank situations) have been obtained by combining Nekovár’s generalization of Kolyvagin’s theory to Chow groups of Kuga–Sato varieties ([35]) with Zhang’s formula of Gross–Zagier type for higher weight modular forms ([49]). More recently, the Beilinson–Bloch conjectures have been subsumed within the Tamagawa number conjecture of Bloch and Kato ([12]), which predicts (by using Fontaine’s theory of $p$-adic representations) the value of the non-zero rational factor that was not made explicit in the original conjectures.

The goal of the present article is to investigate refined – or equivariant – analogues of these conjectures in which, roughly speaking, $L$-functions are replaced by Heegner cycles.

To better explain our work, let us recall that refined versions of the Birch and Swinnerton-Dyer conjecture (BSD conjecture, for short) for a rational elliptic curve $E$ were first proposed by Mazur and Tate in [33]. In that article, the role of $L$-functions was played by certain
combinations of modular symbols with coefficients in the group algebra \( \mathbb{Q}[[\text{Gal}(\mathbb{Q}(\zeta_M)/\mathbb{Q})]] \), called “theta elements” and denoted by \( \theta_{E,M} \); here \( M \geq 1 \) is an integer and \( \zeta_M \) is a primitive \( M \)-th root of unity. The Mazur–Tate refined conjecture of BSD type states that \( \theta_{E,M} \) belongs to a power \( r \) of the augmentation ideal \( I \) of \( \mathbb{Q}[[\text{Gal}(\mathbb{Q}(\zeta_M)/\mathbb{Q})]] \) that can be predicted in terms of the rank of the Mordell–Weil group \( E(\mathbb{Q}) \) and the number of primes of split multiplicative reduction for \( E \) dividing \( M \). This conjecture describes also the leading value of \( \theta_{E,M} \), which is defined as the image of \( \theta_{E,M} \) in the quotient \( I^r/I^{r+1} \). Extensions and analogues of this conjecture for Artin \( L \)-functions and for \( L \)-functions of more general motives have also been formulated, and partial results have been proved (see, e.g., [14], [15], [20], [22], [43] and the references therein).

Moving from [33] and the observation that modular symbols and Heegner points enjoy similar formal properties, Darmon proposed in [15] refined versions à la Mazur–Tate of the BSD conjecture, where modular symbols are replaced by Heegner points. Later on, Bertolini and Darmon began the systematic study of \( p \)-adic analogues of the BSD conjecture in which the relevant \( p \)-adic \( L \)-functions are defined in terms of distributions of Heegner (and Gross–Heegner) points on Shimura curves attached either to definite or to indefinite quaternion algebras (see [4], [5], [6], [7], [8]).

Our aim in this paper is to formulate and study refined versions of the Beilinson–Bloch conjecture for the motive associated with the modular form \( f \); in this context, the role of the Heegner points appearing in [15] is played by higher-dimensional Heegner cycles in the sense of Nekovář ([35]). We hope that our work, offering an equivariant refinement of the above mentioned conjectures in which the complex \( L \)-function of a modular form is replaced by an algebraically defined one, can be viewed as complementary to the results of Burns and of Burns–Flach on Stark’s conjectures and Tamagawa numbers of motives (see, e.g., [14], [13]).

In order to state our main results more precisely, we need some notation. Let \( K \) be an imaginary quadratic field of discriminant coprime to \( Np \) in which all the primes dividing \( N \) split, let \( T \) be a square-free product of primes that are inert in \( K \) and do not divide \( Np \) and let \( K_T \) be the ring class field of \( K \) of conductor \( T \). Write \( \mathcal{O}_p \) for the completion of \( \mathcal{O}_F \) at \( p \). As recalled in [2.1] and [2.3] there is a natural way to introduce an \( \mathcal{O}_p \)-lattice \( A_p \) inside \( V_p \), and to all these data we may attach a Heegner cycle \( y_{T,p} \in \Lambda_p(K_T) \subset H^1_{\text{cont}}(K_T, \mathcal{O}_p) \) where \( \Lambda_p(K_T) \) is the image of the \( \mathcal{O}_p \)-integral version of the Abelian–Jacobi map \( \mathcal{A}_{K_T} \) and \( H^1_{\text{cont}} \) denotes continuous cohomology (see [2.3] and [3.1]). Set \( G_T := \text{Gal}(K_T/K) \) and \( \Gamma_T := \text{Gal}(K_T/K) \), consider the theta element

\[
\theta_{T,p} := \sum_{\sigma \in G_T} \sigma(y_{T,p}) \otimes \sigma \in \Lambda_p(K_T) \otimes_{\mathcal{O}_p} \mathcal{O}_p[G_T]
\]

and let \( \theta_{T,p}^* \) be the image of \( \theta_{T,p} \) via the involution sending \( \sigma \in G_T \) to \( \sigma^{-1} \). Taking suitable trace-like operators to \( K \) we obtain elements \( \zeta_{T,p} \) and \( \zeta_{T,p}^* \) that may be naturally viewed as belonging to \( \Lambda_p(K_S) \otimes_{\mathcal{O}_p} \mathcal{O}_p[\Gamma_S] \) whenever \( T | S \).

Now let \( S \) be a square-free product of primes that are inert in \( K \) and do not divide \( Np \), then define the arithmetic \( L \)-function attached to \( S \) and \( p \) as

\[
\mathcal{L}_{S,p} := \left( \sum_{T | S} a_T \zeta_{T,p} \right) \otimes \left( \sum_{T | S} a_T^* \zeta_{T,p}^* \right) \in \Lambda_p(K_S) \otimes_{\mathcal{O}_p} \mathcal{O}_p[\Gamma_S],
\]

where \( a_T \) and \( a_T^* \) are explicit elements of \( \mathcal{O}_p[\Gamma_S] \) that are defined in [33] below in terms of the Möbius function and the quadratic character of \( K \).

The finite-dimensional \( \mathbb{F}_p \)-vector space \( X_p(K) \) splits under the action of the non-trivial element of \( \text{Gal}(K/\mathbb{Q}) \) as a direct sum

\[
X_p(K) = X_p(K)^+ \oplus X_p(K)^-
\]
of its eigenspaces. Set $\rho_p^+ := \dim_{\mathcal{F}_p} (X_p(K)^{\pm})$ and

$$\rho_p := \begin{cases} \max\{\rho^+_p, \rho^-_p\} - 1 & \text{if } \rho^+_p \neq \rho^-_p, \\ \rho^+_p = \rho^-_p & \text{otherwise.} \end{cases}$$

As a consequence of the Beilinson–Bloch conjecture, the function $p \mapsto \rho_p$ is expected to be constant and, since the order of vanishing of $L(f \otimes K, s)$ at $s = k/2$ is odd, the case $\rho^+_p = \rho^-_p$ should never occur. Let $I_{\Gamma_S}$ be the augmentation ideal of $\mathcal{O}_p[I_S]$ (to simplify our notation, we suppress dependence on $p$). Finally, write $J(S)$ for the cokernel of the map

$$H^1_f(K, A_p/pA_p) \longrightarrow \bigoplus_{\ell \mid S} H^1_f(K_\lambda, A_p/pA_p)$$

where $K_\lambda$ is the completion of $K$ at the unique prime $\lambda$ above $\ell$. Our results apply to all prime numbers $p$ outside a finite set $\Sigma$ that we introduce in [35] in fact, one crucial feature that we require of the prime $p$ is that the Galois representation attached to $A_p$ is irreducible with non-solvable image.

**Theorem 1.1.** Let $p$ be a prime number such that $p \notin \Sigma$, let $S$ be a product of primes that are inert in $K$ and do not divide $Np$, and let $p$ be a prime ideal of $\mathcal{O}_F$ above $p$.

1. $\mathcal{L}_{S,p} \in \mathcal{A}_p(\mathcal{K}_S)^{\otimes 2} \otimes \mathcal{O}_p H^{2p}_{\Gamma_S}$.
2. Suppose that $p \mid \ell + 1$ for all prime numbers $\ell \mid S$. If $|\rho^+_p - \rho^-_p| = 1$ then the image $\tilde{\mathcal{L}}^{(p)}_{S,p}$ of $\mathcal{L}_{S,p}$ in

$$(\mathcal{A}_p(\mathcal{K}_S)^{\otimes 2}/p\mathcal{A}_p(\mathcal{K}_S)^{\otimes 2}) \otimes \mathcal{O}_p (I^{2p}_{\Gamma_S}/I^{2p+1}_{\Gamma_S})$$

belongs to the natural image of

$$(\mathcal{A}_p(\mathcal{K})^{\otimes 2}/p\mathcal{A}_p(\mathcal{K})^{\otimes 2}) \otimes \mathcal{O}_p (I^{2p}_{\Gamma_S}/I^{2p+1}_{\Gamma_S}).$$

3. Assume that $p \mid \ell + 1$ for all prime numbers $\ell \mid S$ and that the $p$-part $\Pi_p(f/K)$ of the Shafarevich–Tate group of $f$ over $K$ is finite. If $|\rho^+_p - \rho^-_p| = 1$ and $p$ divides $|\Pi_p(f/K)| \cdot |J(S)|$ then $\tilde{\mathcal{L}}^{(p)}_{S,p} = 0$.

Theorem [11] which corresponds to Corollary [12] in the main body of the text, provides a higher weight analogue of a theorem of Darmon for elliptic curves over $\mathbb{Q}$ ([15]), and at the same time can be viewed as a partial result towards a refined Beilinson–Bloch conjecture for modular forms. This perspective is addressed in the last part of the paper (Section 5), where we relate $\mathcal{L}_{S,p}$ to an axiomatic theory of regulators of Mazur–Tate type in this setting. The conjectural picture motivating Theorem [11] is stated as Question [5.2]. We believe that these regulators can be explicitly defined using Nekovář’s theory of $p$-adic height pairings ([36]), and we plan to come back to these issues in a subsequent paper.

We conclude by remarking that Theorem [11] is a consequence of analogous results for the elements $\zeta_{S,p}$ (Theorem [4.11]). It is worth pointing out that all these results are based on a congruence property enjoyed by Heegner cycles (Theorem [3.33]): namely, generalized Kolyvagin derivatives (called Darmon–Kolyvagin derivatives in this article and studied in [3.31]) of Heegner cycles are zero modulo $p^n$ if their order is less than the $\mathcal{O}_p/p^n\mathcal{O}_p$-rank of $H^1_f(K, A_p/p^nA_p)$. As a by-product of Theorem [3.33] if $p$ is a prime not dividing $N$, inert in $K$ and such that $p \mid \ell + 1$ then in Theorem [4.11] we give a bound (in terms of $p$ and the dimension of $H^1_f(K, A_p/pA_p)$ over $\mathcal{O}_p/p\mathcal{O}_p$ on the $\mathcal{O}_p/p\mathcal{O}_p$-dimension of the Galois module generated by Heegner cycles inside $\mathcal{L}_p(K_\ell)/p\mathcal{L}_p(K_\ell)$.
Notation and conventions. Unless specified otherwise, unadorned tensor products \( \otimes \) are taken over \( \mathbb{Z} \).

The cardinality of a (finite) set \( X \) is denoted either by \( \# X \) or by \( |X| \), according to convenience.

If \( K \) is a field then set \( G_K := \text{Gal}(\overline{K}/K) \), where \( \overline{K} \) is a fixed algebraic closure of \( K \). For any continuous \( G_K \)-module \( M \) let \( H^i(K, M) \) denote the \( i \)-th cohomology group of \( G_K \) with coefficients in \( M \). If \( K/F \) is a field extension then

\[
\text{res}_{K/F} : H^i(F, M) \to H^i(K, M), \quad \text{cores}_{K/F} : H^i(K, M) \to H^i(F, M)
\]
denote the restriction and corestriction maps in cohomology, respectively. Recall that for \( K/F \) finite and Galois there is an equality

\[
\text{res}_{K/F} \circ \text{cores}_{K/F} = N_{K/F}
\]

where \( N_{K/F} := \sum_{\sigma \in \text{Gal}(K/F)} \sigma \) is the Galois norm (or trace) operator acting on \( H^i(K, M) \).

Fix algebraic closures \( \overline{Q} \) of \( Q \) and \( \overline{Q}_{\ell} \) of \( Q_{\ell} \) for any prime number \( \ell \), and then fix field embeddings \( \overline{Q} \hookrightarrow \overline{Q}_{\ell} \) for every \( \ell \). Let \( \overline{Q}_{\ell}^{nr} \) be the maximal unramified extension of \( Q_{\ell} \) inside \( \overline{Q}_{\ell} \) and write \( F_{\ell} \) for the arithmetic Frobenius in \( \text{Gal}(\overline{Q}_{\ell}^{nr}/Q_{\ell}) \). With an abuse of notation, when dealing with a \( G_{\overline{Q}} \)-module that is unramified at \( \ell \) we shall often adopt the same symbol to denote a lift of \( F_{\ell} \) to \( G_{\overline{Q}_{\ell}} \) (and its image in \( G_{\overline{Q}} \)).

Finally, if \( L/E \) is a Galois extension of number fields, \( \lambda \) is a prime of \( E \) that is unramified in \( L \) and \( \lambda' \) is a prime of \( L \) above \( \lambda \) then \( \text{Frob}_{\lambda'/\lambda} \in \text{Gal}(L/E) \) denotes the Frobenius substitution at \( \lambda' \); the conjugacy class of \( \text{Frob}_{\lambda'/\lambda} \) in \( \text{Gal}(L/E) \) will be denoted by \( \text{Frob}_{\lambda} \) (notation not reflecting dependence on \( L \)).

Acknowledgements. It is a pleasure to thank Jan Nekovář for enlightening conversations on some of the topics of this paper.

2. Beilinson–Bloch conjecture for modular forms

In this section \( f \in S_k(\Gamma_0(N)) \) is a normalized newform of (even) weight \( k \) and level \( \Gamma_0(N) \) and \( p \) is a prime number such that \( p \nmid 2N(k-2)!\phi(N) \), where \( \phi \) is Euler’s function.

Remark 2.1. For the arguments developed in this section, a more natural choice of \( p \) would simply require that \( p \nmid 2N \) and \( p > k - 1 \), as explained in [35, §6.5]. However, in this case the notation becomes more complicated and some neatly stated results, for instance [35, Proposition 2.1], require substantial modifications to make them consistent. In order to emphasize the new aspects of our work without indulging in unenlightening technicalities, we therefore decided to work under the above simplifying assumption.

2.1. Galois representations. Denote by \( Y_N \) the affine modular curve over \( \overline{Q} \) of level \( \Gamma(N) \), whose complex points are given by \( Y_N(\mathbb{C}) = \Gamma(N)\backslash \mathcal{H} \) where \( \mathcal{H} \) is the upper half plane. Let \( j : Y_N \hookrightarrow X_N \) be the proper smooth compactification of \( Y_N \).

For any integer \( n \geq 1 \) define the sheaves

\[
\mathcal{F}_n := \text{Sym}^{k-2}(R^1\pi_*\mathbb{Z}/p^n\mathbb{Z})/(k/2-1), \quad \mathcal{F} := \varprojlim_n \mathcal{F}_n
\]

(both \( \mathcal{F} \) and \( \mathcal{F}_n \) depend on \( p \), but we suppress this dependence to simplify notations).

Let \( B := \Gamma(N)/\Gamma_0(N) \), consider the projector \( \Pi_B := (\#B)^{-1}\sum_{b \in B} b \in \mathbb{Z}_p[B] \) and define

\[
J_p := \Pi_B H_B^{1}(X_N \otimes \overline{Q}, j_*\mathcal{F})(k/2).
\]

Denote by \( T \) the Hecke algebra generated over \( \mathbb{Z} \) by the standard Hecke operators \( T_\ell \) for primes \( \ell \nmid N \). Let \( \theta_f : T \to \mathcal{O}_F \) be the morphism associated with \( f \), where \( F \) is the totally real number field generated over \( \overline{Q} \) by the Fourier coefficients of \( f \) and \( \mathcal{O}_F \) is its ring of integers.
The Hecke algebra $\mathbb{T}$ acts on $J_p$, as explained in [35, pp. 101–102]. Set $I_f := \ker(\theta_f)$ and define

$$A_p := \{x \in J_p \mid I_f \cdot x = 0\}.$$ 

Then $A_p$, which should be regarded as a higher weight analogue of the Tate module of an abelian variety, is equipped with a continuous $O_F$-linear action of the absolute Galois group $G_{\overline{Q}} := \text{Gal}(\overline{Q}/Q)$ and is (isomorphic to) the $k/2$-twist of the representation attached to $f$ by Deligne ([19]). More precisely, $A_p$ is a free $O_F \otimes \mathbb{Z}_p$-module of rank 2 such that for every prime $\ell \nmid Np$ the arithmetic Frobenius $F_\ell$ at $\ell$ acting on $A_p$ satisfies

$$\det(1 - F_\ell X | A_p) = 1 - \frac{a_\ell}{\ell - 1}X + \ell X^2.$$ 

As pointed out in [35, p. 102], there is a map $J_p \to A_p$ that is both $T$-equivariant and $G_{\overline{Q}}$-equivariant.

2.2. Kuga–Sato varieties. In this subsection we briefly recall basic definitions and facts about Kuga–Sato varieties, along the lines of [19], [35, §2], [37, §1] (see also [9, Appendix A] by Conrad for a generalization to the relative situation).

Let $\pi : \mathcal{E}_N \to Y_N$ be the universal elliptic curve and $\bar{\pi} : \tilde{\mathcal{E}}_N \to X_N$ the universal generalized elliptic curve, which is proper but not smooth. Define

$$\bar{\pi}_{k-2} : \tilde{\mathcal{E}}_{N}^{k-2} \longrightarrow X_N$$

to be the fiber product of $k - 2$ copies of $\tilde{\mathcal{E}}_N$ over $X_N$. If $k \geq 4$ then $\tilde{\mathcal{E}}_{N}^{k-2}$ is singular and we call its canonical desingularization $\mathcal{E}_{N}^{k-2}$ constructed by Deligne ([19]) the Kuga–Sato variety of level $N$ and weight $k$.

The level $N$ structure on $\mathcal{E}_N$ induces a homomorphism $(\mathbb{Z}/N\mathbb{Z})^2 \times X_N \to \mathcal{E}_N$ of group schemes over $X_N$, where $\mathcal{E}_N$ is the Néron model of $\mathcal{E}_N$ over $X_N$. Therefore $(\mathbb{Z}/N\mathbb{Z})^2$ acts by translations on $\mathcal{E}_N$. Moreover, $\mathbb{Z}/2\mathbb{Z}$ acts as multiplication by $-1$ in the fibers, and this gives an action of $(\mathbb{Z}/N\mathbb{Z})^2 \times (\mathbb{Z}/2\mathbb{Z})$ on $\mathcal{E}_N$. Finally, the symmetric group $S_{k-2}$ on $k - 2$ letters acts on $\mathcal{E}_{N}^{k-2}$ by permutation of the factors, and this gives an action of

$$\Gamma_{k-2} := ((\mathbb{Z}/N\mathbb{Z})^2 \times (\mathbb{Z}/2\mathbb{Z}))^{k-2} \rtimes S_{k-2}$$
on $\mathcal{E}_{N}^{k-2}$ by automorphisms on the fibers of $\pi_{k-2}$, which extends canonically to an action of $\Gamma_{k-2}$ on $\tilde{\mathcal{E}}_{N}^{k-2}$.

Now define the homomorphism $\epsilon : \Gamma_{k-2} \to \{-1\}$ to be trivial on $(\mathbb{Z}/N\mathbb{Z})^{2(k-2)}$, the product map on $(\mathbb{Z}/2\mathbb{Z})^{k-2}$ and the sign character on $S_{k-2}$. Finally, let

$$\Pi_\epsilon \in \mathbb{Z}[1/2N(k-2)!][\Gamma_{k-2}]$$

be the projector associated with $\epsilon$.

Then, by [35, Proposition 2.1] (see also [37, Theorem 1.2.1] and [37, II, Proposition 2.4] for the analogous result with coefficients in $\mathbb{Q}_p$), we have

$$H^1_{\text{ét}}(X_N \otimes \overline{Q}, j_* \mathcal{F}_n)(1) = \Pi_\epsilon H^{k-1}_{\text{ét}}(\tilde{\mathcal{E}}_{N}^{k-2} \otimes \overline{Q}, \mathbb{Z}/p^n\mathbb{Z})(k/2).$$

Furthermore, thanks to [35, Lemma 2.2], we know that $H^1_{\text{ét}}(X_N, j_* \mathcal{F})$ is torsion free and that $H^1_{\text{ét}}(X_N, j_* \mathcal{F}/p^m j_* \mathcal{F})$ is canonically isomorphic to $H^1_{\text{ét}}(X_N, j_* \mathcal{F})/p^m H^1_{\text{ét}}(X_N, j_* \mathcal{F})$, for all integers $m \geq 1$. Combining these facts we obtain a map

$$H^{k-1}_{\text{ét}}(\tilde{\mathcal{E}}_{N}^{k-2} \otimes \overline{Q}, \mathbb{Z}/p^n\mathbb{Z})(k/2) \longrightarrow J_p \longrightarrow A_p$$

that factors through $\Pi_\epsilon H^{k-1}_{\text{ét}}(\tilde{\mathcal{E}}_{N}^{k-2} \otimes \overline{Q}, \mathbb{Z}/p^n\mathbb{Z})(k/2)$.
2.3. Abel–Jacobi maps. Fix a field $L$ of characteristic 0, denote by $\bar{L}$ an algebraic closure of $L$ and let

$$\Phi_{p,L} : CH^{k/2}(\hat{\mathcal{E}}_{N}^{k-2}/L)_0 \longrightarrow H_{\text{cont}}^1(L, H^{k-1}_{\text{ét}}(\hat{\mathcal{E}}_{N}^{k-2} \otimes \bar{L}, \mathbb{Z}_p(k/2)))$$

be the $p$-adic Abel–Jacobi map (see [24, §9]). Here $CH^{k/2}(\hat{\mathcal{E}}_{N}^{k-2}/L)_0$ is the group of homologically trivial cycles of codimension $k/2$ on $\hat{\mathcal{E}}_{N}^{k-2}$ defined over $L$ modulo rational equivalence and $H_{\text{cont}}^1$ denotes continuous cohomology. Equivalently,

$$CH^{k/2}(\hat{\mathcal{E}}_{N}^{k-2}/L)_0 = \ker \left(CH^{k/2}(\hat{\mathcal{E}}_{N}^{k-2}/L) \longrightarrow H_{\text{ét}}^k(\hat{\mathcal{E}}_{N}^{k-2} \otimes \bar{L}, \mathbb{Z}_p(k/2))\right),$$

where $CH^{k/2}(\hat{\mathcal{E}}_{N}^{k-2}/L)$ is the group of cycles of codimension $k/2$ on $\hat{\mathcal{E}}_{N}^{k-2}$ defined over $L$ modulo rational equivalence. Indeed, using the Lefschetz principle and comparison isomorphisms between étale and singular cohomology over $\mathbb{C}$, it can be proved that the right hand side of \ref{eq:abel-jacobi-map} does not depend on $p$ (see, e.g., [38, §1.3] for details).

Composing \ref{eq:abel-jacobi-map} and \ref{eq:abel-jacobi-map-extension} and extending $\mathbb{Z}_p$-linearly, we get a map

$$AJ_{f,p,L} : CH^{k/2}(\hat{\mathcal{E}}_{N}^{k-2}/L)_0 \otimes \mathbb{Z}_p \longrightarrow H_{\text{cont}}^1(L, A_p).$$

Now we localize (or, rather, complete) the representation $A_p$ at a prime ideal $\mathfrak{p}$ of $\mathcal{O}_F$ dividing $p$. More precisely, if $\mathfrak{p}$ is such a prime then denote by $\mathcal{O}_\mathfrak{p}$ the completion of $\mathcal{O}_F$ at $\mathfrak{p}$ and set $A_p := A_p \otimes \mathcal{O}_F \otimes \mathbb{Z}_p$, which is a free $\mathcal{O}_\mathfrak{p}$-module of rank 2 equipped with a $G_\mathfrak{p}$-action. It follows that $A_p = \prod_{\mathfrak{p} \mid p} A_{\mathfrak{p}}$, the product being taken over all prime ideals of $\mathcal{O}_F$ above $p$. Fix once and for all a prime ideal $\mathfrak{p}$ as above. Composing the map $AJ_{f,p,L}$ introduced in \ref{eq:abel-jacobi-map} with the one induced by the canonical projection $A_p \twoheadrightarrow A_p$, we get an $\mathcal{O}_\mathfrak{p}$-linear map

$$AJ_{f,p,L} : CH^{k/2}(\hat{\mathcal{E}}_{N}^{k-2}/L)_0 \otimes \mathcal{O}_\mathfrak{p} \longrightarrow H_{\text{cont}}^1(L, A_p).$$

If $L$ is a Galois extension of $L'$ then $AJ_{f,p,L}$ is $\text{Gal}(L/L')$-equivariant with respect to the natural Galois actions on domain and codomain ([35, Proposition 4.2]). For simplicity, from here on we write $AJ_L$ for $AJ_{f,p,L}$, understanding that we are fixing a prime $\mathfrak{p}$ of $F$ above $p$.

Finally, let us introduce another map that will be used in \ref{sec:selmer-groups}. Since the Abel–Jacobi map commutes with automorphisms of the underlying variety, the map $AJ_{f,p,L}$ in \ref{eq:abel-jacobi-map} factors through

$$\Pi_{\mathfrak{p}} \left(CH^{k/2}(\hat{\mathcal{E}}_{N}^{k-2}/L)_0 \otimes \mathbb{Z}_p\right) = \Pi_{\mathfrak{p}} \left(CH^{k/2}(\hat{\mathcal{E}}_{N}^{k-2}/L) \otimes \mathbb{Z}_p\right):$$

the equality follows from [35, Prop. 2.1], see also [35, p. 105]. Thus \ref{eq:abel-jacobi-map} yields a map

$$\Psi_{f,p,L} : \Pi_{\mathfrak{p}} \Pi_{\mathfrak{q}} \left(CH^{k/2}(\hat{\mathcal{E}}_{N}^{k-2}/L) \otimes \mathcal{O}_\mathfrak{p}\right) \longrightarrow H_{\text{cont}}^1(L, A_p).$$

This map is $\mathbb{T}$-equivariant and if $L$ is Galois over $\mathbb{Q}$ then it is $\text{Gal}(L/\mathbb{Q})$-equivariant as well (use [35, Proposition 4.2] and apply the projection $A_p \twoheadrightarrow A_p$, which is both $\mathbb{T}$- and $\text{Gal}(L/\mathbb{Q})$-equivariant).

2.4. Selmer groups. Let $E$ be a number field and denote by $G_E := \text{Gal}(E/E)$ its absolute Galois group. Let $V$ be a $p$-adic representation of $G_E$ unramified outside a finite set $\Xi$ of places of $E$ containing all the archimedean primes and the primes above $p$. If $v$ is a prime of $E$ above $p$ then, as in [12, Sections 3 and 5], define

$$H^1_f(E_v, V) := \ker \left(H_{\text{cont}}^1(E_v, V) \longrightarrow H_{\text{cont}}^1(E_v, V \otimes \mathbb{Q}_p B_{\text{cris}})\right),$$

where $B_{\text{cris}}$ is Fontaine’s crystalline ring of periods (see, e.g., [12, Section 1], and do not confuse the subscript “$f$” in $H^1_f$ with our fixed modular form $f$). If $v$ is a prime of $E$ not dividing $p$ then write $I_v := \text{Gal}(E_v/E_v^{ur})$ for the inertia subgroup of $\text{Gal}(E_v/E_v)$, where $E_v^{ur}$
denotes the maximal unramified extension of $E_v$. The unramified cohomology of $V$ at $v$ is defined as
\[ H^1_{\text{ur}}(E_v, V) := H^1_{\text{cont}}(\text{Gal}(E_v^\text{ur}/E_v), V) \]
the isomorphism coming from the inflation-restriction exact sequence (i.e., the exact sequence of low degree terms in the relevant Hochschild–Serre spectral sequence). Finally, for such a prime $v$ of $E$ set
\[ H^1_j(E, V) := H^1_{\text{ur}}(E_v, V). \]

**Definition 2.2.** The Bloch–Kato Selmer group $H^1_j(E, V)$ is the $\mathbb{Q}_p$-subspace of $H^1_{\text{cont}}(E, V)$ consisting of those classes whose localizations lie in $H^1_j(E_v, V)$ for all primes $v$ of $E$.

Let $G_{E, \Xi}$ denote the Galois group over $E$ of the maximal extension of $E$ unramified outside $\Xi$; then $V$ is a representation of $G_{E, \Xi}$ and $H^1_j(E, V)$ is a subspace of the finite-dimensional $\mathbb{Q}_p$-vector space $H^1_{\text{cont}}(G_{E, \Xi}, V)$, hence $H^1_j(E, V)$ has finite dimension over $\mathbb{Q}_p$.

Now we specialize the previous discussion to the case where
\[ V = H^{k-1}_{\text{et}}(\hat{\mathcal{E}}^2_N \otimes \bar{E}, \mathbb{Q}_p(k/2)). \]
It is well known that $V$ is unramified outside the primes of $E$ dividing $Np$; in light of this, from here on we take
\[ \Xi := \{v \text{ place of } E \mid v \nmid Np \text{ or } v \mid \infty \}. \]

**Remark 2.3.** With $V$ as in (9), the Selmer group $H^1_j(E, V)$ of Definition 2.2 is equal to the one originally defined in [12] and later studied, e.g., by Besser in [10]. In particular, it is smaller than the group considered by Nekovář in [35]; this is due to the fact that no local conditions at the places of $E$ dividing $N$ are imposed in [35] (c.f. [35, p. 118]).

Let
\[ \Phi_{p,E} : \text{CH}^{k/2}(\hat{\mathcal{E}}^2_N/E) \otimes \mathbb{Q}_p \rightarrow H^1_{\text{cont}}(E, H^{k-1}_{\text{et}}(\hat{\mathcal{E}}^2_N \otimes \bar{E}, \mathbb{Q}_p(k/2))) \]
be the map induced by the Abel–Jacobi map in [4].

**Theorem 2.4** (Niziol, Nekovář, Saito). There is an inclusion
\[ \text{im}(\Phi_{p,E} \otimes \mathbb{Q}_p) \subset H^1_j(E, H^{k-1}_{\text{et}}(\hat{\mathcal{E}}^2_N \otimes \bar{E}, \mathbb{Q}_p(k/2))). \]
In particular, $\text{im}(\Phi_{p,E} \otimes \mathbb{Q}_p)$ is a finite-dimensional vector space over $\mathbb{Q}_p$.

**Proof.** Let $v$ be a prime of $E$ and, for simplicity, set
\[ V_v := H^{k-1}_{\text{et}}(\hat{\mathcal{E}}^2_N \otimes \bar{E}_v, \mathbb{Q}_p(k/2)). \]
We need to show that there is an inclusion
\[ \text{im}(\Phi_{p,E_v} \otimes \mathbb{Q}_p) \subset H^1_j(E_v, V_v), \]
where the map $\Phi_{p,E_v} \otimes \mathbb{Q}_p$ is defined as in [11] with $E$ replaced by $E_v$. If $v \nmid p$ then the weight-monodromy conjecture ([15, p. 238]) is known to hold for compactified Kuga–Sato varieties over $E_v$ ([11], [42]), and so $H^1_{\text{cont}}(E_v, V_v) = 0$ by [38, Proposition 2.5]. On the other hand, if $v \mid p$ then $\hat{\mathcal{E}}^2_N$ has good reduction at $v$ (recall that $\hat{\mathcal{E}}^{k-2}_N$ has good reduction outside $N$ and $p \nmid N$), hence $\text{im}(\Phi_{p,E_v} \otimes \mathbb{Q}_p) \subset H^1_j(E_v, V_v)$ by [11, Theorem 3.2]. Finally, the last assertion follows from the finite dimensionality over $\mathbb{Q}_p$ of the right hand side of (12). \hfill $\Box$

**Remark 2.5.** The result used above was proved in [41] under a projectivity assumption on the relevant algebraic varieties, but this stronger condition can be dispensed with, as explained in [38, Theorem 3.1].
We will now consider Selmer groups of $A_p$ and of quotients of it, and use Theorem 2.3 to describe them. For simplicity, assume that the prime number $p$ does not ramify in $F$. Define the $F_p$-vector space $V_p := A_p \otimes \mathbb{Q}_p$. For every integer $m \geq 1$ define $W_p := A_p \otimes \mathbb{Q}_p / \mathbb{Z}_p$, so that $W_p[p^m] = A_p/p^m A_p$. For any place $v$ of $E$ there are maps
\[ \varphi_v : H^1(E_v, A_p) \to H^1(E_v, V_p) \quad \text{and} \quad \pi_v : H^1(E_v, A_p) \to H^1(E_v, W_p[p^m]) \]
induced by the canonical arrows $A_p \to V_p$ and $A_p \to W_p[p^m]$. Set
\[ H^1_v(E_v, A_p) := \varphi_v^{-1}(H^1(E_v, V_p)) \quad \text{and} \quad H^1_v(E_v, W_p[p^m]) := \pi_v(H^1(E_v, A_p)). \]

In the following definition $M$ denotes either $A_p$ or $W_p[p^m]$.

**Definition 2.6.** The Bloch–Kato Selmer group $H_f^1(E, M)$ of $M$ over $E$ is the subgroup of $H_{\text{cont}}^1(E, M)$ consisting of the classes whose localizations lie in $H^1_f(E_v, M)$ for all $v$.

If $\Xi$ is as in (10) then $A_p$ is a $G_{E, \Xi}$-module and $H^1_f(E, W_p[p^m])$ is a subgroup of the finite group $H^1(G_{E, \Xi}, W_p[p^m])$, hence $H^1_f(E, W_p[p^m])$ is a finite $\mathcal{O}_p/p^m \mathcal{O}_p$-module.

As in (10), set $V := H^1_{\overline{k}-1}(\widehat{\mathcal{E}}^k_{N}/E, \mathbb{Q}_p(k/2))$. To clarify the various relations between Abel–Jacobi maps and Selmer groups, observe that there is a commutative diagram

\[
\begin{array}{ccc}
\text{CH}^{k/2}(\widehat{\mathcal{E}}^k_{N}/E) \otimes \mathbb{Q}_p & \xrightarrow{\Phi_{p,E} \otimes \mathbb{Q}_p} & H^1_f(E, V) \\
\downarrow & & \downarrow \lambda \\
\text{CH}^{k/2}(\widehat{\mathcal{E}}^k_{N}/E) \otimes F_p & \xrightarrow{A_{E,F}} & H^1_{\text{cont}}(E, V_p) \\
\downarrow & \varphi & \downarrow \\
\text{CH}^{k/2}(\widehat{\mathcal{E}}^k_{N}/E) \otimes \mathcal{O}_p & \xrightarrow{A_{E}} & H^1_{\text{cont}}(E, A_p) \\
\downarrow & \varpi & \downarrow \\
\text{CH}^{k/2}(\widehat{\mathcal{E}}^k_{N}/E) \otimes (\mathcal{O}_p/p^m \mathcal{O}_p) & \xrightarrow{A_{E,m}} & H^1_{\text{cont}}(E, W_p[p^m]) \\
\end{array}
\]

where

- the map $\lambda$ comes from the map $V \to V_p$ induced by the map $V \to A_p$ in (3) by projecting from $A_p$ onto $A_p$ and then composing with the inclusion $A_p \hookrightarrow V_p$;
- the maps $\varphi$ and $\varpi$ are induced by $A_p \to V_p$ and $A_p \to W_p[p^m]$, respectively;
- the unlabeled vertical arrows are induced by the natural maps $\mathcal{O}_p \hookrightarrow F_p$, $\mathcal{O}_p \hookrightarrow F_p$ and $\mathcal{O}_p \hookrightarrow \mathcal{O}_p/p^m \mathcal{O}_p$;
- the maps $A_{E,F}$ and $A_{E,m}$ are induced by multiplication by elements of $F_p$ and $\mathcal{O}_p/p^m \mathcal{O}_p$, respectively.

**Corollary 2.7.** There are inclusions

1. $\text{im}(A_{E,F}) \subset H^1_f(E, V_p)$;
2. $\text{im}(A_{E}) \subset H^1_f(E, A_p)$;
3. $\text{im}(A_{E,m}) \subset H^1_f(E, W_p[p^m])$.

In particular, the $F_p$-vector space $\text{im}(A_{E,F})$ has finite dimension.

**Proof.** All the inclusions follow easily from the definitions and the commutativity of diagram (13). To check the last assertion, note that $H^1_f(E, V_p)$ is finite-dimensional over $F_p$ because $V_p$ is unramified outside the finite set $\Xi$ introduced in (10).
For any number field $E$ define

$$
\Lambda_p(E) := \text{im}(\text{AJ}_E) \subset H^1_f(E, A_p)
$$

and

$$
X_p(E) := \varphi(\Lambda_p(E)) \otimes_{O_p} F_p \subset H^1_f(E, V_p).
$$

If $E$ is Galois over $\mathbb{Q}$ then $\Lambda_p(E)$ and $X_p(E)$ are equipped with $\text{Gal}(E/\mathbb{Q})$-actions.

**Proposition 2.8.** There is an isomorphism

$$
\Lambda_p(E)/p^m \Lambda_p(E) \simeq \text{im}(\text{AJ}_{E,m})
$$

of finite $O_p/p^mO_p$-modules.

**Proof.** Taking continuous cohomology of the short exact sequence of Galois modules

$$
0 \longrightarrow A_p \xrightarrow{p^m} A_p \longrightarrow A_p/p^m A_p \longrightarrow 0,
$$

where the second arrow is the multiplication-by-$p^m$ map and the third arrow is the canonical projection, and using the identification $W_p[p^m] = A_p/p^m A_p$, yields an injection

$$
i : H^1_{\text{cont}}(E, A_p) \otimes_{O_p}(O_p/p^mO_p) \hookrightarrow H^1(E, W_p[p^m])
$$

of $O_p/p^mO_p$-modules. On the other hand, if $j : H^1_f(E, W_p[p^m]) \hookrightarrow H^1(E, W_p[p^m])$ denotes the natural inclusion then part (3) of Corollary 2.7 implies that $\text{AJ}_{E,m}$ factors through $j$, and therefore the diagram

$$
\begin{array}{ccc}
\text{CH}^{k/2}(\mathbb{A}_N^{-k-2}/E) \\ \Psi
\end{array}
\begin{array}{c}
\longrightarrow
\end{array}
\begin{array}{c}
H^1_{\text{cont}}(E, A_p) \otimes_{O_p}(O_p/p^mO_p)
\end{array}
\begin{array}{c}
\longrightarrow
\end{array}
\begin{array}{l}
H^1_f(E, W_p[p^m])
\end{array}
\begin{array}{c}
j
\end{array}
\begin{array}{c}
\longrightarrow
\end{array}
\begin{array}{c}
H^1(E, W_p[p^m])
\end{array}
$$

where $\Psi$ is the $O_p/p^mO_p$-linear extension of $\text{AJ}_E$, commutes. Thus $\text{im}(i \circ \Psi)$ is equal to $\text{im}(j \circ \text{AJ}_{E,m})$, and the injectivity of $i$ and $j$ shows that $\text{im}(\Psi) \simeq \text{im}(\text{AJ}_{E,m})$. On the other hand, $\text{im}(\Psi) = \Lambda_p(E)/p^m \Lambda_p(E)$, and we are done. \hfill \Box

In particular, Proposition 2.8 implies that there is an injection

$$
\Lambda_p(E)/p^m \Lambda_p(E) \hookrightarrow H^1_f(E, W_p[p^m])
$$

of finite $O_p/p^mO_p$-modules; this map is Galois-equivariant if $E$ is Galois over $\mathbb{Q}$.

**Remark 2.9.** By an abuse of notation, we will often adopt the same symbol to denote an element of $\Lambda_p(E)/p^m \Lambda_p(E)$ and its image in $H^1_f(E, W_p[p^m])$ via (15).

2.5. **Beilinson–Bloch conjecture.** Now we recall the Beilinson–Bloch conjecture in this setting. Let $E$ be a number field and let $L(f \otimes E, s)$ be the complex $L$-function of $f$ over $E$.

**Conjecture 2.10** (Beilinson–Bloch, [1], [11]). $\dim_{F_p}(X_p(E)) = \text{ord}_{s = \frac{1}{2}} L(f \otimes E, s)$.

For details, see [24, pp. 158–168]. For generalizations to $L$-functions of motives, see [12]. The main result of [55], combined with the Gross–Zagier type formula for higher weight modular forms due to Zhang ([49]), gives the following result in the direction of the Beilinson–Bloch conjecture.

**Theorem 2.11** (Nekovár–Zhang). Let $K$ be an imaginary quadratic field in which all the prime numbers dividing $N$ split. If $\text{ord}_{s = \frac{1}{2}} L(f \otimes K, s) = 1$ then $\dim_{F_p}(X_p(K)) = 1$.

See [49, §5.3] for other results on the Beilinson–Bloch conjecture, especially when the base field is $\mathbb{Q}$. 
3. Divisibility properties of Heegner cycles

After reviewing the basic properties of Heegner cycles and the formalism of Darmon–Kolyvagin derivatives, we construct Kolyvagin classes attached to Heegner cycles and study their properties. The main result of this section (Theorem 3.33) is a congruence relation satisfied by these cohomology classes.

Fix throughout this paper an imaginary quadratic field $K$ of discriminant $D$ in which all the primes dividing $N$ split (in other words, $K$ satisfies the so-called “Heegner hypothesis” relative to $N$). Denote by $\mathcal{O}_K$ the ring of integers of $K$ and by $h_K$ its class number. For the sake of simplicity, assume also that $\mathcal{O}_K^\times = \{\pm 1\}$, i.e., that $K \neq \mathbb{Q}(\sqrt{-1})$ and $K \neq \mathbb{Q}(\sqrt{-3})$. Finally, fix an embedding $\mathbb{C} \hookrightarrow \mathbb{C}$.

3.1. Heegner cycles. We review construction and basic properties of Heegner cycles on Kuga–Sato varieties. In doing this, we follow [35] and [37] closely (for Heegner-type cycles on more general varieties that are fibered over modular curves, see [9, Section 2]).

Fix an ideal $N \subset \mathcal{O}_K$ such that $\mathcal{O}_K/N \simeq \mathbb{Z}/N\mathbb{Z}$, which exists thanks to the Heegner hypothesis satisfied by $K$. For any integer $T \geq 1$ prime to $NDp$ let $\mathcal{O}_T := \mathbb{Z} + T\mathcal{O}_K$ be the order of $K$ of conductor $T$. Let $X_0(N)$ be the compact modular curve of level $\Gamma_0(N)$; the isogeny $\mathbb{C}/\mathcal{O}_T \to \mathbb{C}/(\mathcal{O}_T \cap N)^{-1}$ defines a Heegner point $x_T \in X_0(N)$ that, by the theory of complex multiplication, is rational over the ring class field $K_T$ of $K$ of conductor $T$ (in particular, $K_1$ is the Hilbert class field of $K$).

Write $\kappa : X_N \to X_0(N)$ for the map induced by the inclusion $\Gamma(N) \subset \Gamma_0(N)$ and choose $\tilde{x}_T \in \kappa^{-1}(x_T)$. The elliptic curve $E_T$ corresponding to $\tilde{x}_T$ has complex multiplication by $\mathcal{O}_T$. Fix the unique square root $\xi_T = \sqrt{-DT^2}$ of the discriminant of $\mathcal{O}_T$ with positive imaginary part under the chosen embedding of $K$ into $\mathbb{C}$. For any $a \in \mathcal{O}_T$ let $\Gamma_{T,a} \subset E_T \times E_T$ denote the graph of $a$ and let $i_{\tilde{x}_T} : \pi_{k-2}^{-1}(\tilde{x}_T) \to \tilde{E}_N^{k-2}$ be the canonical inclusion. Then
\begin{equation}
\Pi_B \Pi_i(i_{\tilde{x}_T})_* \left( \Gamma_{T,\xi_T}^{(k-2)/2} \right) \in \Pi_B \Pi_i \left( CH^{k/2}(\tilde{E}_N/K_T) \otimes \mathbb{Z}_p \right)
\end{equation}
and we define the Heegner cycle
\[ y_{T,p} \in H^1_{cont}(K_T, A_p) \]
to be the image of the cycle in (16) via the map $\Psi_{f,p,K_T}$ introduced in [8]. This class is independent of the choice of $\tilde{x}_T$ ([35] p. 107) and, by [37] Ch. II, §3.6, does not change if $\Gamma_{T,\xi_T}$ is replaced by $\Gamma_{T,\xi_T} \setminus \{(E_T \times \{0\}) \cup \{0\} \times E_T\}$ in (16), which is the choice made in [35] §5. Finally, note that
\[ y_{T,p} \in \Lambda_p(K_T) \]
because the Abel–Jacobi map $AJ_{K_T}$ factors through $\Psi_{f,p,K_T}$.

Define
\begin{equation}
S := \{ \ell \text{ prime number } | \ell \text{ is inert in } K \text{ and } \ell \nmid Np \}.
\end{equation}
For each $\ell \in S$ the extension $K_{cT}/K_1$ is cyclic of order $\ell +1$ and unramified at primes different from $\ell$. Also, if $\ell \neq \ell'$ are in $S$ then $K_{cT}$ and $K_{cT'}$ are linearly disjoint over $K_1$. Fix a product $T = \prod_{i=1}^l \ell_i$ of distinct primes $\ell_i \in S$, then put $G_T := Gal(K_{cT}/K_1)$ and $\Gamma_T := Gal(K_{cT}/K)$. The field $K_T$ is the composite of the fields $K_{\ell_i}$, which are linearly disjoint over $K_1$, and so there is a decomposition $G_T = \prod_{i=1}^l G_{\ell_i}$. In particular, if $T' | T$ then there is a canonical inclusion $G_{T'} \subset G_T$, using which we identify the elements of $G_{T'}$ with their images in $G_T$. Finally, set $\Gamma_1 := Gal(K_1/K)$, so that $\Gamma_1 \simeq Pic(\mathcal{O}_K)$ and $|\Gamma_1| = h_K$.

Let us recall two basic properties of Heegner cycles, which extend those of Heegner points and are due to Nekovár ([35]). Before stating them, we fix some notations that will be used in the rest of the paper.
Choose a complex conjugation \( c \in G_{\Q} \) and use the same symbol to denote the images of \( c \) in quotients of \( G_{\Q} \); in other words, \( c \) is a lift to \( G_{\Q} \) of the generator of \( \Gal(K/\Q) \). We shall also write \( \Frob_{\infty} \) for the conjugacy class of \( c \) in \( \Gal(E/\Q) \), relying on the context to make clear which number field \( E \) we are considering. Finally, recall that \( \cores_{K_T/\Q} \) denotes the corestriction map from \( H^1(K_{T_\ell}, A_p) \) to \( H^1(K_T, A_p) \) and let \( \epsilon \) be the sign of the functional equation of \( L(f, s) \).

**Proposition 3.1.** Let \( T \) be a square-free product of primes in \( S \).

1. If \( \ell \in S, \ell \nmid T \) then \( \cores_{K_T/\Q}(y_{T,\ell}, p) = (a_{\ell}/\ell^{k/2-1}) \cdot y_{T,\ell} \).
2. There exists \( \sigma \in \Gamma_T \) such that \( c(y_{T,\ell}) = -\epsilon \cdot \sigma(y_{T,\ell}) \).

**Proof.** Upon applying the projection \( A_p \to A_p \), part (1) is [35 Proposition 6.1, (1)], while part (2) is [35 Proposition 6.2]. (Note the misprint in loc. cit., since the Hecke action is twisted by \( k/2 - 1 \)).

**Remark 3.2.** The relations stated in Proposition 3.1 together with the Key Formula appearing in [35 §9] (that will be used in the proof of Proposition 3.19 below), describe an Euler system for modular forms of weight \( k > 2 \). Euler systems for higher weight modular forms can also be constructed by using Howard’s work [23] on the variation of Heegner points in Hida families, later extended to the case of indefinite Shimura curves in [21] and [30], by specialization to weight \( k \). The relation between the two systems has been investigated by Castella in [16], and we expect that a similar approach could be adopted in the case of indefinite Shimura curves as well. We finally remark that, in yet another direction, it would be interesting to generalize to higher weight the Euler systems of Heegner points introduced by means of congruences between modular forms in [8] and developed in [25], [26], [27], [28], [29], [10]. In connection with this, see work in progress by Chida and Hsieh ([17]).

**3.2. \( \pm \)-eigenspaces.** Recall that if \( M \) is an abelian group endowed with an action of an involution \( \tau \) and 2 is invertible in \( \End(M) \) then there is a decomposition \( M = M^+ \oplus M^- \) where \( M^\pm \) is the subgroup of \( M \) on which \( \tau \) acts as \( \pm 1 \).

Let \( p \) be a prime number as in the introduction and let \( \mathfrak{p} \) a prime ideal of \( \mathcal{O}_F \) above \( p \). Since \( \Gal(K/\Q) \) acts on \( X_p(K) \), the above formalism applies and there is a decomposition

\[
X_p(K) = X_p(K)^+ \oplus X_p(K)^-.
\]

Define \( \rho_p^\pm := \dim_{F_p}(X_p(K)^\pm) \) and

\[
\rho_p := \begin{cases} 
\max\{\rho_p^+, \rho_p^-\} - 1 & \text{if } \rho_p^+ \neq \rho_p^-; \\
\rho_p^+ & \text{otherwise.}
\end{cases}
\]

(18)

Two remarks on these definitions, both related with the Beilinson–Bloch conjecture, are now in order.

**Remark 3.3.** 1) Conjecture [2,10] predicts, among other things, that the \( F_p \)-dimension of \( X_p(E) \) does not depend on \( \mathfrak{p} \), and therefore \( \rho_p^+ + \rho_p^- \) is conjecturally independent of \( \mathfrak{p} \). Moreover, let \( f \otimes \epsilon_K \) be the twist of \( f \) by the quadratic Dirichlet character \( \epsilon_K \) attached to the extension \( K/\Q \). It can be shown (see [31 §6.1] for details; in [31] a \( p \)-ordinarity assumption is made, but this condition plays no role in the results about Selmer groups that we are interested in) that

\[
X_p(K)^+ \simeq X_p(\Q) = \im(\Psi_{f,\Q}) \otimes_{\mathcal{O}_p} F_p, \quad X_p(K)^- \simeq \im(\Psi_{f \otimes \epsilon_K, \Q}) \otimes_{\mathcal{O}_p} F_p.
\]

Therefore Conjecture [2,10] (for \( f \) and \( E = \Q \) or \( f \otimes \epsilon_K \) and \( E = \Q \)) implies that \( \rho_p^+ \) and \( \rho_p^- \) do not depend on \( p \).
2) As before, let $L(f \otimes K,s)$ denote the $L$-function of $f$ over $K$, so that
\begin{equation}
L(f \otimes K,s) = L(f,s) \cdot L(f \otimes \epsilon_K,s).
\end{equation}
Since the orders of vanishing of $L(f,s)$ and $L(f \otimes \epsilon_K,s)$ at $s = k/2$ have opposite parities (cf., e.g., [13, p. 543]), it follows from (19) that $L(f \otimes K,s)$ vanishes to odd order at $s = k/2$. Therefore Conjecture 2.10 predicts that the $F_p$-dimension $\rho_p^+ + \rho_p^-$ of $X_p(K)$ should be odd, hence we expect the second possibility in [18] not to occur.

3.3. Rank inequalities. As a consequence of the structure theorem for finitely generated modules over principal ideal domains, a finite $\mathcal{O}_p/p^m\mathcal{O}_p$-module $M$ can be decomposed as
\begin{equation}
M \simeq (\mathcal{O}_p/p^m\mathcal{O}_p)^{r_{p,m}(M)} \oplus \tilde{M}
\end{equation}
where the exponent of $\tilde{M}$ divides $p^m$ strictly and the integer $r_{p,m}(M)$ does not depend on such a decomposition (see Lemma 3.4 below).

Let $\mathbb{F}_p := \mathcal{O}_p/p\mathcal{O}_p$ be the residue field of $\mathcal{O}_p$. In the sequel we will make use of the following auxiliary result.

Lemma 3.4. Let $M, M', M''$ be finite $\mathcal{O}_p/p^m\mathcal{O}_p$-modules.

1) If there is an injective homomorphism $M \hookrightarrow M'$ then $r_{p,m}(M) \leq r_{p,m}(M')$.

2) If there is a surjective homomorphism $M \rightarrow M'$ then $r_{p,m}(M) \geq r_{p,m}(M')$.

3) If there is an exact sequence of $\mathcal{O}_p/p^m\mathcal{O}_p$-modules
\begin{equation}
0 \rightarrow M' \rightarrow M \rightarrow M''
\end{equation}
then
\begin{equation}
r_{p,m}(M) \leq r_{p,m}(M') + \dim_{\mathbb{F}_p}(M'' \otimes_{\mathcal{O}_p/p^m\mathcal{O}_p} \mathbb{F}_p).
\end{equation}

Proof. An injection $M \hookrightarrow M'$ of $\mathcal{O}_p/p^m\mathcal{O}_p$-modules induces an injection $p^{m-1}M \hookrightarrow p^{m-1}M'$ of $\mathbb{F}_p$-vector spaces, hence
\begin{equation}
r_{p,m}(M) = \dim_{\mathbb{F}_p}(p^{m-1}M) \leq \dim_{\mathbb{F}_p}(p^{m-1}M') = r_{p,m}(M'),
\end{equation}
which shows part (1). On the other hand, a surjection $M \twoheadrightarrow M'$ of $\mathcal{O}_p/p^m\mathcal{O}_p$-modules induces a surjection $p^{m-1}M \twoheadrightarrow p^{m-1}M'$ of $\mathbb{F}_p$-vector spaces, and part (2) follows similarly. Finally, part (3) can be proved as [18] Lemma 5.1. \hfill \square

As before, let $K$ be our imaginary quadratic field where all the prime factors of $N$ split.

With notation as in (20), set
\begin{equation}
\tilde{r}_{p,m} := r_{p,m}(H^1_f(K,W_p[p^m])).
\end{equation}
Moreover, recall the integers $\rho_p^\pm$ introduced in [3,2] and define
\begin{equation}
\tilde{\rho}_p := \rho_p^+ + \rho_p^- = \dim_{\mathbb{F}_p}(X_p(K)).
\end{equation}
Observe that there is an obvious inequality
\begin{equation}
\tilde{\rho}_p \leq r_{p,m}(\Lambda_p(K)/p^m\Lambda_p(K)).
\end{equation}

Proposition 3.5. $\tilde{\rho}_p \leq \tilde{r}_{p,m}$.

Proof. It follows from Proposition 2.8 and Lemma 3.4 that
\begin{equation}
r_{p,m}(\Lambda_p(K)/p^m\Lambda_p(K)) = r_{p,m}(\text{im}(\Lambda_J_{K,m})) \leq r_{p,m}(H^1_f(K,W_p[p^m])) = \tilde{r}_{p,m}.
\end{equation}
Combining (22) and (23) gives the desired inequality. \hfill \square
Since $p$ is odd, there is a splitting
\[ H_f^1(K, W_p[p^m]) = H_f^1(K, W_p[p^m])^+ \oplus H_f^1(K, W_p[p^m])^- \]
under the action of complex conjugation $c \in \text{Gal}(K/\Q)$. Set
\[ \tilde{r}_{p,m}^\pm := r_{p,m}(H_f^1(K, W_p[p^m])^\pm) \]
and define
\[ r_{p,m} := \begin{cases} \max \{ \tilde{r}_{p,m}^+, \tilde{r}_{p,m}^- \} - 1 & \text{if } \tilde{r}_{p,m}^+ \neq \tilde{r}_{p,m}^-, \\ \tilde{r}_{p,m}^+ & \text{otherwise.} \end{cases} \]
Recall the integer $\rho_p$ defined in [IS].

Proposition 3.6. $\rho_p \leq r_{p,m}$.

Proof. Combine the $\text{Gal}(K/\Q)$-equivariance of the Abel–Jacobi map with Proposition 3.5. \( \square \)

3.4. Darmon–Kolyvagin derivatives. In this subsection we consider the general formalism of Darmon–Kolyvagin derivatives in the case of ring class fields of square-free conductor.

Fix a square-free product $S = \prod_{i=1}^{t} \ell_i$ of primes $\ell_i$ in $\calo_{p,m}$. For a prime $\ell | S$ let $\sigma_\ell$ be a generator of $G_\ell$. For any integer $k$ such that $0 \leq k \leq \ell = \#G_\ell - 1$ define the derivative operator
\[ D_\ell^k := \sum_{i=k}^{\ell} \binom{i}{k} \sigma_\ell^i \in \Z[G_\ell] \subset \calo_p[G_\ell]. \]
If $\kappa = (k_1, \ldots, k_t) \in \Z^t$ with $0 \leq k_i \leq \ell_i$ then the Darmon–Kolyvagin $\kappa$-derivative is
\[ D_\kappa := D_{\ell_1}^{k_1} \cdots D_{\ell_t}^{k_t} \in \Z[G_S] \subset \calo_p[G_S]. \]
The order, the support and the conductor of $D_\kappa$ are defined as
\[ \text{ord}(D_\kappa) := \sum_{i=1}^{t} k_i, \quad \text{supp}(D_\kappa) := S, \quad \text{cond}(D_\kappa) := \prod_{k_i > 0} \ell_i, \]
respectively, and we set
\[ \eta(\kappa) := \min \{ \text{ord}_p(n_i) \mid k_i > 0 \}. \]
Finally, given $\kappa = (k_1, \ldots, k_s)$ and $\kappa' = (k'_1, \ldots, k'_s)$ we say that $D_\kappa'$ is less than $D_\kappa$ if $k'_i \leq k_i$ for all $i$, and we write $\kappa' \leq \kappa$ in this case. Moreover, we say that $D_\kappa'$ is strictly less than $D_\kappa$, written $\kappa' < \kappa$, if $\kappa' \leq \kappa$ and $\kappa' \neq \kappa$.

Now we collect some basic facts about these derivatives. Most of them will not be used until Section 4 but we prefer to gather them here for the sake of clarity. The proofs are straightforward computations and will be omitted: see [IS] §3.1 and §4.1 for details.

3.4.1. Taylor’s formula. The resolvent element associated with an element $m$ of an $\calo_p[G_S]$-module $M$ is defined as
\[ \theta_m := \sum_{\sigma \in G_S} \sigma(m) \otimes \sigma \in M \otimes \calo_p \calo_p[G_S]. \]
Then
\[ \theta_m = \sum_{\kappa} D_\kappa(m) \otimes (\sigma_1 - 1)^{k_1} \cdots (\sigma_t - 1)^{k_t}, \]
where the sum is taken over all $t$-tuples of integers $\kappa = (k_1, \ldots, k_t)$, with the convention that only those $\kappa$ with $0 \leq k_i \leq \ell_i$ for all $i$ appear in the above sum.

3.4.2. Divisibility criterion. Let $I_{G_S}$ be the augmentation ideal of $\calo_p[G_S]$ and let $r \leq p$ be an integer. If $D_\kappa(m) \equiv 0 \pmod{p^{\eta(\kappa)}}$ for all $\kappa$ with $\text{ord}(\kappa) < r$ then $\theta_m$ belongs to the natural image of $M \otimes \calo_p I_{G_S}$. 
3.4.3. **Action of complex conjugation.** The action of \( c \in \text{Gal}(K/\mathbb{Q}) \) on \( \Gamma_S = \text{Gal}(K_S/K) \) by conjugation sends \( \sigma \) to \( \sigma^{-1} \). This induces an action of \( c \) on \( \mathcal{O}_p[G_S] \) by linearity, and the formula

\[
c D_\kappa c^{-1} = (-1)^{\text{ord}(c)}D_\kappa + \sum_{\kappa' < \kappa} \alpha_{\kappa'}D_{\kappa'}
\]

holds for suitable integers \( \alpha_{\kappa'} \).

3.4.4. **Some formulas.** For any prime \( \ell \mid S \) and any integer \( k \) with \( 0 \leq k \leq \ell \) we have

\[
(\sigma_\ell - 1)D_\ell^k = \binom{\ell + 1}{k} - \sigma_\ell D_\ell^{k-1}.
\]

In particular, since \( p^m \mid \ell + 1 \), for all \( 0 < k < p \) we have

\[
(\sigma_\ell - 1)D_\ell^k \equiv -\sigma_\ell D_\ell^{k-1} \pmod{p^m}.
\]

3.4.5. **Special bases.** An element \( \xi \in \mathbb{Z}[G_\ell] \), for a prime \( \ell \mid S \), can be written as a \( \mathbb{Z} \)-linear combination of the derivatives \( D_\ell^k \) for \( k = 0, \ldots, \ell \). Since this is not justified in [18], we give a short proof. Write \( \xi = \sum_{i=0}^\ell a_i \sigma_i \). By rearranging the sums, one can check that a linear combination \( \sum_{k=0}^\ell a_k D_\ell^k \) of derivatives can be written as \( \sum_{i=0}^\ell \left( \sum_{k=0}^i a_k \binom{i}{k} \right) \sigma_i \). Therefore we have to prove that we can find coefficients \( a_k \in \mathbb{Z} \) such that \( \sum_{k=0}^i a_k \binom{i}{k} = a_i \) for all \( i = 0, \ldots, \ell \). The generic equation in this system is

\[
a_0 + ia_1 + \binom{i}{2} a_2 + \cdots + \binom{i}{i-1} a_{i-1} + a_i = a_i,
\]

and the desired solution can be found recursively.

3.5. **The set of exceptional primes.** The main result of this section, Theorem 3.33, applies to all primes \( p \) outside a finite set \( \Sigma \) that we describe below.

Let \( \Sigma \) be the set of prime numbers \( p \) satisfying at least one of the following conditions:

- \( p \mid 6N\text{D}(k-2)!\phi(N) \) and \( p \) ramifies in \( F \);
- the image of the \( p \)-adic representation

\[
\rho_{f,p} : G_\mathbb{Q} \longrightarrow \text{GL}_2(\mathcal{O}_F \otimes \mathbb{Z}_p)
\]

attached to \( f \) by Deligne ([19]) does not contain the set

\[
\{ g \in \text{GL}_2(\mathcal{O}_F \otimes \mathbb{Z}_p) \mid \det(g) \in (\mathbb{Z}_p^\times)^{k-1} \}.
\]

To begin with, we need the following

**Lemma 3.7.** **The set \( \Sigma \) is finite.**

**Proof.** The only non-trivial fact to check is that there are only finitely many prime numbers satisfying the last condition, and this follows from [22, Theorem 3.1]. \( \square \)

For a prime number \( p \not\in \Sigma \) and an integer \( m \geq 1 \) define

\[
S_{p^m} := \{ \ell \text{ prime number } \mid \ell \text{ is inert in } K, \ell \nmid N \text{ and } p^m \mid \ell + 1 \}.
\]

Notice that \( S_{p^m} \subset S \) with \( S \) defined in (17). As a piece of notation, when we write that a prime ideal of \( \mathbb{Z} \) belongs to a set \( \Theta \) of prime numbers we mean that the positive generator of this ideal belongs to \( \Theta \). Let \( \mu_{p^m} \) denote the \( p^m \)-th roots of unity in \( \mathbb{Q} \). By [18 Lemma 3.14], a prime \( \ell \) belongs to \( S_{p^m} \) precisely when \( \text{Frob}_\ell = \text{Frob}_{p^m} \in \text{Gal}(K(\mu_{p^m})/K) \), hence \( S_{p^m} \) is infinite by Chebotarev's density theorem. Furthermore, there is an inclusion \( \mu_{p^m} \subset K_\lambda \) for every prime \( \lambda \) of \( K \) such that \( \lambda \cap \mathbb{Z} \in S_{p^m} \).

With \( \Sigma \) as above, fix from now to the end of this section a prime number \( p \not\in \Sigma \) and a quadruplet \( (p^m, S, D_\kappa, \ell) \) consisting of
3.6. Kolyvagin classes attached to Heegner cycles. In this subsection we introduce classes $d(E) \in H^1(K, W_p[p^m])$ depending on the data $S$, $p^m$, $D_\nu$ and $\ell$.

Let

$$\vartheta_p : G_\mathcal{P} \to \text{Aut}(A_p)$$

be the Galois representation attached to $A_p$. For every integer $m \geq 1$ the group $G_\mathcal{P}$ acts on $W_p[p^m]$ via its action on $A_p$, and we obtain a representation

$$\vartheta_{p,m} : G_\mathcal{P} \to \text{Aut}(W_p[p^m]).$$

In particular, $\vartheta_p := \vartheta_{p,1}$ is a residual representation of $G_\mathcal{P}$ over the finite field $\mathbb{F}_p$.

For any subfield $L$ of $\bar{\mathbb{Q}}$ write $A_p(L)$ and $W_p[p^m](L)$ for $R^0\text{Cont}(L, A_p)$ and $H^0(L, W_p[p^m])$, respectively; similar conventions apply when $L$ is a completion of a number field.

Lemma 3.8. If $p \cap \mathbb{Z} \notin \Sigma$ then $\vartheta_p$ and $\vartheta_p$ are irreducible and have non-solvable images.

Proof. By [10, Lemma 6.2], the image of $\vartheta_p$ in $\text{Aut}(A_p) \simeq \text{GL}_2(\mathcal{O}_p)$ contains a subgroup that is conjugate to $\text{GL}_2(\mathbb{Z}_p)$. Since $p \neq 2$, this implies the irreducibility of $\vartheta_p$ and $\vartheta_p$ (see [10, Proposition 6.3, (1)] for details). Finally, the groups $\text{GL}_2(\mathbb{Z}_p)$ and $\text{GL}_2(\mathbb{F}_p)$ are not solvable because $p > 3$, hence the images of $\vartheta_p$ and $\vartheta_p$ are not solvable.

Lemma 3.9. If $p \cap \mathbb{Z} \notin \Sigma$ and the extension $E/\mathbb{Q}$ is solvable then

1. $A_p(E) = 0$;
2. $W_p[p^m](E) = 0$ for all $n \geq 1$.

Proof. Let us prove part (1). Since $p \cap \mathbb{Z} \notin \Sigma$, Lemma 3.8 ensures that $\vartheta_p$ is irreducible with non-solvable image. The submodule $A_p(E)$ of $A_p$ is $G_{\mathcal{P}}$-stable, hence if $A_p(E) \neq 0$ then $A_p(E) = A_p$ by the irreducibility of $\vartheta_p$. Thus $\vartheta_p$ factors through $\text{Gal}(E/\mathbb{Q})$, which is solvable by assumption. It follows that $\text{im}(\vartheta_p)$ is solvable, which is a contradiction. Finally, in order to prove part (2) it is of course enough to prove the claim for $n = 1$, and this can be done mutatis mutandis in the same way, using again Lemma 3.8.

Write $L_m := K(W_p[p^m])$ for the composite of $K$ and the subfield of $\bar{\mathbb{Q}}$ fixed by $\ker(\vartheta_{p,m})$. With notation as in [5.1] define a set $\mathcal{S}_{p^m}$ of prime numbers as

$$\mathcal{S}_{p^m} := \{ \ell \text{ prime number} \mid \ell \nmid NDp \text{ and } \text{Frob}_\ell = \text{Frob}_\infty \text{ in } \text{Gal}(L_m/\mathbb{Q}) \}.$$  

Again by Čebotarev’s density theorem, $\mathcal{S}_{p^m}$ is infinite.

Lemma 3.10. A prime $\ell$ not dividing $D$ belongs to $\mathcal{S}_{p^m}$ if and only if $\ell$ belongs to $\mathcal{S}_{p^m}$ and $p^m$ divides $a_\ell$ in $\mathcal{O}_F$.

Proof. Equating the minimal polynomials of $F_{\ell}$ (see [2]) and of $c$ acting on $W_p[p^m]$, one finds the divisibility relations $p^m | a_\ell$ and $p^m | \ell + 1$ in $\mathcal{O}_F$. Since $p$ is unramified in $F$, the second relation gives an inclusion $(\ell + 1) \subset (p^m)$ of principal ideals of $\mathcal{O}_F$; this immediately implies that $p^m | \ell + 1$ in $\mathbb{Z}$, which concludes the proof.

With notation as before, let $\ell \in \mathcal{S}_{p^m}$ and put $T := S\ell$. Define

$$\tilde{P}(\ell) := D_pD_\ell^1(y_{T,p}) \in \Lambda_p(K_T),$$

then denote by

$$P(\ell) \in \Lambda_p(K_T)/p^m \Lambda_p(K_T)$$
the image of \( \tilde{P}(\ell) \) under the canonical projection.

With the exception of \([6.8]\) from here till the end of \([8.3]\) we will work under the following technical assumption on \((p^m, S, D_\kappa, \ell)\).

**Assumption 3.11.** For all \(D_{\kappa'}\) strictly less than \(D_\kappa D_1^1\) we have \(D_{\kappa'}(y_{T,p}) = 0\).

With this condition in force, we can prove

**Lemma 3.12.** The class \(P(\ell)\) is fixed by the action of \(G_T\).

*Proof.* Let \(\sigma = \sigma_\ell\) or \(\sigma = \sigma_\ell\). Congruence \([22]\) shows that
\[
(\sigma - 1)\tilde{P}(\ell) \equiv -\sigma D_{\kappa'}(y_{T,p}) \pmod{p^m}
\]
for some \(D_{\kappa'}\) strictly less than \(D_\kappa D_1^1\), which concludes the proof. \(\square\)

Recall from \([15]\) that there is an injective, Galois-equivariant map of \(\mathcal{O}_p/p^m\mathcal{O}_p\)-modules
\[
\Lambda_p(K_T)/p^m \Lambda_p(K_T) \hookrightarrow H^1(K_T, W_p[p^m]) \subset H^1(K_T, W_p[p^m]).
\]

By Lemma 3.12 the image of \(P(\ell)\) via this map belongs to \(H^1(K_T, W_p[p^m])^{G_T}\), hence to \(H^1(K_T, W_p[p^m])^{G_T}\). Since \(K_T/Q\), being generalized dihedral, is solvable, part (2) of Lemma 3.9 and the inflation-restriction exact sequence give an isomorphism
\[
\res_{K_T/K_1} : H^1(K_1, W_p[p^m]) \xrightarrow{\cong} H^1(K_T, W_p[p^m])^{G_T}.
\]

Let \(N = N_{K_1/K} := \sum_{\sigma \in \Gamma_1} \sigma \in \mathbb{Z}[\Gamma_1]\) denote the norm operator from \(K_1\) to \(K\). The abelian group \(H^1(K_1, W_p[p^m])\) is naturally a \(\Gamma_1\)-module, so \(N\) induces a map
\[
N : H^1(K_1, W_p[p^m]) \longrightarrow H^1(K_1, W_p[p^m])^{\Gamma_1}.
\]

Since \(p \nmid h_K\), inflation-restriction shows that there is an isomorphism
\[
\res_{K_1/K} : H^1(K_1, W_p[p^m]) \xrightarrow{\cong} H^1(K_1, W_p[p^m])^{\Gamma_1}.
\]

Consider the diagram
\[
\begin{array}{ccc}
H^1(K_1, W_p[p^m]) & \xrightarrow{\res_{K_T/K_1}^{-1}} & H^1(K_T, W_p[p^m])^{G_T} \\
\downarrow N & & \downarrow \beta \\
H^1(K_1, W_p[p^m])^{\Gamma_1} & \xrightarrow{\res_{K_1/K}^{-1}} & H^1(K, W_p[p^m])
\end{array}
\]

where the dotted arrow \(\beta\) is defined so as to make the resulting square commute. Thus we can attach to \(P(\ell) \in H^1(K_T, W_p[p^m])^{G_T}\) a Kolyvagin class
\[
d(\ell) := \beta(P(\ell)) \in H^1(K, W_p[p^m])
\]
such that
\[
(26) \quad \res_{K_T/K}(d(\ell)) = N_T(P(\ell))
\]
where \(N_T \in \mathbb{Z}[\Gamma_T]\) is an arbitrary lift of \(N\) via the canonical projection \(\Gamma_T \rightarrow \Gamma_1\) (if \(N'_{T}\) is another such lift then \(N_T(P(\ell)) = N'_{T}(P(\ell))\) by Lemma 3.12). Furthermore, since \(\res_{K_T/K}\) is an isomorphism, \(d(\ell)\) is the only class in \(H^1(K, W_p[p^m])\) satisfying \((26)\).
3.7. Action of complex conjugation on Kolyvagin classes. Recall that $\varepsilon$ is the sign of the functional equation of $L(f, s)$ and set $\varepsilon_\kappa := (-1)^{\text{ord}(D_\kappa)} \varepsilon$.

Proposition 3.13. The class $d(\ell)$ belongs to the $\varepsilon_\kappa$-eigenspace of $H^1(K, W_p[p^m])$ under the action of $\varepsilon$.

Proof. By (3.4.3) and Assumption 3.11 there is an equality

$$c(\bar{P}(\ell)) = (-1)^{\text{ord}(D_\kappa)} D_\kappa D_\ell c(y_{T, p}).$$

Since the ring $\mathbb{Z}[\Gamma_T]$ is commutative, part (2) of Proposition 3.11 then shows that

$$c(P(\ell)) = -(-1)^{\text{ord}(D_\kappa)} D_\kappa D_\ell c(P(\ell))$$

for a suitable $\sigma \in \Gamma_T$. Applying any lift $N_T = \sum_{i=1}^h \sigma_i \in \mathbb{Z}[\Gamma_T]$ of $N$ on both sides gives

$$N_T(c(P(\ell))) = -(-1)^{\text{ord}(D_\kappa)} D_\kappa D_\ell N_T(\sigma(P(\ell))).$$

Now $\sum_{i=1}^h \sigma_i c = c \sum_{i=1}^h \sigma_i^{-1}$. Moreover, since $N_T' := \sum_{i=1}^h \sigma_i^{-1}$ and $N_T'' := \sum_{i=1}^h \sigma_i \sigma$ are two lifts of $N$, equality (26) implies that

$$N_T'(P(\ell)) = \text{res}_{K_T/K}(d(\ell)) = N_T''(P(\ell)).$$

By definition of $\varepsilon_\kappa$, combining (27) and (28) gives

$$c \cdot \text{res}_{K_T/K}(d(\ell)) = \varepsilon_\kappa \text{res}_{K_T/K}(d(\ell)),$$

and the conclusion follows from the Gal($K/Q$)-equivariance of the isomorphism res$_{K_T/K}$. □

3.8. Tate duality. In this subsection we do not suppose that Assumption 3.11 holds. Let $\lambda$ denote the unique prime of $K$ above $\ell$. By [35, Proposition 3.1, (2)], there is a $G_Q$-equivariant skew-symmetric pairing

$$[\cdot, \cdot]: A_p \times A_p \rightarrow \mathbb{Z}_p(1)$$

such that the induced pairing

$$[\cdot, \cdot]_m : W_p[p^m] \times W_p[p^m] \rightarrow \mu_{p^m}$$

is non-degenerate. With notation as before, combining cup product in cohomology with the map $W_p[p^m] \otimes W_p[p^m] \rightarrow \mu_{p^m}$ induced by $[\cdot, \cdot]_m$ gives rise to a pairing

$$\langle \cdot, \cdot \rangle : H^1(K_\lambda, W_p[p^m]) \times H^1(K_\lambda, W_p[p^m]) \rightarrow H^2(K_\lambda, \mu_{p^m}) = \mathbb{Z}/p^m\mathbb{Z},$$

with the equality on the right coming from the invariant map of local class field theory. By a result of Tate, this pairing is non-degenerate (cf. [34, Ch. I, Corollary 2.3]).

Since $A_p$ is unramified at $\lambda$, the group $H^1(K_\lambda, W_p[p^m]) = H^1_{\text{ur}}(K_\lambda, W_p[p^m])$ is its own annihilator in $H^1(K_\lambda, W_p[p^m])$ under Tate’s pairing $\langle \cdot, \cdot \rangle$ ([10, Lemma 4.4]). The singular part of the cohomology is then defined via the short exact sequence

$$0 \rightarrow H^1(K_\lambda, W_p[p^m]) \rightarrow H^1(K_\lambda, W_p[p^m]) \rightarrow H^1_{\text{sin}}(K_\lambda, W_p[p^m]) \rightarrow 0,$$

and $\langle \cdot, \cdot \rangle$ induces a Gal($K/Q$)-equivariant perfect pairing

$$\langle \cdot, \cdot \rangle : H^1_{\text{sin}}(K_\lambda, W_p[p^m]) \times H^1_{\text{sin}}(K_\lambda, W_p[p^m]) \rightarrow \mathbb{Z}/p^m\mathbb{Z}.$$

It follows that there are natural identifications

$$H^1_{\text{sin}}(K_\lambda, W_p[p^m]) = \text{Hom}_{\text{cont}}(\text{Gal}(K_\lambda/K_\lambda^\text{ur}), W_p[p^m])$$

where $K_\lambda^\text{ur}$ is the maximal unramified extension of $K_\lambda$. Let $K_\lambda^\text{t}$ denote the maximal tamely ramified extension of $K_\lambda$. The wild inertia group $\text{Gal}(K_\lambda/K_\lambda^\text{t})$ is a pro-$\ell$-group and $\ell \neq p$, hence equalities (30) yield a further identification

$$H^1_{\text{sin}}(K_\lambda, W_p[p^m]) = \text{Hom}_{\text{cont}}(\text{Gal}(K_\lambda/K_\lambda^\text{t}), W_p[p^m]).$$
Fix a (topological) generator $\tau$ of $\text{Gal}(K_1^w/K_0^w)$, so that $\tau$ and a lift to $\text{Gal}(K_1^w/K_0^w)$ of the Frobenius $F_\ell \in \text{Gal}(K_0^w/K_0)$ generate $\text{Gal}(K_1^w/K_0^w)$ topologically. In light of (31), evaluating homomorphisms at $\tau$ gives an isomorphism

$$\alpha_\lambda : H^1_{\text{sin}}(K_\lambda, W_p[p^m]) \xrightarrow{\sim} W_p[p^m].$$

On the other hand, by [10, Lemma 6.8], if $\ell \in \mathcal{S}_p^w$ then evaluation at $\text{Frob}_\lambda$ gives a $\text{Gal}(K/Q)$-equivariant isomorphism

$$\beta_\lambda : H^1_f(K_\lambda, W_p[p^m]) \xrightarrow{\sim} W_p[p^m].$$

It follows that for every $\ell \in \mathcal{S}_p^w$ there is an isomorphism

$$\nu_\lambda := \alpha_\lambda^{-1} \circ \beta_\lambda : H^1_f(K_\lambda, W_p[p^m]) \xrightarrow{\sim} H^1_{\text{sin}}(K_\lambda, W_p[p^m])$$

of $\mathcal{O}_p/p^m\mathcal{O}_p$-modules.

As a piece of notation, for a $\mathbb{Z}/p^m\mathbb{Z}$-module $M$ write

$$M^* := \text{Hom}(M, \mathbb{Z}/p^m\mathbb{Z})$$

for the Pontryagin dual of $M$. Note that if $M$ is endowed with a $\mathbb{Z}/p^m\mathbb{Z}$-linear action of an involution $\tau$ then $M^*$ inherits a $\mathbb{Z}/p^m\mathbb{Z}$-linear action of $\tau$ by setting

$$(\tau \cdot f)(m) := f(\tau \cdot m)$$

for all $f \in M^*$ and all $m \in M$. Letting the superscripts $\pm$ denote the $\pm$-eigenspaces under the actions of $\tau$, there are canonical isomorphisms

$$\nu_\lambda^* \xrightarrow{\sim} \nu_\lambda$$

of $\mathbb{Z}/p^m\mathbb{Z}$-modules.

With this notation in force, the pairing in (29) is equivalent to an isomorphism

$$(M^*)^\pm \xrightarrow{\sim} (M^\pm)^*$$

of $\mathbb{Z}/p^m\mathbb{Z}$-modules.

3.9. Local behaviour of Kolyvagin classes. By class field theory, $\lambda$ splits completely in $K_S/K$; choose a prime $\lambda_S$ of $K_S$ above $\lambda$. Furthermore, $\lambda_S$ is totally ramified in $K_T/K_S$; write $\lambda_T$ for the unique prime of $K_T$ above it.

As before, if $v$ is a place of $K$ then write $K_v$ for the completion of $K$ at $v$. There is a localization (restriction) map

$$\text{res}_v : H^1(K, W_p[p^m]) \longrightarrow H^1(K, W_p[p^m])$$

and if $s \in H^1(K, W_p[p^m])$ then we write $s_v$ for $\text{res}_v(s)$.

Proposition 3.15. If $v$ is an archimedean place of $K$ then $d(\ell)_v = 0$.

Proof. The quadratic field $K$ is imaginary, hence $K_v = \mathbb{C}$. The proposition follows because $\mathbb{C}$ is algebraically closed and so $H^1(\mathbb{C}, W_p[p^m]) = 0$. □

Now set $S' := \text{cond}(D_e)$. 

Remark 3.14. In light of the perfect pairing (29), when dealing with Tate’s duality we shall often use the same symbol to denote $d(\ell)_\lambda$ and its image in $H^1_{\text{sin}}(K_\lambda, W_p[p^m])$. 

Proposition 3.15. If $v$ is an archimedean place of $K$ then $d(\ell)_v = 0$. 

Proof. The quadratic field $K$ is imaginary, hence $K_v = \mathbb{C}$. The proposition follows because $\mathbb{C}$ is algebraically closed and so $H^1(\mathbb{C}, W_p[p^m]) = 0$. □
Proposition 3.16. If \( v \) is a finite place of \( K \) not dividing \( S' \ell \) then
\[
d(\ell)_v \in H^1_f(K_v, W_p[p^m]).
\]

Proof. By construction, \( P(\ell) \) belongs to \( H^1_f(K_{S'}, W_p[p^m]) \). If \( \ell \nmid p \) is a prime of \( K \) and \( \nu \) is a prime of \( K_{S'} \) above it then \( P(\ell) \) belongs to \( H^1_{un}(K_{S',\nu}, W_p[p^m]) \). By definition, the restriction of \( d(\ell)_v \) is \( P(\ell) \). In particular, the restriction of \( d(\ell)_v \) under the map
\[
H^1(K_v, W_p[p^m]) \to H^1(K_{S',\nu}, W_p[p^m])
\]
lies in \( H^1_{un}(K_{S',\nu}, W_p[p^m]) \). By inflation-restriction, the kernel of the above map is
\[
H^1(K_{S',\nu}/K_v, W_p[p^m](K_{S',\nu})),
\]
and the extension \( K_{S',\nu}/K_v \) is unramified, therefore \( d(\ell)_v \) is unramified too. On the other hand, if \( v \mid p \) then the claim follows from the de Rham conjecture for open varieties (now a theorem of Faltings), as explained in \[35, \text{Lemma 11.1}, (2)]\.

Now we begin the study of \( d(\ell)_\lambda \) (recall that \( \lambda \) is the unique prime of \( K \) above the prime number \( \ell \in S_{pm} \)). For this, we need some preliminaries.

Lemma 3.17. If \( \ell \in S_{pm} \) then there are isomorphisms of \( \mathcal{O}_p \)-modules
\[
H^1_{sin}(K_{\lambda}, W_p[p^m]) \cong \mathcal{O}_p/p^m \mathcal{O}_p, \quad H^1_f(K_{\lambda}, W_p[p^m]) \cong \mathcal{O}_p/p^m \mathcal{O}_p.
\]

Proof. This is \[10, \text{Lemma 6.9}, (2)]\ (Notice that the first three conditions listed on \[10, \text{p. 36}]\ are equivalent to the condition \( \ell \in S_{pm} \) by \[10, \text{Remark 3.1}]\ and that the fourth condition on \[10, \text{p. 36}]\ plays no role in the proof of \[10, \text{Lemma 6.9}]\).

Lemma 3.18. If \( \ell \in S_{pm} \) then the expressions \( (a_\nu \pm (\ell + 1) \text{Frob}_\lambda)/(p^m) \) define endomorphisms of \( H^1_{sin}(K_{\lambda}, W_p[p^m]) \). Furthermore, if \( (a_\nu \pm (\ell + 1))/(p^m) \) are both \( p \)-adic units then the above maps are invertible.

Proof. Since \( \ell \in S_{pm} \), there is an equality \( \text{Frob}_\ell = \text{Frob}_\infty \) of conjugacy classes in \( \text{Gal}(K/\mathbb{Q}) \), so \( \text{Frob}_\lambda \) acts on \( H^1_{sin}(K_{\lambda}, W_p[p^m]) \) as multiplication by \( \pm 1 \). Then Lemma \[5.10] shows that \( (a_\nu \pm (\ell + 1)/(p^m) \) are indeed well-defined endomorphisms of the \( \mathcal{O}_p/p^m \mathcal{O}_p \)-module \( H^1_{sin}(K_{\lambda}, W_p[p^m]) \), and the last claim is obvious.

In the proof of the next result we use the isomorphism \( \nu_\lambda \) defined in \[32\] (keep Remarks \[2.9\] and \[3.4\] in mind for our notational conventions).

Proposition 3.19. Suppose that \( \ell \in S_{pm} \) and that \( (a_\nu \pm (\ell + 1))/(p^m) \) are both \( p \)-adic units. Then \( d(\ell)_\lambda \neq 0 \) in \( H^1_{sin}(K_{\lambda}, W_p[p^m]) \) if and only if \( \text{D}_\kappa(y_{S,p})_\lambda \neq 0 \) in \( H^1_f(K_{\lambda}, W_p[p^m]) \).

Proof. Applying the Key Formula in \[55, \text{[9]}\] with \( y \) a 1-cocycle representing \( \text{D}_\kappa(y_{S,p}) \), and using Proposition \[5.13\] plus the relations \( \ell + 1 \equiv a_\nu \equiv 0 \) (mod \( p^m \)) to simplify the right hand side, we get
\[
\frac{(-1)^{k/2-1}a_\nu a_\nu - (\ell + 1)}{p^m} d(\ell)_{\lambda,\sin} = \frac{a_\nu - (\ell + 1) \text{Frob}_\lambda}{p^m} \left( \nu_\lambda \left( \text{D}_\kappa(y_{S,p})_\lambda \right) \right) \pmod{p^m}.
\]
(Note the difference of sign with respect to \textit{loc. cit.;} the correction can be found in \[39, \text{Proposition 5.16}]\.) But \( \frac{(-1)^{k/2-1}a_\nu a_\nu - (\ell + 1)}{p^m} \in (\mathcal{O}_p/p^m \mathcal{O}_p)^\times \) by assumption, and the proposition follows because \( \frac{a_\nu - (\ell + 1) \text{Frob}_\lambda}{p^m} \) is invertible on \( H^1_{sin}(K_{\lambda}, W_p[p^m]) \) by Lemma \[3.18\].

Recall that the data \( (p^m, S, \text{D}_\kappa, \ell) \) satisfy Assumption \[3.11\] As before, \( L_m \) is the field \( K(W_p[p^m]) \) and \( S' \) is the conductor of \( \text{D}_\kappa \). Define
\[
H^1_f(S', K, W_p[p^m]) := \text{ker} \left( H^1_f(K, W_p[p^m]) \to \bigoplus_{v \mid S'} H^1_f(K_v, W_p[p^m]) \right).
\]
The following result is the counterpart of [13, Proposition 4.10].

**Proposition 3.20.** The class $d(\ell)_\lambda$ lies in the kernel of
\[
\phi_\lambda : H^1_s(K_\lambda, W_p[p^m])^{\psi_\lambda} \rightarrow (H^1_{f,S'}(K, W_p[p^m]))^{\psi_\lambda}
\]
for all $m \geq 1$.

**Proof.** To begin with, $d(\ell)_\lambda \in H^1_s(K_\lambda, W_p[p^m])^{\psi_\lambda}$ by Proposition 3.13. Pick an element $s \in H^1_{f,S'}(K, W_p[p^m])$, so that $s_\lambda \in H^1_f(K_\lambda, W_p[p^m])$; we need to show that
\[
\langle s_\lambda, d(\ell)_\lambda \rangle = 0.
\]
By [10, Proposition 2.2, (2)], one has
\[
\sum_v \langle s_v, d(\ell)_\lambda \rangle_v = 0,
\]
where the sum is taken over all (finite) places of $K$. Now observe that if $v \nmid S'\ell$ then $\langle s_v, d(\ell)_\lambda \rangle_v = 0$ by Proposition 3.16. On the other hand, if $v | S'$ then $s_v = 0$ because $s \in H^1_{f,S'}(K, W_p[p^m])$. Therefore (30) is an immediate consequence of (37). □

3.10. Applications of Čebotarev’s density theorem. Recall that $L_m$ is the composite of $K$ and the field $\mathbb{Q}(\ker(\overline{\vartheta}_{p,m}))$ fixed by $\ker(\overline{\vartheta}_{p,m})$. Similarly, define $L_{S,m} := K_S(W_p[p^m])$ to be the composite of $K_S$ and $\mathbb{Q}(\ker(\overline{\vartheta}_{p,m}))$.

We need some cohomological lemmas.

**Lemma 3.21.** $H^i(\text{Gal}(L_m/K), W_p[p^m]) \simeq H^i(\text{Gal}(L_{S,m}/K_S), W_p[p^m])$ for all $i \geq 0$.

**Proof.** The fields $K$ and $\mathbb{Q}(W_p[p^m])$ are linearly disjoint over $\mathbb{Q}$, and the same is true of $K_S$ and $\mathbb{Q}(W_p[p^m])$. This holds because $\mathbb{Q}(W_p[p^m]) \cap K$ and $\mathbb{Q}(W_p[p^m]) \cap K_S$ are extensions of $\mathbb{Q}$ that are everywhere unramified, which is a consequence of the fact that $\mathbb{Q}(W_p[p^m])/\mathbb{Q}$ is unramified outside $Np$ while $K_S/\mathbb{Q}$ is unramified outside $SD$ and $(pN, SD) = 1$. It follows that the restriction maps induce canonical isomorphisms
\[
\text{Gal}(L_m/K) \simeq \text{Gal}(\mathbb{Q}(W_p[p^m])/\mathbb{Q}), \quad \text{Gal}(L_{S,m}/K_S) \simeq \text{Gal}(\mathbb{Q}(W_p[p^m])/\mathbb{Q}).
\]
Therefore both groups appearing in the statement of the lemma are isomorphic to
\[
H^1(\text{Gal}(\mathbb{Q}(W_p[p^m])/\mathbb{Q}), W_p[p^m]),
\]
and this concludes the proof. □

**Lemma 3.22.** $H^i(\text{Gal}(L_m/K), W_p[p^m]) = 0$ for all $i \geq 0$.

**Proof.** This is [10, Proposition 6.3, (2)]. □

**Lemma 3.23.** The restriction map
\[
H^1(K, W_p[p^m]) \rightarrow H^1(K_S, W_p[p^m])
\]
is injective.

**Proof.** By the inflation-restriction exact sequence, the kernel of this map is
\[
H^1(\text{Gal}(K_S/K), W_p[p^m](K_S)),
\]
which is trivial because $W_p[p^m](K_S) = 0$ by part (2) of Lemma 3.9. □

**Lemma 3.24.** The restriction map
\[
H^1(K_S, W_p[p^m]) \rightarrow H^1(L_{S,m}, W_p[p^m])
\]
is injective.
Lemma 3.25. The restriction map
\[ H^1(K, W_p[p^m]) \longrightarrow H^1(L_{S,m}, W_p[p^m]) \]
is injective.

Proof. Combine Lemmas 3.23 and 3.24.

Proposition 3.26. Suppose that
- \( D_n(y_{S,p}) \) is not trivial in \( H^1(K_S, W_p[p^m]) \);
- \( r_{p,m}(H^1_{f,S}(K, W_p[p^m])^{\kappa}) \geq 1 \).

Then there exist infinitely many prime numbers \( \ell \) such that
1. \( \ell \nmid pNDS \) and \( \text{Frob}_y = \text{Frob}_\infty \) in \( \text{Gal}(L_{S,m}/\mathbb{Q}) \);
2. \( \ell + 1 \pm a_\ell \neq 0 \) (mod \( p^{m+1} \));
3. the image of \( D_n(y_{S,p}) \) in \( H^1_{f,S}(K, W_p[p^m]) \) is not zero, where \( \lambda \) is the unique prime of \( K \) above \( \ell \);
4. the map of \( \mathcal{O}_p/p^m \mathcal{O}_p \)-modules
\[ H^1_{f,S}(K, W_p[p^m])^{\kappa} \longrightarrow H^1_{f,S}(K, W_p[p^m])^{\kappa} \]
in surjective.

Proof. By assumption, \( D_n(y_{S,p}) \neq 0 \) in \( H^1(K_S, W_p[p^m]) \), hence Lemma 3.24 implies that the same is true of its image in \( H^1(L_{S,m}, W_p[p^m]) \), denoted by the same symbol. Since \( p \) is odd, \( H^1(L_{S,m}, W_p[p^m]) \) splits as the direct sum of its \( \pm \)-eigenspaces for the action of \( c \in \text{Gal}(K/\mathbb{Q}) \), so there is \( \delta \in \{ \pm \} \) such that the projection of \( D_n(y_{S,p}) \) to the \( \delta \)-eigenspace of \( H^1(L_{S,m}, W_p[p^m]) \) is non-zero. Let us fix such a sign \( \delta \) and write \( d \) for the corresponding projection of \( D_n(y_{S,p}) \).

Let \( s \in H^1_{f,S}(K, W_p[p^m])^{\kappa} \) be an element of exact order \( p^m \), which exists by assumption. By Lemma 3.23, the image of \( s \) in \( H^1(L_{S,m}, W_p[p^m]) \) has order \( p^m \) as well. Since the relevant Galois action is trivial and \( W_p[p^m] \) is abelian, there is a canonical identification
\[ H^1(L_{S,m}, W_p[p^m]) = \text{Hom}(\text{Gal}(L_{S,m}^{ab}/L_{S,m}), W_p[p^m]), \]
where \( L_{S,m}^{ab} \) is the maximal abelian extension of \( L_{S,m} \). Denote by \( \psi \) and \( \varphi \) the homomorphisms corresponding to \( d \) and to the image of \( s \) in \( H^1(L_{S,m}, W_p[p^m]) \), respectively.

Denote by \( \tilde{L}_{S,m} \) the smallest extension of \( L_{S,m} \) that is cut out by \( \psi \) and \( \varphi \) and is Galois over \( \mathbb{Q} \). There is an isomorphism
\[ \text{Gal}(\tilde{L}_{S,m}/K_S) \simeq \text{Gal}(\tilde{L}_{S,m}/L_{S,m}) \times \text{Gal}(L_{S,m}/K_S). \]
Complex conjugation \( c \) acts on \( \text{Gal}(\tilde{L}_{S,m}/L_{S,m}) \) by inner automorphisms, and we denote by \( \text{Gal}(\tilde{L}_{S,m}/L_{S,m})^c \) the subgroup of \( \text{Gal}(\tilde{L}_{S,m}/L_{S,m}) \) that is fixed by \( c \). Set
\[ \Phi := H^1(\text{Gal}(\tilde{L}_{S,m}/L_{S,m}), W_p[p^m]) = \text{Hom}(\text{Gal}(\tilde{L}_{S,m}/L_{S,m}), W_p[p^m]). \]
By definition of \( \tilde{L}_{S,m} \), the maps \( \psi \) and \( \varphi \) factor through \( \text{Gal}(\tilde{L}_{S,m}/L_{S,m}) \) and so determine maps \( \tilde{\psi} \) and \( \tilde{\varphi} \) in \( \Phi \). The group \( \text{Gal}(L_{S,m}/K_S) \) acts canonically on \( \Phi \), and \( \tilde{\psi} \) and \( \tilde{\varphi} \) are fixed by this action as they are restrictions of classes in \( H^1(K_S, W_p[p^m]) \) and \( H^1(K, W_p[p^m]) \), respectively. There is also an action of \( c \) on \( \Phi \) and, since \( s \) belongs to \( H^1(K, W_p[p^m])^{\kappa} \), the map \( \tilde{\varphi} \) belongs to \( \Phi^{\kappa} \), while \( \tilde{\psi} \) belongs to \( \Phi^{\delta} \) by construction.

Now we claim that both \( \tilde{\psi} \) and \( p^{m-1}\tilde{\varphi} \) are non-zero on \( \text{Gal}(\tilde{L}_{S,m}/L_{S,m})^c \). To show this, let \( \tilde{q} \) denote either \( \tilde{\psi} \) or \( p^{m-1}\tilde{\varphi} \). If \( \tilde{q} = 0 \) on \( \text{Gal}(\tilde{L}_{S,m}/L_{S,m})^c \) then \( \tilde{q} \) maps \( \text{Gal}(\tilde{L}_{S,m}/L_{S,m}) \)...
to one of the eigenspaces $W_p[p^m]^{\pm}$; this is true because $\varrho$ factors through the $p$-primary part of $\Gal(L_{S,m}/L_{S,m})$, which splits as the sum of the two eigenspaces for the action of $c$, and $\varrho$ belongs to an eigenspace of $\Phi$. Since $\varrho$ is non-zero and fixed by $\Gal(L_{S,m}/K_S)$, it follows that $\im(\varrho)$ is a non-zero, proper submodule of $W_p[p^m]$ that is stable under the action of $\Gal(L_{S,m}/K_S) \cong \Gal(\mathbb{Q}(W_p[p^m])/\mathbb{Q})$. Multiplying $\im(\varrho)$ by a suitable power of $p$, we obtain a non-zero, proper submodule of $W_p[p]$ that is stable under $\Gal(\mathbb{Q}(W_p[p^m])/\mathbb{Q})$, and this contradicts the irreducibility of $\tilde{\varphi}$ (Lemma 3.17). We conclude that both $p^{m-1}\varphi$ and $\tilde{\varphi}$ are necessarily non-zero on $\Gal(L_{S,m}/L_{S,m})^+$. It follows that we can find $g \in \Gal(L_{S,m}/L_{S,m})^+$ such that $\tilde{\varphi}(g) \neq 0$ and $\varphi(g)$ has exact order $p^m$. Let $\ell$ be a prime number unramified in $L_{S,m}/\mathbb{Q}$ such that

$$\ell \nmid NDSp, \quad \Frob_\ell = \Frob_\infty g.$$ 

Here $\Frob_\infty g$ denotes the conjugacy class of $cg$ in $\Gal(L_{S,m}/\mathbb{Q})$. By Čebotarev’s density theorem, the set of primes satisfying (38) is infinite.

Clearly, (1) is satisfied by any $\ell$ as in (38). In particular, $\ell$ is inert in $K$ and we denote by $\lambda$ the unique prime of $K$ above $\ell$, which splits completely in $L_{S,m}$ (10 Lemma 6.7). Choose a prime $\tilde{\lambda}_{S,m}$ of $L_{S,m}$ above $\ell$ such that $\Frob_{\tilde{\lambda},S,m/\ell} = cg$ and let $\lambda_{S,m}$ be the prime of $L_{S,m}$ below $\tilde{\lambda}_{S,m}$; the completion $L_{\lambda_{S,m}}$ of $L_{S,m}$ at $\lambda_{S,m}$ is then equal to $\tilde{\lambda}_{S,m}$.

Now we show that every prime $\ell$ satisfying (38) satisfies also (3) and (4) in the statement of the proposition. If $g = \tilde{\varphi}$ or $g = p^{m-1}\varphi$ then, since $g' = g$, one has

$$g(Frob_{\lambda_{S,m}}) = g(Frob_{\lambda_{S,m}}^2) = g(g'g) = g(g^2) \neq 0.$$ 

Therefore the restriction of $g$ to $\Gal(L_{\lambda_{S,m}}/L_{\lambda_{S,m}})$ is non-zero and hence, since $L_{\lambda_{S,m}} = K_{\lambda}$, taking $g = \tilde{\varphi}$ gives (3). As for (4), note that, by Lemma 3.17, it suffices to find an element of $H^1_{L,S}(K_{\lambda}, W_p[p^m])^{\psi}$ whose image in $H^1_{L}(K_{\lambda}, W_p[p^m])^{\psi}$ has exact order $p^m$. But it follows from (39) with $g = p^{m-1}\varphi$ that the order of the image of $s$ in $H^1_{L}(K_{\lambda}, W_p[p^m])^{\psi}$ is $p^m$, and we are done.

Finally, we show that one can choose infinitely many primes $\ell$ as in (38) such that (2) is true. Fix a prime $\ell'$ satisfying (38) but not (2), so that $\ell' + 1 \equiv a_{\ell'} \pmod{p^{m+1}}$ for a suitable $\epsilon \in \{\pm 1\}$. It is known that $\tr(F_{\ell'}|A_p) = a_{\ell'}/\ell'^{k/2}-1$ and $\det(F_{\ell'}|A_p) = \ell'$. Take any $\alpha \in \mathbb{Z}_p^\times$ such that $\alpha \equiv 1 \pmod{p^m}$ and set $M := \begin{pmatrix} a & 0 \\ 0 & 0 \end{pmatrix}$. By (10) Lemma 6.2, the matrix $M$ lies in the image of the representation $\vartheta_p$ of $G_{\mathbb{Q}}$ on $A_p$, hence there is $\sigma_\alpha \in G_{\mathbb{Q}}$ having $M$ as its image. Then

$$\tr(F_{\ell'} \sigma_\alpha | A_p) = \alpha a_{\ell'}/\ell'^{k/2}-1, \quad \det(F_{\ell'} \sigma_\alpha | A_p) = \alpha^2 \ell'.$$

Let $\ell$ be a prime such that $\ell \nmid NDSp$ and $\Frob_\ell = \Frob_{\ell'} \sigma_\alpha | L_{S,m+1}$ in $\Gal(L_{S,m+1}/\mathbb{Q})$, where we denote by $\Frob_{\ell'} \sigma_\alpha | L_{S,m+1}$ the conjugacy class of $f \cdot \sigma_\alpha | L_{S,m+1}$ for any choice of $f \in \Frob_{\ell'}$. Again, Čebotarev’s density theorem guarantees that there exist infinitely many such $\ell$. Then

$$a_{\ell'}/\ell'^{k/2}-1 = \alpha a_{\ell'}/\ell'^{k/2}-1 \pmod{p^{m+1}}, \quad \ell' \equiv \alpha^2 \ell' \pmod{p^{m+1}},$$

and one deduces that there exists an $\alpha$ as above such that $\ell + 1 \pm a_{\ell'} \neq 0 \pmod{p^{m+1}}$. This shows that $\ell$ satisfies (2). But the image of $\Frob_\ell$ in $\Gal(L_{S,m}/\mathbb{Q})$ is equal to that of $\Frob_{\ell'}$, and so $\ell$ satisfies (38) too.

3.11. Divisibility properties of Heegner cycles. The arguments in this subsection follow those in [10] §5.1. As before, $\ell$ belongs to $\mathcal{S}_p^{\infty}$ and $\lambda$ is the unique prime of $K$ above $\ell$. Moreover, recall the shorthand $\mathbb{F}_p = \mathbb{Z}/p\mathbb{Z}$ and for any $\mathcal{O}_p/p^m\mathcal{O}_p$-module $M$ set

$$r_p(M) := \dim_{\mathbb{F}_p}(M \otimes_{\mathcal{O}_p/p^m\mathcal{O}_p} \mathbb{F}_p).$$

To use uniform notations, put also $r_p := r_p,1$. 
Lemma 3.27. \( r_p(H^1_f(K, W_p[p^m])) \leq 1 \).

Proof. To ease notations, in this proof we use the symbol \( \otimes \) to denote tensorization over \( \mathcal{O}_p/p^m\mathcal{O}_p \). With this convention in mind, note that for any \( \mathcal{O}_p/p^m\mathcal{O}_p \)-module \( M \) equipped with an action of \( \text{Gal}(K/\mathbb{Q}) \) there are injections

\[
M^\pm \otimes \mathbb{F}_p \hookrightarrow (M \otimes \mathbb{F}_p)^\pm.
\]

If \( \hat{\mathbb{Z}} \) is the profinite completion of \( \mathbb{Z} \) then \( \text{Gal}(K_{\mathbb{N}}/K) \simeq \hat{\mathbb{Z}} \), hence well-known results in group cohomology (see, e.g., [48, Ch. XIII, Proposition 1]) show that there is a short exact sequence

\[
0 \longrightarrow (\text{Frob}_\lambda - 1)W_p[p^m] \longrightarrow W_p[p^m] \longrightarrow H^1_f(K, W_p[p^m]) \longrightarrow 0.
\]

Tensoring (41) with \( \mathbb{F}_p \) produces an exact sequence

\[
(\text{Frob}_\lambda - 1)W_p[p^m] \otimes \mathbb{F}_p \longrightarrow W_p[p^m] \otimes \mathbb{F}_p \longrightarrow H^1_f(K, W_p[p^m]) \otimes \mathbb{F}_p \longrightarrow 0.
\]

By [10, Proposition 6.3, (4)], \( W_p[p^m]^\pm \) is free of rank 1 over \( \mathcal{O}_p/p^m\mathcal{O}_p \), and then (40) with \( M = W_p[p^m] \) gives

\[
\text{dim}_{\mathbb{F}_p}((W_p[p^m] \otimes \mathbb{F}_p)^\pm) = 1.
\]

If \( \text{im}(\iota) = 0 \) then (42) induces isomorphisms

\[
(W_p[p^m] \otimes \mathbb{F}_p)^\pm \simeq (H^1_f(K, W_p[p^m]) \otimes \mathbb{F}_p)^\pm,
\]

and the inequalities \( r_p(H^1_f(K, W_p[p^m])^\pm) \leq 1 \) follow by combining (43), (44) and (40) with \( M = H^1_f(K, W_p[p^m]) \). Finally, \( W_p[p^m] \otimes \mathbb{F}_p \) has dimension 2 over \( \mathbb{F}_p \), so if \( \text{im}(\iota) \neq 0 \) then (42) implies that \( r_p(H^1_f(K, W_p[p^m])) \leq 1 \) and, \( a \text{ fortiori} \), \( r_p(H^1_f(K, W_p[p^m])^\pm) \leq 1 \). \( \square \)

Remark 3.28. If \( \ell \in \tilde{S}_p^m \) then Lemma 3.17 shows that equality holds in Lemma 3.27.

To simplify our notation, for every integer \( S' > 1 \) define

\[
A(S') := \bigoplus_{\lambda | S'} H^1_f(K, W_p[p^m]).
\]

Of course, the module \( A(S') \) depends on \( m \), but no confusion is likely to arise.

Lemma 3.29. If \( \ell \in \tilde{S}_p^m \) then

\[
r_{p,m}(H^1_{f,S'}(K, W_p[p^m])^\pm) \leq r_{p,m}(H^1_{f,S'\ell}(K, W_p[p^m])^\pm) + r_p(A(S'\ell)^\pm) - r_p(A(S')^\pm).
\]

Proof. There is an exact sequence

\[
0 \longrightarrow H^1_{f,S'}(K, W_p[p^m])^\pm \longrightarrow H^1_{f,S'\ell}(K, W_p[p^m])^\pm \longrightarrow H^1_f(K, W_p[p^m])^\pm
\]

where \( \lambda \) is the prime of \( K \) above \( \ell \). Combining part (3) of Lemma 3.4 and the obvious inequality

\[
r_{p,m}(H^1_f(K, W_p[p^m])^\pm) \leq r_p(H^1_f(K, W_p[p^m])^\pm)
\]

we find

\[
r_{p,m}(H^1_{f,S'}(K, W_p[p^m])^\pm) \leq r_{p,m}(H^1_{f,S'\ell}(K, W_p[p^m])^\pm) + r_p(H^1_f(K, W_p[p^m])^\pm).
\]

Applying Lemma 3.27 to the above inequality yields

\[
r_{p,m}(H^1_{f,S'}(K, W_p[p^m])^\pm) \leq r_{p,m}(H^1_{f,S'\ell}(K, W_p[p^m])^\pm) + 1.
\]

Now \( \ell \) belongs to \( \tilde{S}_p^m \), so by Lemma 3.17 one has

\[
r_p(H^1_f(K, W_p[p^m])^\pm) = 1,
\]

and we deduce that

\[
r_p(A(S'\ell)^\pm) = r_p(A(S')^\pm) + 1.
\]
Hence inequality (46) becomes
\[ r_{p,m}(H^1_{f,S'}(K, W_p[p^m])^\pm) \leq r_{p,m}(H^1_{f,S'}(K, W_p[p^m])^\pm) + r_p(A(S')^\pm) - r_p(A(S')^\pm), \]
as was to be shown.

**Proposition 3.30.** Let \( D_\kappa \) be a derivative of support \( S \) and conductor \( S' \). If
\[ \text{ord}(D_\kappa) < r_{p,m}(H^1_{f,S'}(K, W_p[p^m])^\kappa) + r_p(A(S')^\kappa) \]
then \( D_\kappa(y_{S,p}) \equiv 0 \pmod{p^m} \).

**Proof.** Define the weight of \( D_\kappa \) to be
\[ \text{wt}(D_\kappa) := \text{ord}(D_\kappa) - \# \{ \ell \text{ prime number} | \ell \mid S \text{ and } \ell \in \tilde{S}_{p^m} \}. \]
The proof the proposition we proceed by induction on \( \text{wt}(D_\kappa) \).

First of all, observe that if \( \text{wt}(D_\kappa) < 0 \) then the result is true. Indeed, in this case \( D_\kappa \) contains at least one factor of the form \( D^{\kappa'} \) for some prime \( \ell \in \tilde{S}_{p^m} \). By part (1) of Proposition 3.1 and the relation (II) between restriction, corestriction and Galois trace, we have
\[ D^{\kappa'}(y_{T,p}) = \text{res}_{K_T/K_\kappa}(y_{T,p}) \cdot (a_\ell/p^{k/2-1}) \equiv 0 \pmod{p^m}, \]
where the congruence holds because \( \ell \in \tilde{S}_{p^m} \) (here \( \text{res}_{K_T/K_\kappa} \) denotes the restriction map in cohomology from \( H^1(K_T, A_\kappa) \) to \( H^1(K_\kappa, A_\kappa) \)). Then the result follows (without assuming any condition on the order of \( D_\kappa \)).

Now set \( k := \text{wt}(D_\kappa) \) and assume by induction that the theorem is true for all derivatives \( D_{\kappa'} \) such that \( \text{wt}(D_{\kappa'}) < k \). We argue by contradiction, supposing that
\[ D_{\kappa}(y_{S,p}) \equiv 0 \pmod{p^m}. \]
We first show that the inequality in the statement of the proposition plus (47) imply that
\[ r_{p,m}(H^1_{f,S'}(K, W_p[p^m])^{\kappa'}) \geq 1. \]
In fact, if this were not the case then there would be an inequality
\[ \text{ord}(D_\kappa) < r_p(A(S')). \]
By Lemma 3.27, the right hand side of this inequality is less than or equal to the number of primes dividing \( S' \); but each of them contributes at least for 1 unity in the sum defining \( \text{ord}(D_\kappa) \), so the above inequality does not occur and we conclude that (48) holds.

Equations (47) and (48) show that the assumptions in Proposition 3.26 are fulfilled and therefore, with the usual notation, one can find a prime number \( \ell \) such that
\begin{itemize}
  \item \( \ell \nmid pNDS \) and \( \text{Frob}_\ell = \text{Frob}_\infty \) in \( \text{Gal}(L_{S,m}/Q) \);
  \item \( p^{m+1} | (\ell + 1) \pm a_\ell \);
  \item the image of \( D_{\kappa}(y_{S,p}) \) in \( H^1_f(K_\lambda, W_p[p^m]) \) is not zero;
  \item the map of \( O_p/p^mO_p \)-modules
    \[ H^1_{f,S'}(K_\lambda, W_p[p^m])^{\kappa'} \rightarrow H^1_f(K_\lambda, W_p[p^m])^{\kappa'} \]
    is surjective.
\end{itemize}
Dualizing the map in (49) and using (32) and (34), we see that the map
\[ \phi_\lambda : H^1_{sin}(K_\lambda, W_p[p^m])^{\kappa'} \rightarrow (H^1_{f,S'}(K, W_p[p^m])^{\kappa'})^{\kappa'} \]
is injective. Now we want to show that the derivative \( D_\kappa D^1_\ell \) satisfies Assumption 3.11. Fix \( D_{\kappa'} \) strictly less than \( D_\kappa D^1_\ell \). Then
\[ \text{ord}(D_{\kappa'}) < \text{ord}(D_\kappa D^1_\ell) = \text{ord}(D_\kappa) + 1, \]
hence
\[ \text{ord}(D_{\kappa'}) \leq \text{ord}(D_\kappa). \]
By Lemma 3.29 one has
\[ r_{p,m}(H^1_f(S)(K, W_p[p^m])^{\epsilon_s}) \leq r_{p,m}(H^1_f(S)(K, W_p[p^m])^{\epsilon_s}) + r_p(A(S'(\ell)^{\epsilon_s}) - r_p(A(S')^{\epsilon_s}). \]
Combining this inequality with the one in the statement of the proposition we find
\[ \text{ord}(D_\kappa) < r_{p,m}(H^1_f,S(\epsilon)(K, W_p[p^m])^{\epsilon_s}) + r_p(A(S')^{\epsilon_s}). \]
and therefore, applying (51), we get
\[ \text{ord}(D_{\kappa'}) < r_{p,m}(H^1_f,S(\epsilon)(K, W_p[p^m])^{\epsilon_s}) + r_p(A(S')^{\epsilon_s}). \]
Furthermore, since the support of \( D_{\kappa'} \) is divisible by an extra prime \( \ell \in \tilde{S}_{p,m} \), we see that
\[ \text{wt}(D_{\kappa'}) < \text{wt}(D_\kappa). \]
Equations (52) and (53) show that \( D_{\kappa'} \) satisfies the induction hypothesis, and we conclude that \( D_{\kappa'}(y_{S\ell,p}) \equiv 0 \pmod{p^m} \). This shows that Assumption 3.11 is satisfied in our setting, hence we may apply the construction of 3.6 and obtain a class \( d(\ell) \in H^1(K, W_p[p^m]) \). Since the image of \( D_\kappa(y_{S\ell,p}) \) in \( H^1_f(K, W_p[p^m]) \) is not zero, it follows from Proposition 3.19 (which we can apply because \( p^m+1 \mid \ell + 1 + \alpha \ell \)) that the image of \( d(\ell) \) in \( H^1_{\text{sing}}(K, W_p[p^m]) \) is non-zero. Therefore, since \( d(\ell) \) belongs to the \( c_r \)-eigenspace for \( c \) thanks to Proposition 3.13, Proposition 3.20 ensures that the map
\[ \phi_\lambda : H^1_{\text{sing}}(K, W_p[p^m])^{\epsilon_s} \rightarrow (H^1_f(S)(K, W_p[p^m])^{\epsilon_s}). \]
is not injective. But this contradicts (50), and the proposition is proved. \( \square \)

Now we keep notations and assumptions as in Proposition 3.30 and prove two corollaries.

Corollary 3.31. If
\[ \text{ord}(D_\kappa) < r_{p,m}(H^1_f,S(\epsilon)(K, W_p[p^m])^{-\epsilon_s}) + r_p(A(S')^{-\epsilon_s}) - 1 \]
and \( \text{ord}(D_\kappa) < p \) then \( D_\kappa(y_{S\ell,p}) \equiv 0 \pmod{p^m} \).

Proof. Suppose \( D_\kappa(y_{S\ell,p}) \neq 0 \pmod{p^m} \) and pick a prime \( \ell \) such that \( \text{Frob}_\ell = \text{Frob}_\infty \) in \( \text{Gal}(L_{S,m}/\mathbb{Q}) \) and the image of \( D_\kappa(y_{S\ell,p}) \) in \( H^1_f(K, W_p[p^m]) \) is not zero (that such a choice is possible can be checked along the same lines as in the proof of Proposition 3.26 and the arguments are actually simpler).

Now we show that
\[ D_\kappa D^1_f(y_{S\ell,p}) \text{ is not zero in } H^1(K, W_p[p^m]). \]
If there is a derivative \( D_{\kappa'} \) strictly less than \( D_\kappa D^1_f \) such that \( D_{\kappa'}(y_{S\ell,p}) \) is not zero in \( H^1(K, W_p[p^m]) \), using formula 21 recursively one easily shows that (54) holds (use here the fact that \( \text{ord}(D_\kappa) < p \)). On the contrary, if for all derivatives \( D_{\kappa'} \) strictly less than \( D_\kappa D^1_f \) we have \( D_{\kappa'}(y_{S\ell,p}) = 0 \) in \( H^1(K, W_p[p^m]) \) then one can construct the class \( d(\ell) \) which, by Proposition 3.19, is not locally trivial at \( \lambda \). Hence, a fortiori, \( d(\ell) \) is not globally trivial, and therefore also \( P(\ell) = D_\kappa D^1_f(y_{S\ell,p}) \) is not trivial.

At this point we make use of our assumptions. Since
\[ \text{ord}(D_\kappa D^1_f) = \text{ord}(D_\kappa) + 1, \]
it follows that
\[ \text{ord}(D_\kappa D^1_f) < r_{p,m}(H^1_f,S(\epsilon)(K, W_p[p^m])^{-\epsilon_s}) + r_p(A(S')^{-\epsilon_s}). \]
By Lemma 3.29 the right hand side of the above inequality is less than or equal to
\[ r_{p,m}(H^1_f,S(\epsilon)(K, W_p[p^m])^{-\epsilon_s}) + r_p(A(S')^{-\epsilon_s}), \]
and therefore we obtain the inequality
\[ \text{ord}(D_\kappa D^1_f) < r_{p,m}(H^1_f,S(\epsilon)(K, W_p[p^m])^{-\epsilon_s}) + r_p(A(S')^{-\epsilon_s}). \]
By \( \langle 53 \rangle \), we have \((-1)^{\text{ord}(D, \mathcal{D})} = -\epsilon_R \). Therefore we can apply Proposition \( \langle 3.39 \rangle \) which shows that \( D, \mathcal{D} \langle y_{S_{\ell, p}} \rangle \equiv 0 \pmod{p^m} \). In light of \( \langle 53 \rangle \), this is a contradiction.

\[
\text{Corollary 3.32. If one of the two conditions}
\]

(1) \( \text{ord}(D, \mathcal{D}) < r_{p, m}(H^j_{\mathcal{I}}(K, W_p[p^m])^{\epsilon_s}) \),

(2) \( \text{ord}(D, \mathcal{D}) < r_{p, m}(H^1_{\mathcal{I}}(K, W_p[p^m])^{\epsilon_s}) - 1 \) and \( \text{ord}(D, \mathcal{D}) < p \)

holds then \( D, \mathcal{D} \langle y_{S_{\ell, p}} \rangle \equiv 0 \pmod{p^m} \).

\[
\text{Proof. Part (3) of Lemma \( \langle 3.4 \rangle \) implies that}
\[
\text{ord}(D, \mathcal{D}) < r_{p, m}(H^j_{\mathcal{I}}(K, W_p[p^m])^{\epsilon_s}) \leq r_{p, m}(H^1_{\mathcal{I}}(K, W_p[p^m])^{\epsilon_s}) + r_p(A(S')^{\epsilon_s}).
\]

The corollary follows from Proposition \( \langle 3.30 \rangle \) if condition (1) holds and from Corollary \( \langle 3.31 \rangle \) if condition (2) holds.

We are now in a position to state and prove the main result of this section.

\[
\text{Theorem 3.33. Let } S \text{ be a square-free product of primes in } S_{p^m}. \text{ If } \text{ord}(D, \mathcal{D}) < \min\{r_{p, m}, p\} \text{ then } D, \mathcal{D} \langle y_{S_{\ell, p}} \rangle \equiv 0 \pmod{p^m}.
\]

\[
\text{Proof. Since } \text{ord}(D, \mathcal{D}) < r_{p, m} \text{ and}
\]

\[
r_{p, m} = r_{p, m}(H^1_{\mathcal{I}}(K, W_p[p^m])^{\epsilon_s}) + r_{p, m}(H^1_{\mathcal{I}}(K, W_p[p^m])^{\epsilon_s}),
\]

at least one of the conditions in Corollary \( \langle 3.32 \rangle \) is satisfied (in (2) we also need the condition \( \text{ord}(D, \mathcal{D}) < p \), which is not needed for (1)), and we are done.

4. Theta elements and refined Beilinson–Bloch conjecture

In this section we prove our main result on the order of vanishing of certain combinations of Heegner cycles.

4.1. Theta elements and arithmetic L-functions. For any square-free product \( T \) of prime numbers belonging to the set \( S \) defined in \( \langle 1.7 \rangle \) consider the resolvent element

\[
\theta_{T, p} := \sum_{\sigma \in G_T} \sigma(y_{T, p}) \otimes \sigma \in \Lambda_p(K_T) \otimes_{\mathcal{O}_p} \mathcal{O}_p[G_T].
\]

Our main result relates these elements to the dimension of \( X_p(K) \) over \( F_p \).

We also need to introduce suitable variants and combinations of the above elements. To begin with, we trace them down to \( K \) as follows. As in \( \langle 3.0 \rangle \) fix any lift \( N_T \in \mathbb{Z}[\Gamma_T] \) of the norm \( N = \sum_{\sigma \in \Gamma_1} \sigma \); in other words, for every \( \sigma \in \Gamma_1 \) choose \( \sigma' \in \Gamma_T \) such that \( \sigma'|_{\Gamma_1} = \sigma \).

Define

\[
\zeta_{T, p} := N_T(\theta_{T, p}) = \sum_{\sigma \in G_T} \sigma N_T(y_{T, p}) \otimes \sigma \in \Lambda_p(K_T) \otimes_{\mathcal{O}_p} \mathcal{O}_p[G_T].
\]

Note that these elements depend on the choice of \( N_T \), but for simplicity we shall drop this dependence from the notation.

Let \( x \mapsto x^* \) denote the involution of \( \mathcal{O}_p[G_T] \) induced by the map \( \sigma \mapsto \sigma^{-1} \) on \( G_T \) and denote by \( \zeta_{T, p}^* \) the element obtained by applying to \( \zeta_{T, p} \) the map induced by this involution.

Fix a square-free product \( S \) of primes belonging to \( S \). As before, fix a lift \( N_S \) of \( N \) to \( \mathbb{Z}[\Gamma_S] \).

By projection, this gives lifts \( N_T \) for all \( T | S \) that may be used to define \( \zeta_{T, p} \) and \( \zeta_{T, p}^* \) as in \( \langle 56 \rangle \). Since the extension \( K_S/\mathbb{Q} \) is generalized dihedral and hence solvable, part (1) of Lemma \( \langle 3.9 \rangle \) ensures that \( \Lambda_p(K_S) = 0 \), so for every \( T | S \) the inflation-restriction exact sequence yields an injection \( \Lambda_p(K_T) \rightarrow \Lambda_p(K_S) \). On the other hand, the natural inclusion \( G_T \subset G_S \) (see \( \langle 3.1 \rangle \)) induces an injection \( \mathcal{O}_p[G_T] \rightarrow \mathcal{O}_p[G_S] \) of (free) \( \mathcal{O}_p \)-modules, and therefore we obtain an injection

\[
\Lambda_p(K_T) \otimes_{\mathcal{O}_p} \mathcal{O}_p[G_T] \hookrightarrow \Lambda_p(K_S) \otimes_{\mathcal{O}_p} \mathcal{O}_p[G_S].
\]
of $\mathcal{O}_p$-modules. Furthermore, the canonical inclusion $G_S \subset \Gamma_S$ induces an injection
\begin{equation}
\Lambda_p(K_S) \otimes \mathcal{O}_p \mathcal{O}_p[G_S] \hookrightarrow \Lambda_p(K_S) \otimes \mathcal{O}_p \mathcal{O}_p[\Gamma_S]
\end{equation}
of $\mathcal{O}_p$-modules. The composition of (57) and (58) allows us to view $\zeta_T, p$ and $\zeta^*_T, p$ as elements of $\Lambda_p(K_S) \otimes \mathcal{O}_p \mathcal{O}_p[\Gamma_S]$, which from here on we shall do without any further warning.

For $S$ fixed as above and every $T \mid S$ set
\begin{equation}
a_T := \mu(T) \sum_{\sigma \in \text{Gal}(K_S/K_T)} \sigma, \quad a_T^* := \chi_K(T)a_T
\end{equation}
where $\mu$ is the M"obius function and $\chi_K$ is the quadratic character attached to $K$. Define the arithmetic $L$-function attached to $S$ and $p$ as
\begin{equation}
L_{S,p} := \left( \sum_{T \mid S} a_T \zeta_{T,p} \right) \otimes \left( \sum_{T \mid S} a_T^* \zeta_{T,p}^* \right) \in \Lambda_p(K_S)^{\otimes 2} \otimes \mathcal{O}_p \mathcal{O}_p[\Gamma_S].
\end{equation}

Here we are using the canonical identification
\begin{equation}
\Lambda_p(K_S)^{\otimes 2} \otimes \mathcal{O}_p \mathcal{O}_p[\Gamma_S] = (\Lambda_p(K_S) \otimes \mathcal{O}_p \mathcal{O}_p[\Gamma_S]) \otimes (\Lambda_p(K_S) \otimes \mathcal{O}_p \mathcal{O}_p[\Gamma_S]),
\end{equation}
the superscript "$\otimes 2$" denoting tensorization over $\mathcal{O}_p$. Note that if $T \mid S$ and
\begin{equation}
\mu_{S,T} : \Lambda_p(K_S)^{\otimes 2} \otimes \mathcal{O}_p \mathcal{O}_p[\Gamma_S] \rightarrow \Lambda_p(K_S)^{\otimes 2} \otimes \mathcal{O}_p \mathcal{O}_p[\Gamma_T]
\end{equation}
is the map induced by the canonical projection $\Gamma_S \rightarrow \Gamma_T$ then
\begin{equation}
\mu_{S,T}(L_{S,p}) = L_{T,p} \cdot \prod_{\ell / (S/T)} (1 + \ell - a_\ell / \ell^{k/2-1}) \cdot (1 + \ell + a_\ell / \ell^{k/2-1}).
\end{equation}

Remark 4.1. One could define an element $L_{S,p}$ as in (60) by replacing the coefficients $a_T$ and $a_T^*$ with any choice of $b_T$ and $b_T'$ in $\mathcal{O}_p[\Gamma_S]$, obtaining compatibility relations similar to (61). Our preference is motivated by the existence, still only conjectured, of a Mazur–Tate type regulator $\text{Reg}(S)$ that satisfies proper properties analogous to those of the regulator defined in [32] and appearing in [18]. This regulator $\text{Reg}(S)$ should be used to express the leading value of $L_{S,p}$ for this specific choice of $a_T$ and $a_T^*$ (see Section 5 for more details). However, it is reasonable to expect alternative choices of coefficients $b_T$ and $b_T'$ to be related to other types of regulators having formal properties different from those of Mazur–Tate regulators. Finally, observe that the results for $L_{S,p}$ proved in this paper still hold for any choice of $b_T$ and $b_T'$; see Remarks 4.1 and 4.2 below.

4.2. Results on the order of vanishing. Recall that $I_{G_S}$ and $I_{\Gamma_S}$ are the augmentation ideals of $\mathcal{O}_p[G_S]$ and $\mathcal{O}_p[\Gamma_S]$, respectively. The powers of $I_{G_S}$ define a decreasing filtration
\begin{equation}
\mathcal{O}_p[G_S] = I_{G_S}^0 \supset I_{G_S}^1 \supset I_{G_S}^2 \supset \cdots \supset I_{G_S}^\rho \supset \cdots
\end{equation}
on $\mathcal{O}_p[G_S]$. On the other hand, since the $\mathcal{O}_p$-module $\Lambda_p(K_S)$ is not in general torsion-free, we cannot expect tensorization of the sequence (62) by $\Lambda_p(K_S)$ over $\mathcal{O}_p$ to yield a filtration on $\Lambda_p(K_S) \otimes \mathcal{O}_p \mathcal{O}_p[G_S]$. In light of this, when we write that an element $\theta$ of $\Lambda_p(K_S) \otimes \mathcal{O}_p \mathcal{O}_p[G_S]$ belongs to $\Lambda_p(K_S) \otimes \mathcal{O}_p I_{G_S}^\rho$, we really mean that $\theta$ belongs to the natural image of the $\mathcal{O}_p$-module $\Lambda_p(K_S) \otimes \mathcal{O}_p I_{G_S}^\rho$ inside $\Lambda_p(K_S) \otimes \mathcal{O}_p \mathcal{O}_p[G_S]$.

Definition 4.2. Let $\tau \in \mathbb{N}$. An element $\theta \in \Lambda_p(K_S) \otimes \mathcal{O}_p \mathcal{O}_p[G_S]$ is said to vanish to order at least $\tau$ if $\theta \in \Lambda_p(K_S) \otimes \mathcal{O}_p I_{G_S}^\tau$.

Analogous definitions and conventions apply to $\mathcal{O}_p[\Gamma_S]$ and $I_{\Gamma_S}$ and, below, with $\Lambda_p(K_S)^{\otimes 2}$ in place of $\Lambda_p(K_S)$.

Theorem 4.3. If $\rho_p \leq p$ then $\theta_{S,p} \in \Lambda_p(K_S) \otimes \mathcal{O}_p I_{G_S}^{\rho_p}$.\[\text{\textit{Q.E.D.}}\]
Proof. Let $D_\kappa$ be a derivative with $\text{ord}(D_\kappa) < \rho_\theta$, $\text{supp}(D_\kappa) = S$ and $\text{cond}(D_\kappa) | S$. Set $S' := \text{cond}(D_\kappa)$ and write $D_\kappa = D_{\kappa'} \cdot D_{\kappa''}$ where the derivative $D_{\kappa'}$ satisfies $\text{supp}(D_{\kappa'}) = \text{cond}(D_{\kappa'}) = S'$ and the derivative $D_{\kappa''}$ has order 0 and support in $S/S'$ (so $D_{\kappa''}$ is nothing other than the norm operator from $G_S$ to $G_{S'}$). Part (1) of Proposition 3.3 combined with the relation \[ \sum_{\ell | (S/S')} a_\ell/\ell^{k/2-1} \] between Galois trace, restriction and corestriction map shows that
\[ D_\kappa(y_{S,p}) = \text{res}_{K_{S'}/K_S}(D_{\kappa'}(y_{S',p})) \cdot \prod_{\ell | (S/S')} a_\ell/\ell^{k/2-1} \] where $\text{res}_{K_{S'}/K_S}$ is the restriction from $H^1(K_{S'}, A_p)$ to $H^1(K_S, A_p)$. Let $p^m = \eta(\kappa)$ denote the highest power of $p$ dividing the orders of the groups $G_\ell$ with $\ell | S$. By definition, all primes dividing $S$ belong to $S_{p^m}$. Since $\rho_p \leq r_{p,m}$ by Lemma 3.4 we have $\text{ord}(D_\kappa) < r_{p,m}$. Therefore the assumptions of Theorem 3.3 are satisfied and then
\[ D_{\kappa'}(y_{S',p}) \equiv 0 \pmod{p^m}. \] Combining (63) and (64), we see that if $\text{ord}(D_\kappa) < \rho_\theta$ then $\eta(\kappa) | \text{ord}(D_\kappa(y_{S,p}))$. The result follows from the divisibility criterion in [4.3.2] which we can apply thanks to the condition $\rho_p \leq p$. □

Corollary 4.4. $\zeta_{S,p}, \zeta_{S,p}^* \in \Lambda_p(K_S) \otimes_{O_p} I_{G_S}^{p}$. Proof. The element $\zeta_{S,p}$ is the image of $\theta_{S,p}$ via the endomorphism of $\Lambda(K_S) \otimes I_{G_S}^{p}$ defined by $x \otimes i \mapsto (N_S(x)) \otimes i$. Since the Abel–Jacobi map commutes with Galois actions, it follows from Theorem 4.3 that $\zeta_{S,p}$ belongs to $\Lambda(K_S) \otimes I_{G_S}^{p}$. Applying the main involution, one obtains that $\zeta_{S,p}^*$ belongs to $\Lambda_p(K_S) \otimes I_{G_S}^{p}$ as well. □

Corollary 4.5. $L_{S,p} \in \Lambda_p(K_S) \otimes_{O_p} I_{G_S}^{2p}$. Proof. Since $L_{S,p}$ is a linear combination with coefficients in $O_p[\Gamma_S]$ of the elements $\zeta_{T,p}$ and $\zeta_{T,p}^*$ for $T | S$, the result is a consequence of Corollary 4.4 applied to these elements. □

Remark 4.6. More generally, the result of Corollary 4.5 is valid (with the same proof) for any linear combination with coefficients in $O_p[\Gamma_S]$ of the elements $\zeta_{T,p}$ and $\zeta_{T,p}^*$ with $T | S$. See Remark 4.1 for a detailed discussion of our specific choice of coefficients for $L_{S,p}$.

4.3. Results on the leading terms. We study, in some particular cases, the reductions modulo $p$ of the leading terms of $\zeta_{S,p}$ and $L_{S,p}$. Here $S$ is a square-free product of primes in $S_p$ and $\rho_p < p$.

We first consider the leading term $\tilde{\theta}_{S,p}$ of $\theta_{S,p}$, which is defined to be the image of $\theta_{S,p}$ in $\Lambda_p(K_S) \otimes_{O_p} (I_{G_S}^{p}/I_{G_S}^{p+1})$. By Theorem 4.3 there is a congruence
\[ \tilde{\theta}_{S,p} \equiv \sum_{\kappa} D_{\kappa}(y_{S,p}) \otimes (\sigma_1 - 1)^{k_1} \cdots (\sigma_t - 1)^{k_2} \pmod{p} \] where the sum is over all the $\kappa$ with $\text{ord}(\kappa) = \rho_\theta$. Denote by
\[ D_{\kappa}^{(p)}(y_{S,p}) \in \Lambda_p(K_S)/p\Lambda_p(K_S) \] the reduction modulo $p$ of $D_{\kappa}(y_{S,p})$ for $\text{ord}(\kappa) = \rho_\theta$.

Lemma 4.7. $D_{\kappa}^{(p)}(y_{S,p}) \in (\Lambda_p(K_S)/p\Lambda_p(K_S))^{G_S}$. Proof. Combine Theorem 4.3 and formula (24), for which the condition $\rho_p < p$ is needed. □

Recall that $N_S \in \mathbb{Z}[\Gamma_S]$ is a lift of the norm operator in $\mathbb{Z}[\Gamma_1]$.

Lemma 4.8. $D_{\kappa}^{(p)}(N_S(y_{S,p})) \in (\Lambda_p(K_S)/p\Lambda_p(K_S))^{G_S}$. Proof. Immediate from Lemma 4.7. □
By (15), there is an injection \( \Lambda_p(K)/p\Lambda_p(K) \hookrightarrow H_1^1(K, W_p[p]) \). Define the p-part \( \Pi_p(f/K) \) of the Shafarevich–Tate group of \( f \) over \( K \) as the cokernel of this map, so that there is a short exact sequence

\[
0 \rightarrow \Lambda_p(K)/p\Lambda_p(K) \rightarrow H_1^1(K, W_p[p]) \rightarrow \Pi_p(f/K) \rightarrow 0.
\]

See [35, p. 118] for a slightly different definition of \( \Pi_p(f/K) \).

**Proposition 4.9.** Suppose that \( |\rho_p^+ - \rho_p^-| = 1 \) and let \( D_\kappa \) have order \( \rho_p \) and support \( S \). If \( D_\kappa(y_{S,p}) \neq 0 \) (mod \( p \)) then

1. \( \Pi_p(f/K) = 0 \);
2. with \( A(S) \) defined as in (15), the natural map

\[
H_1^1(K, W_p[p]) \rightarrow A(S)
\]

is surjective.

**Proof.** We first observe that, by definition, one has

\[
(66) \quad 2\rho_p = \dim_{F_p}(X_p(K)) - 1.
\]

Proposition 3.30 shows that

\[
(67) \quad \rho_p \geq r_p(H^1_{f,S}(K, W_p[p^m])^{\kappa}) + r_p(A(S)^{\kappa}) \geq r_p(H^1_1(K, W_p[p^m])^{\kappa}),
\]

while Corollary 3.31 implies that

\[
(68) \quad \rho_p \geq r_p(H^1_{f,S}(K, W_p[p^m])^{-\kappa}) + r_p(A(S)^{-\kappa}) - 1 \geq r_p(H^1_1(K, W_p[p^m])^{-\kappa}) - 1
\]

for the last inequalities in the above chains, see the proof of Corollary 3.32. Since

\[
(69) \quad r_p(H^1_1(K, W_p[p^m])) \geq r_p((\Lambda_p(K)/p\Lambda_p(K))^{\kappa}) \geq \rho_p^+,
\]

we obtain the inequalities \( \rho_p \geq \rho_p^+ \) and \( \rho_p \geq \rho_p^{-\kappa} - 1 \). Therefore we have the inequality

\[
(70) \quad 2\rho_p \geq \dim_{F_p}(X_p(K)) - 1.
\]

Comparing (66) and (70), we conclude that all the above inequalities are, in fact, equalities; in particular, the first inequality in (69) is an equality, from which (1) follows immediately by definition of \( \Pi_p(f/K) \). Furthermore, the second inequalities in (67) and (68) are equalities, and then

\[
r_p(H^1_1(K, W_p[p^m])) = r_p(H^1_{f,S}(K, W_p[p^m])) + r_p(A(S)).
\]

Comparing this equality with the definition of \( H^1_{f,S}(K, W_p[p^m]) \) in (68) proves (2). \( \square \)

**Proposition 4.10.** If \( |\rho_p^+ - \rho_p^-| = 1 \) and \( \text{ord}(\kappa) = \rho_p \) then \( D_\kappa^{(p)}(N_{S_{y(S)}}) \) lies in the image of \( \Lambda_p(K)/p\Lambda_p(K) \).

**Proof.** By (15), there is an injective map

\[
(71) \quad \Lambda_p(K)/p\Lambda_p(K) \hookrightarrow H^1_1(K, W_p[p]) \subset H^1_1(K, W_p[p]).
\]

Recall that restriction gives an isomorphism \( H^1_1(K, W_p[p]) \cong H^1_1(K_{S,W_p[p]^*}) \) and that \( D_\kappa^{(p)}(N_{S_{y(S)}}) \) belongs to \( (\Lambda_p(K_S)/p\Lambda_p(K_S))^{\Gamma_S} \) by Lemma 4.8. In light of these facts and the \( \Gamma_S \)-equivariance of the injection (71), write \( d \) for the image of \( D_\kappa^{(p)}(N_{S_{y(S)}}) \) in \( H^1_1(K, W_p[p]) \).

We first show that \( d \in H^1_1(K, W_p[p]) \). By an argument similar to those in Propositions 3.15 and 3.16 one can check that the restriction of \( d \) at all places \( v \mid S \) is finite. There is a map

\[
(72) \quad \bigoplus_{v \mid S} H^1_{sin}(K_v, W_p[p]) \rightarrow H^1_1(K, W_p[p])^*.
\]
Corollary 4.12. Fix a square-free product $S$ of primes in $S_p$. 

1. The image $\mathcal{L}_{S_p}^{(p)}$ of $\mathcal{L}_{S_p}$ in 

$$(\Lambda_p(K_S)^{\otimes 2}/p\Lambda_p(K_S)^{\otimes 2}) \otimes_{\mathcal{O}_p} (I_p^{2p_\alpha}/I_p^{2p_\alpha+1})$$

belongs to the image of 

$$(\Lambda_p(K_S)^{\otimes 2}/p\Lambda_p(K_S)^{\otimes 2})^\Gamma_S \otimes_{\mathcal{O}_p} (I_p^{2p_\alpha}/I_p^{2p_\alpha+1})^\Gamma_S.$$
(2) If $|\rho^+_p - \rho^-_p| = 1$ then $\tilde{L}^{(p)}_{S,p}$ belongs to the image of $$(\Lambda_p(K)^{\otimes 2}/p\Lambda_p(K)^{\otimes 2}) \otimes_{O_p}(I_{T,S}^{2p}/I_{T,S}^{2p+1}).$$

(3) Assume that $\mathfrak{III}_p(f/K)$ is finite. If $|\rho^+_p - \rho^-_p| = 1$ and $p$ divides $|\mathfrak{III}_p(f/K)| \cdot |J(S)|$ then $\tilde{L}^{(p)}_{S,p} = 0.$

Proof. The term $L_{S,p}$ is an $O_p[\Gamma_S]$-linear combination of the elements $\zeta_{T,p}$ and $\zeta^*_{T,p}$ for $T \mid S,$ and the result is obtained by applying Theorem 4.11 to each of them. \hfill \square

Remark 4.13. In parallel with Remark 4.6 we observe that the results of Corollary 4.12 hold more generally for any $O_p[\Gamma_S]$-linear combination of the elements $\zeta_{T,p}$ and $\zeta^*_{T,p}$ for $T \mid S.$

4.4. Galois module structure of Heegner cycles. Fix a prime number $\ell \in S_p.$ Define $\mathcal{H}(K_\ell)$ to be the $O_p[G_\ell]$-module generated by $y_{\ell,p}$ inside $\Lambda_p(K_\ell)$ and denote by $\mathcal{H}_p(K_\ell)$ the $\mathbb{F}_p$-subspace $\mathcal{H}(K_\ell)/p\mathcal{H}(K_\ell)$ of $\Lambda_p(K_\ell)/p\Lambda_p(K_\ell).$ Finally, recall from \S 3.11 that $r_p = r_{p,1}.$

Theorem 4.14. \ $\dim_{\mathbb{F}_p}(\mathcal{H}_p(K_\ell)) \leq \ell + 1 - r_p.$

Proof. By (3.4.4) an $O_p$-basis of $\mathcal{H}(K_\ell)$ is given by $\{D^i_\ell(y_{\ell,p}) \mid i = 0, \ldots, \ell\}.$ Theorem 3.33 shows then that $D^i_\ell(y_{\ell,p}) \equiv 0 \pmod{p}$ if $k < r_p,$ and hence at most $\ell + 1 - r_p$ elements of the $O_p$-basis of $\mathcal{H}(K_\ell)$ under consideration are non-zero. \hfill \square

5. Regulators

In this final section we propose an axiomatic construction of regulators in our context, generalizing those introduced by Mazur and Tate in [32] and [33] and used in Darmon’s work [18]. We believe that this picture can be made unconditional by adopting the point of view of Nekovář ([36]). We also observe that a cohomological approach to Mazur–Tate regulators, along the lines of the theory developed by Bertolini and Darmon in [2] and [3], is certainly possible, at least in some special situations: we plan to come back to these issues in a future project.

Let $K$ be an imaginary quadratic field of discriminant coprime to $Np$ and let $S > 1$ be a square-free product of primes that are inert in $K,$ then define

\begin{equation}
\Lambda_{p,S}(K) := \ker\left(\Lambda_p(K) \longrightarrow \bigoplus_{\lambda \mid S} H^1_{\lambda}(K_\lambda, A_p)\right)
\end{equation}

where the map is induced by $\mathbb{L}$ via localizations. Finally, recall the maps $\mu_{S,T}$ introduced in \S 4.1, which are defined for integers $T \mid S.$ Our starting point is the following

Assumption 5.1. There exists a bilinear pairing

$$\langle \cdot, \cdot \rangle_S : \Lambda_p(K) \times \Lambda_{p,S}(K) \longrightarrow I_{T,S}/I_{T,S}^2$$

satisfying the compatibility condition

$$\mu_{S,T} \circ \langle \cdot, \cdot \rangle_S = \langle \cdot, \cdot \rangle_T$$

for all $T \mid S.$

As in [18], we use this pairing to construct a regulator map. Let $\ell$ be a prime number dividing $S$ and, as before, let $\lambda$ be the unique prime of $K$ above $\ell,$ then write $F_\lambda$ for the arithmetic Frobenius in $\text{Gal}(\mathbb{Q}_\ell^p/K_\lambda).$ Recall from [24] that $V_\ell = A_p \otimes_{O_p} F_\ell.$ We have

$$\det(F_{\ell} \pm 1 | V_\ell) = \ell + 1 + \frac{a_\ell}{\ell^{2} - 1}.$$
which are non-zero thanks to the Weil bounds, hence
\[
\det(F_\ell - 1 | V_p) = \det(F_\ell + 1 | V_p) \cdot \det(F_\ell - 1 | V_p)
\]
\[
= (\ell + 1)^2 - \frac{a_2^2}{2\ell k - 2} \neq 0.
\]
Then [12, Theorem 4.1, (i)] implies that \(H_1^f(K_\Lambda, A_p)\) is finite, so the codomain of the map in (73) is finite and the ranks of \(\Lambda_{p,S}(K)\) and \(\Lambda_p(K)\) over \(O_p\) are equal. As in (21), this common rank will be denoted by \(\tilde{\rho}_p\). Fix finite index subgroups \(A \subset \Lambda_p(K)\) and \(B \subset \Lambda_{p,S}(K)\) that are \(O_p\)-free and choose \(O_p\)-bases \(\{P_1, \ldots, P_{\tilde{\rho}_p}\}\) and \(\{Q_1, \ldots, Q_{\tilde{\rho}_p}\}\) of \(A\) and \(B\), respectively. Form the matrix
\[
R(A, B) := ((P_i, Q_j)_S)_{i,j=1}^{\tilde{\rho}_p}
\]
with entries in \(I_{\Gamma_S}/I_{\Gamma_S}^2\) and let \(R_{i,j}(A, B)\) be the \((i, j)\)-minor of \(R(A, B)\). Consider the element
\[
\text{Reg}(A, B) := \sum_{i,j=1}^{\tilde{\rho}_p} (-1)^{i+j}(P_i \otimes Q_j) \otimes \det(R_{i,j}(A, B)) \in \Lambda_p(K)^{\otimes 2} \otimes (I_{\Gamma_S}^\rho - 1 / I_{\Gamma_S}^\rho)
\]
and define the regulator term \(\text{Reg}(S)\) as
\[
\text{Reg}(S) := \text{Reg}(A, B)/([\Lambda_p(K) : A] \cdot [\Lambda_{p,S}(K) : B]).
\]
This is independent of the choice of \(A\) and \(B\).

Let \(B(S)\) denote the cokernel of the map in (73), so that there is an exact sequence
\[
0 \to \Lambda_{p,S}(K) \to \Lambda_p(K) \to \bigoplus_{\lambda(S)} H_1^f(K_\Lambda, A_p) \to B(S) \to 0.
\]

The analogue of Darmon’s conjecture [18, Conjecture 2.3] in the present context amounts to the following

**Question 5.2.** Suppose that \(\text{III}_p(f/K)\) is finite. Is there a pairing as in Assumption [5.1] such that the following conditions are satisfied?

1. \(L_{S,p} \in \Lambda(K_S)^{\otimes 2} \otimes I_{\Gamma_S}^{\rho_p - 1}\).
2. The leading coefficient \(\tilde{L}_{S,p}\) of \(L_{S,p}\) in \(\Lambda(K_S)^{\otimes 2} \otimes (I_{\Gamma_S}^{\rho_p - 1} / I_{\Gamma_S}^{\rho_p})\) belongs to the image of the canonical map
\[
\Lambda(K)^{\otimes 2} \otimes (I_{\Gamma_S}^{\rho_p - 1} / I_{\Gamma_S}^{\rho_p}) \to \Lambda(K_S)^{\otimes 2} \otimes (I_{\Gamma_S}^{\rho_p - 1} / I_{\Gamma_S}^{\rho_p}).
\]
3. There exists \(c(f) \in O_p\) depending only on \(f\) such that
\[
\tilde{L}_{S,p} = c(f) \cdot \text{III}_p(f/K) \cdot |B(S)| \cdot \text{Reg}(S).
\]

Here \(\text{Reg}(S)\) denotes also the image of \(\text{Reg}(S)\) via the map in (74), by an abuse of notation.

A few remarks are in order here. First of all, parts (1) and (2) of Question 5.2 do not depend on \(\text{Reg}(S)\), so they can be formulated independently of Assumption [5.1]. Moreover, thanks to the compatibility condition in Assumption [5.1] one can show that
\[
\mu_{S,T}(|B(T)| \cdot \text{Reg}(T)) = |B(S)| \cdot \text{Reg}(S) \cdot \prod_{\ell(S/T)} (1 + \ell - a_\ell/\ell^{k/2} - 1) \cdot (1 + \ell + a_\ell/\ell^{k/2} - 1)
\]
whenever \(T \mid S\). Comparing with [61], one sees that (1), (2) and (3) above are all compatible with the map \(\mu_{S,T}\) when \(T \mid S\). Actually, as in [13], it is compatibility relation that suggests the definition of \(L_{S,p}\) given above. However, different regulators might be attached to different choices of the coefficients \(b_T\) and \(b_T'\), as discussed in Remark [13]. The choice of correct regulators and \(\mathcal{L}\)-elements is an open problem, although we believe that, in light of [61] and the fact that the relation in Assumption [5.1] is very natural, our definition of \(L_{S,p}\) is
in some sense the “standard” one. Furthermore, since $2\rho_p \geq \tilde{\rho}_p - 1$ with equality holding if and only if $|\rho_p^+ - \tilde{\rho}_p| = 1$, we can state the following partial results.

1. Condition (1) in Question 5.2 is implied by Corollary 4.5 and is equivalent to it if $|\rho_p^+ - \tilde{\rho}_p| = 1$.

2. If $|\rho_p^+ - \tilde{\rho}_p| = 1$ and all the prime factors of $S$ belong to $S_p$ then a mod $p$ version of (2) in Question 5.2 is given in part (2) of Corollary 4.12.

3. Suppose that $|\rho_p^+ - \tilde{\rho}_p| = 1$ and all the prime factors of $S$ belong to $S_p$. In this case, if $p$ divides $|\Pi_p(f/K)| \cdot |B(S)|$ then $p$ divides $\tilde{L}_{S,S_p}$ as well. This is a simple consequence of part (3) of Corollary 4.12.

Let us finally observe that if $|\rho_p^+ - \tilde{\rho}_p| > 1$ then (1) predicts more than what is proved in Corollary 4.5 and the question about the leading term of $\tilde{L}_{S,S_p}$ might be addressed, at least in some special cases, by means of a suitable theory of generalized regulators as in [2] and [3].
