Abstract

Background: Our previous research showed that icariin (1) and its phosphorylated structural modification (2) improved the survival and attenuated oxidative stress and liver dysfunction induced by duck virus hepatitis. In this paper, we were one step closer to determine the structure of phosphorylation icariin (2) by the FT-IR, HRESIMS and $^{13}$CNMR. Anti-DHAV activities of 1 and 2 were compared in duck embryonic hepatocytes (DEHs) cultured in vitro and by artificial infection method in vivo. Additionally, the antiviral mechanisms of replication/release in vitro and the DHAV gene expression in vivo of 1 and 2 were analyzed.

Results: Compound 2’s molecular formula was C$_{33}$H$_{42}$O$_{18}$P. The results indicated that 1 and 2 effectively resisted DHAV invading DEHs, that they decreased the mortality of ducklings challenged with DHAV, and that 2 performed more effectively. 1 and 2 performed evenly on DHAV release; however, 2 restrained virus replication far more effectively. Since the anti-DHAV mechanisms of 1 and 2 in vitro probably involve suppression of replication and release, 2’s better performance in anti-DHAV may result from its far more effectively inhibiting virus replication.

Conclusions: The compound 2’s chemical structure was defined as 8-prenylkaempferol-4’-methylether-3-rhamnosyl-7-(6''-phosphate)-glycoside. 1 and 2 exhibited anti-virus activity on DHAV. Our results suggest that 1 and 2 might become an anti-virus plant material candidate.

Keywords: Icariin, Phosphorylated structural modification, HRESIMS, NMR, Duck hepatitis virus A

Background

Duck viral hepatitis (DVH) is an acute, contagious, highly fatal disease of young ducklings, which was first described on Long Island, NY, USA, in 1949 [1]. The causative agent, duck hepatitis virus (DHV), historically belongs to the family Picornaviridae and is divided into three serotypes (DHV-1, 2, and 3). DHV-1 is the most widely distributed and the most virulent one among the three types of DHV [2]. Recently, sequence analysis of duck hepatitis virus type 1 led to its classification as the only member of a new genus, Avihepatovirus, of the family Picornaviridae, so the DHV-1 was renamed to DHAV [3]. DHAV predominantly infects young ducklings aged less than three weeks. Clinically, the disease is acute, rapidly spreading, with a shorter course and high mortality rate. Meanwhile, the DVH is an attractive research model of human hepatitis, with great potentialities in both human and veterinary medicine [4]. In the absence of effective anti-DHAV drugs, immunizing ducks or young ducklings with attenuated DHAV vaccines is the primary approach to disease control. However, vaccines are not totally effective and any clinical manifestation may cause potentially irreparable damage.

Several types of flavonoids including those from epimedium and propolis as well as prescriptions of flavonoids ingredients showed significant resistance to Newcastle disease, infectious bursal disease and other viral diseases in our previous experiments [5], although the underlying mechanisms were not researched in detail. Epimedium is a well-known traditional herbal medicine in China used for centuries to invigorate kidney and strengthen kidney – yang. Contemporary pharmacologic experiments indicate that Epimedium flavone has anti-aging, anti-tumor and...
anti-osteoporosis activities [6–9]. Icariin (C33H40O15s, 1, Fig. 1.) is the main effective component of Epimedium brevicornum Maxim [10]. 1 exhibits many biological activities and pharmacological effects, including antioxidant, anti-inflammatory, anti-tumor [11]. Previous research showed that 1 enhanced the cellular and humoral immunity in mice, and increased the phagocytic activity of macrophages in immune-depression mouse models caused by massive doses of hydrocortisone and hydroxyurea [12]. Therefore, we choose the 1 as the study object.

Molecular modification of flavonoids and polysaccharide became an important research field along with the increasing pursuit about manifold biological activities of modified. Many studies confirmed that the biological activities of the Chinese herbal ingredients could be improved by the chemical method (sulfated, phosphated, selenylation). In our previous published work, we found that the compound 1 and phosphorylated icariin (C33H42O18P, 2, Fig. 1) could alleviate the oxidative stress and liver injury in ducklings caused by DHAV. These outcomes were better in ducklings treated with 2 than in those treated by 1. In clinical trials, compared with 1, 2 could significantly improve survival rate [13]. This is the most important to the meaning of the actual production application. So we believe that this novel structure resulted in the difference. But between the 1 and 2, their antioxidant effect was similar. It’s suggested that there may be another resistance mechanisms to anti-DHAV infection. To further study its resistance mechanism, we hold the opinion that it is essential to confirm the structure of 2 and study the effect of drug for viral multiplication process. Above on, we determined the chemical structure of 2 by the FT-IR, HRESIMS and 13C NMR and the compound 1 and compound 2 antiviral efficacies against DHAV in vivo and in vitro were investigated.

Methods
Reagents and virus
Dulbecco’s modified eagle medium (DMEM) (Gibco) supplemented with streptomycin 100 IU/mL, penicillin 100 IU/mL, 10% fetal bovine serum and glutamine 0.75 mg/mL was used as the nutritive medium. The fetal bovine concentration of the maintain medium (MM) was reduced to 1 %. Dulbecco’s Hanks Balanced Salt Solution (D-Hank’s) was used for washing the embryo. The pH of D-Hank’s, DMEM and MM solutions was adjusted to 7.4 with 5.6 % NaHCO3 and stored at 4 °C. Trypsin (Amresco) was dissolved with D-Hank’s up to 0.2 %. The 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT, Amresco) was dissolved to 5 mg/mL with phosphate-buffered saline (PBS), filtered through a 0.22 μm syringe filter, and stored at 4 °C in dark bottles. Other chemicals used in the experiment were analytical grade. RNAiso Plus Reagent (Lot no. 9108), PrimeScript RT Master Mix Kit (Lot no. RR036A) and SYBR Premix Ex Taq (Tli RNaseH Plus) Kit (Lot no. RR036A) were bought from Takara. Fluorescein isothiocyanate-labeled rabbit anti-DHAV (Lot no. orb8860) was bought from biorbyt. DHAV (LD505 × 10−3) strain LQ2 used in the challenge experiments was supplied by the Shandong Institute of Poultry (Shandong, China, −70 °C storage). All other chemicals are from standard commercial suppliers, having analytical grade quality.

Preparation of icariin
Compound 1 was purified repeatedly from the extract of Epimedium segittatum by column chromatography (CC) and prepared HPLC. The dried leaves (5 kg) of this plant was extracted three times with 85 % (v/v) EtOH under refluxed (40 L each time for 2 h). The combined extract were concentrated under reduced pressure to give a residue (0.3 kg), which was further partitioned with petrol-ether (PE, boiling point 60–90 °C, 4 L), ethyl acetate (EtOAc, 4 L) and n-BuOH (4 L), successively. The EtOAc fraction (38 g) was subjected to a silica gel CC (400 g, 100–200 mesh, 600 × 40 mm) eluted with a step gradient of CH2Cl2-MeOH-H2O (90:1:0.1, 20:1:0.1, 10:1:0.1, 5:1:0.1, v/v, 3 L each step gradient) to give five sub-fractions (E1-E5, 2.2 g, 3.1 g, 3.8 g, 4.6 g, 8.9 g, respectively). E4 (0.2 g) was then purified by Sephadex LH-20 CC (1200 × 24 mm) with MeOH-H2O (2:1 to 1:1, v/v, 1.2 L each gradient) to obtain crude flavonoids (0.12 g). The crude flavonoids were further separated by prepared HPLC (column Kromasil 250 × 10 mm, 5 μm, CH3CN-H2O, 23:77, v/v, 1.6 L) and recrystallized

![Fig. 1](Image) Structure of icariin (1) and 6''-phosphate icariin (2)
with water repeatedly to yield Icariin (83 mg), whose purity quotient was over 98%.

HPLC conditions: YMC-Triart C18, (5 μm, 4.6 × 250 mm; YMC), solvent system: A - MeOH, B - H₂O, C - MeCN, D - 0.2 % H₃PO₄; flow rate: 1 mL/min; injection volume: 20 μL; Sample concentration: 10 mg/mL in MeOH. DAD conditions: 270 nm.

HRESIMS conditions: positive ion mode; scan range: 500–4000 m/z; source temperature: 300 °C; ion spray voltage: 4 kV.

**Preparation of phosphorylated icariin**

2.5 g sodium trimetaphosphate and 1.0 g sodium tripolyphosphate were mixed in 50 mL of distilled water, with stirring. Compound 1 (500 mg) was dissolved in 100 mL of distilled water and added to the sodium trimetaphosphate-sodium tripolyphosphate reagent, and stirred in a water bath at 70 °C for 6 h at pH 9. The resulting solution was dialyzed, purified by ODS column chromatography and preparative HPLC (YMC, 4 μm, 150 mm × 20 mm, MeCN/H₂O, 35:65), UV detection at 210 nm, and lyophilized to yield compound 2.

Icariin (1): yellow amorphous powder; FT-IR (KBr) ν_{max} = 3396,1651,1600,1500,1453 cm⁻¹;¹³C NMR (DMSO-d₆, 100 MHz) data in Table 1; HRESIMS m/z 676.7400 [M + H]⁺ (calcd for C₃₃ H₄₄ O₁₁₆, 677.2396).

Phosphorylated icariin (2): yellow amorphous powder; FT-IR(KBr) ν_{max}=3384,1652,1610,1430,1504,1148,919 cm⁻¹;¹³C NMR (DMSO-d₆, 100 MHz) data in Table 1; HRESIMS m/z 757.2034 [M + H]⁺ (calcd for C₃₃ H₄₂ O₁₁₈ P, 757.2072).

**Animal experiments**

Animal experiments conformed to the Guide for the Care and Use of Laboratory Animals published by the US National Institutes of Health (NIH Publication, Eighth edition, 2011) and were approved by the Nanjing Agricultural University Animal Care Committee (No. 20130093, 2013). To ameliorate suffering, animals which were not expected to survive were humanely euthanized. All steps were complied with AVMA Guidelines for the Euthanasia of Animals (2013 Edition).

One-day-old cherry valley ducks were purchased from Nanjing Tangquan Poultry Farm (Nanjing, China). Ducks were housed in wire cages (60 cm × 100 cm) in air conditioned rooms at 37 °C with lights on for 24 h before the study. The temperature was gradually reduced to room temperature and 12-h light/12-h dark phases, which were kept constant for the remainder of the study. Ducks were fed a commercial starter diet provided by the feed factory of Jiangsu Academy of Agricultural Science (Nanjing, China). Three-day-old cherry valley ducks (n = 180) were randomly divided into four groups: 1-treated group, 2-treated group, virus control (VC) group, and a blank control (BC) group (separately reared). Ducklings allocated to the 1, 2 and VC groups were intramuscularly injected with 0.2 mL of DHAV (20 × LD₅₀) per duckling. Ducklings allocated to the 1 or 2 groups were given aqueous 1 or 2 at the dosage of 31.25 mg/kg (net concentration) of per duckling, SID, for 3 days starting on the same day as DHAV injection. Before used, 1 was prepared with 3 % ethanol dissolved, and added a co-solvent 0.5 % Tween 80. In order to ensure the consistency of test, we added the equal amount of ethanol and Tween 80 in the drinking in the 2, VC and BC groups. The dissolution characteristic of 2 is instant into the water. Blood samples were taken from five ducklings in each group at the 4th, the 8th, and

¹The chemical shifts (δ) are expressed in parts per million. ²Data recorded in dimethyl sulfoxide-d₆.
the 54th h after injecting DHAV. Half of each blood sample was treated with heparin for anticoagulation and the remainder was left to coagulate. Number of ducks which had been taken blood samples needed to be eliminated (n = 15 per group).

Preparation of duck embryonic hepatocytes (DEHs) and DHAV
Livers were removed from 14-to-16-day-old duck embryos in sterile conditions followed by gallbladder evisceration [14]. The livers were washed three times with D-Hank's. The tissue was minced with eye scissors and washed three times with D-Hank's. Liver tissue was digested with a solution of 0.2 % trypsin at 37 °C for 4 to 6 min. As soon as the trypsin was completely absorbed, the tissue was rinsed three times with D-Hank's and an appropriate amount of DMEM growth medium was added. The seeding cell density was controlled within the range of 0.8 × 10^6-1.2 × 10^6 cell/mL, incubated at 37 °C in a humid atmosphere of 5 % CO₂, the growth medium replaced after 24 h [15]. DMEM was removed when the duck embryo hepatocytes grew into monolayer. The duck embryonic hepatocytes monolayer (DEHs) was washed with calcium and magnesium-free phosphate-buffered saline (CMF-PBS, pH 7.4) once, and left as standby until CMF-PBS was removed again. The DHAV used for challenge experiments and antiviral assays was supplied by the Shandong Institute of Poultry in China and proliferated by inoculating DEHs. The TCID_{50} of the virus liquid was 1 × 10^{-3} by Reed-Muench assay [16]. It was diluted into 5 × 10^{-2} (50 TCID_{50}) with MM and used for antiviral assays.

Antiviral activity in vitro
The maximum safe concentration of 1 was 250 μg/mL tested by preliminary experiment with MTT method while that of 2 was 1250 μg/mL. 1 was serially twofold diluted with MM from 250 μg/mL to 31.25 μg/mL, and 2 from 1250 μg/mL to 156.25 μg/mL, thus obtaining 4 concentrations each. 70 μL DHAV was added to each well of 96-well culture plate containing the DEHS monolayer. Meanwhile, cell control (CC) group and virus control (VC) group were set. The plate was cultured at 37 °C in a humid atmosphere of 5 % CO₂ for 2 h. The virus solution was removed and the monolayer was washed three times with D-Hank's. Subsequently, 70 μL dilution of test ingredient was added to test well using 5 wells per concentration. The plate was left at 37 °C in a humid atmosphere of 5 % CO₂ for 2 h. The virus solution was removed again. It was diluted into 5 × 10^{-2} (50 TCID_{50}) with MM and used for antiviral assays.

Quantitative analysis of blood DHAV
To monitor the blood virus contents in virusemia phases (the 4th h and the 8th h) and stable (the 54th h) phases of the disease, blood samples randomly taken from 5 feathers per group at the 4th h, the 8th h and the 54th h after challenged with virus were collected, treated with heparin anticoagulation and used for testing its virus nucleic acid contents. Real-time polymerase chain reaction (Real-time PCR) was employed in the quantitative analysis of DHAV gene expression at the 4th h, the 8th h and the 54th h in vivo [19].

Clinical effect
Mortality was calculated after all the young ducklings ceased to die using the equation: Mortality of each group (%) = Death in each group/effective samples in each group × 100 %, and the number of ducks providing blood samples needed to be eliminated (15 feathers per group).

Analysis of virus replication
400 μL DHAV was added into the 24-well culture plate containing a DEHS monolayer, while the CC and VC wells were reserved. The plate was incubated at 37 °C for 2 h in a humid atmosphere of 5 % CO₂, and the virus solution removed. The plate was washed 3 times with D-Hank's. Later, 400 μL dilution of test drug was added into the test wells, three wells in parallel, as the most effective antiviral concentration. The 24-well culture plate was incubated at 37 °C for 24 h in a humid atmosphere of 5 % CO₂ and the total RNA was extracted. Real-time PCR was used to analyze the extent of virus replication.

Analysis of virus release
400 μL DHAV was added into the 24-well culture plate containing monolayer DEHS, while the CC and VC wells were reserved. The plate was incubated at 37 °C for 2 h in a humid atmosphere of 5 % CO₂. The virus solution was removed and the plate was washed 3 times with D-Hank's. 400 μL dilution of test drug at the most effective antiviral concentration was then added into the test wells, three wells in parallel. The plate was continuously incubated at 37 °C in a humid atmosphere of 5 % CO₂ for 48 h. The supernatant of cells was centrifuged and the sediment was removed. 100 μL supernatant and 100 μL DEHS (0.8 × 10^6-1.2 × 10^6 cells/mL, as the internal reference) were mixed together and the total RNA was extracted. Finally real-time PCR was used to analyze the virus release content.

Primer design
The primers based on the complete genome of DHAV (ZJ strain; Genbank: EU841005) were designed using Primer Premier Software (version 5.0). The forward and reverse primers were 5’-GCCACCCCTTGGAGTGGTTTGT-3’.
(positions: 3336–3355) and 5’-TACCATTCACCTTCC TGCTT-3’ (positions: 3489–3510), respectively. Duck Beta-actin was selected as the control. The primers based on the complete coding sequence of Anas platyrhynchos beta-actin mRNA (Genbank: EF667345) were designed using Primer Software (version 5.0). The forward and reverse primers were 5’-CTTTCTTGGGTATGGAGTCCG-3’ (positions: 826–847) and 5’-TGATTTCTCATGCTGGT-3’ (positions: 995–1014), respectively.

Statistical analysis

$2^{\Delta \Delta CT}$ method was used to analyze relative gene expression data [20]. The data of $A_{570}$ value and relative gene expression value were expressed as the mean ± S.D.. Duncan’s multiple range tests were used to analyze the difference among groups with the software SPSS 20.0. $\chi^2$-test was used to analyze the difference between the mortality. Significant differences were considered as $p < 0.05$.

Results

Compound 1 was obtained as a yellow, amorphous powder. Its molecular formula (C$_{33}$H$_{42}$O$_{18}$P) was established on the basis of high-resolution electrospray ionization mass spectrometry (HRESIMS) (m/z 676.7400 [M + H]$^+$); calcd for C$_{33}$H$_{42}$O$_{18}$P, 677.2396, Fig. 2). The FT-IR spectrum exhibited characteristic absorptions for hydroxy (3396 cm$^{-1}$), carbonyl (1651 cm$^{-1}$), and aromatic (1600 and 1454 cm$^{-1}$) functionalities. It was consistent with the structure of icariin [21].

Compound 2 was obtained as a yellow, amorphous powder. Its molecular formula (C$_{33}$H$_{40}$O$_{15}$P$_{3}$) was established on the basis of $^{13}$C NMR and HRESIMS data (m/z 757.2034 [M + H]$^+$; calcd for C$_{33}$H$_{40}$O$_{15}$P$_{3}$, 757.2072, Fig. 2). The FT-IR spectrum exhibited characteristic absorptions for hydroxy (3384 cm$^{-1}$), carbonyl (1652 cm$^{-1}$), and aromatic (1610 and 1430 cm$^{-1}$) functionalities, it was similar to 1. Furthermore, 2 also displayed extra absorption peaks at 1160.61 and 918.15 cm$^{-1}$, corresponding to the phosphate group. The $^{13}$C NMR data (Table 1) of 2 were similar to those of 1, except for the the C-6’ (1 C-6’:$\delta_{C}$6.110; 2 C-6’:$\delta_{C}$7.017), it suggested that the phosphate group was located at C-6’, which instead of oxhydryl. Combined with FT-IR, HRESIMS and $^{13}$C NMR data, suggesting that compound 2 was also a phosphorylated derivative of 1 and the structure was defined as 8-prenykaempferol-4’-methyl ether-3-rhamnosyl-7-(6’-phosphate)-glycoside and given the name 6’-phosphate icariin.

Table 2 listed the $A_{570}$ values and virus inhibitory rate in the anti-DHAV activity test in DEHs. The $A_{570}$ values of the 1 group ranging from 62.5 µg/mL to 31.25 µg/mL, and the $A_{570}$ values of the 2 group ranging from 312.5 µg/mL to 156.25 µg/mL were significantly higher than that of the VC group. The $A_{570}$ value of the 2 at 156.25 µg/mL was also notably higher than that of the CC group, which indicated that 2 also promote cell growth. The virus inhibitory rates of 2 were higher than that of 1 at similar concentrations, with the highest one at 135.78 %, while the highest of 1 being 98.28 %.

The mortality of young ducklings in the BC, VC, 1, 2 groups was 0, 30, 24, 21 feathers. All ducklings in the BC group survived. After treatment with 1 and 2, the young ducklings challenged with DHAV no longer died after 72 h, while all of the ducklings in the VC group died on the 4th day. Both mortality of compound 1 (80 %) and compound 2 (70 %) were lower than that of the VC group (100 %), and compound 2 group’s mortality was significantly lower than that of the VC group.

A quantitative analysis of the DHAV gene expression in blood at the 4th, the 8th and the 54th h after injected with virus was illustrated in Fig. 3. No DHAV gene expression was found in the BC group. DHAV gene expression of the VC group in the 4th h after injected virus was set to 1 and that of the BC group was set to 0. The VC group dynamics indicated that the DHAV content first increased and then decreased in vivo of ducklings, with the pattern of the 1 and 2 groups similar to that of the VC group. The relative expressions of DHAV gene in blood of the 1 and 2 groups were lower than that of the VC group during the same period. Four hours after DHAV injection, the virus gene expressions in both the 1 and 2 groups were lower than that of the VC group. At the 8th hour after DHAV injection the virus contents of the 1 and 2 groups were lower than that of the VC group with significant difference. At the 54th h after DHAV injection the virus gene content of the 2 group was remarkably lower than that of the VC group.

The effect of 1 and 2 on replication of DHAV was illustrated in Fig. 4. No DHAV gene expression was found in the CC group. DHAV gene expression of the VC group in the twenty-fourth hour was set to 1. Relative DHAV gene expressions of 1 and 2 groups were 0.549 and 0.248; both were significantly lower than that of the VC group. Relative expression of 2 was significantly lower than that of 1.

The effect of 1 and 2 on the release of DHAV was illustrated in Fig. 5. No DHAV gene expression was found in the CC group. The DHAV gene expression of the VC group in the 48 h was set to 1 and that of the BC group was set to 0. Relative expressions of 1 and 2 were 0.476 and 0.575. And both were significantly lower than that of the VC group.

Discussion

Acid ions cannot only bind to virus or cell skin cation to inhibit viral invasion or replication, but also enhance the antiviral effect and water solubility of drugs [22]. This experiment sought for the optimal conditions for
phosphorylated modification of 1 and successfully introduced phosphate group. It still preserved the flavones’ basic chemical structure. The results showed that 2 had significantly better water solubility than 1 and was suitable for practical application. The higher the drug’s maximum concentration was, the safer it was inside the cell in vitro [23]. In the present experiment, the maximum tolerable dose of 2 (1250 μg/mL) was much higher than that of 1 (250 μg/mL). The results indicated that the cellular toxicity of 1 may be significantly reduced by phosphorylation.

The antiviral activity assays of 1 and 2 in vitro using MTT method indicated that higher A$_{570}$ values were associated with improved antiviral properties [24]. Virus inhibitory rates directly reflected the drug’s antiviral performance. Within a certain range, the A$_{570}$ values of 1 and 2 were significantly higher than that of the VC group; with some A$_{570}$ values of 2 even higher than the

**Table 2** A$_{570}$ values and virus inhibitory rate in DHAV test on DEHs

Fig. 2 HRESIMS spectrum of compound 1 and 2
CC group. Within the effective concentration range, the virus inhibitory rates of 2 and the maximum inhibitory rate were both higher than those of 1. The results suggested that both 2 and 1 in vitro possessed strong anti-DHAV function, with 2 stronger than 1.

In clinical trials, DHAV was infectious for young ducklings aged up to 3 weeks, particularly those less than 1-week-old, whose mortality rate was higher than 90 % [25]. Therefore, we selected 3-day-old young ducklings for this experiment taking into account the clinical significance. In this study, all ducklings in the BC group survived. After treatment with 1 and 2, the young ducklings challenged with DHAV no longer died after 72 h, while all of the ducklings in the VC group died on the 4th day. Mortalities of the 1 and 2 groups were both lower than that of the VC group, which proved that both 1 and 2 had anti-DHV effect. If focused on the mortality of the 2 group, we could...
find that it was significantly lower than that of the VC group, indicating its superior effect compared to 1. The results were consistent with the anti-DHAV invading cells, in vitro.

DHAV is classified in the family parvoviridae [26]. It completes a cycle of replication in 6–8 h, in vivo. In early phase of infection, humoral immunity to anti-DHAV is still not active. Instead, organisms mainly relied on the direct antivirus effects of the drug. A quantitative analysis of the DHAV gene expression in blood at the 4th, the 8th and the 54th h after injected with virus was illustrated in Fig. 3. Four hours after virus invasion, it was possible that virus still failed to complete replication. As the gene expressions of DHAV in the 1 and 2 groups were lower than that of VC group, no substantial differences between virus level in blood of the 1, 2 and VC groups was observed. At the 8th h, the virus had at least completed one replication cycle. The blood virus contents in the 1 and 2 groups were significantly lower than that of VC group, no substantial differences between virus level in blood of the 1, 2 and VC groups was observed. At the 8th h, the virus had at least completed one replication cycle. The blood virus contents in the 1 and 2 groups were significantly lower than that of VC group. In addition, since 2 was more potent, the 2 group blood virus content was lower than that of the 1 group. At the 54th h, with the activation of humoral immunity and increased cytokine levels, the levels of the 1, 2 and VC groups’ blood virus plummeted. The 1 and 2 groups’ blood virus contents were lower than that of the VC group and this is especially significant for the 2 group. The results were consistent with the death of the ducklings in the challenging experiment. We are submitting another article has reported that the contents of IFN-γ, IL-2 and IL-6 in the 1 and 2 groups were significantly higher than those in the VC group at the 54th h, which indicated that 1 and 2 could obviously improve immunomodulatory activity. It also demonstrated that the treatment of traditional Chinese medicine maybe more reflected in the balance of the internal systems, rather than directly inhibited or killed pathogenic microorganisms.

Previous studies established a solid basis for the molecular detection of DHAV using Real-time PCR [19]. RT-PCR with its higher specificity, less PCR contamination and higher automation has been widely applied in the field of diagnosis and detection of DHAV. During virus replication, the relative quantitative gene expressions of the 1 and 2 groups were significantly lower than that of the VC group (Fig. 4). The results suggested that 1 and 2 greatly inhibited the replication of DEHs in vitro, and that 2 outperformed 1. Lu et al. [22] also found that acid ions prevented virus from replicating inside cells. Acid ions of PO₄³⁻ introduced into 1 enhanced the inhibition of DHAV in vitro.

In virus release phase (Fig. 5), the relative quantitative gene expressions of the 1 and 2 groups were significantly lower than that of the VC group. Both had similar inhibitory effect on DHAV releasing DEHs in vitro. Therefore, based on the results of virus replication and release in vitro, both 1 and 2 had significant inhibitory function on virus activity, although the 2 was better due to its acidic groups. Due to direct inhibition of virus replication in the 1 and 2 groups, and consequent lowered blood viral content, the ducks were spared from possible harm and showed a decreased Mortality, especially true for the 2 group. The antiviral immune response stimulated by the 1 and 2 also helped in substantially reducing the damage due to DHAV. Additional studies to confirm our findings in vivo are required.

**Supporting information**

¹³C NMR of compound 1and compound 2.
Conclusions
The compound 2 was also a phosphorylated derivative of 1 and the structure was defined by FT-IR, HREIMS and $^{13}$C NMR. Compound 1 and 2 effectively resisted DHAV from invading DEHs in vitro, and had good therapeutic effects in young ducklings infected with DHAV. The mortality was significantly decreased and 2 showed better effect than 1, it showed that the novel structure was worth further research for application. The mechanism underlying the antiviral activity of 2 and 1 in vitro was probably mediated by interference with the replication and release of virus. Due to the greater inhibition on virus replication than 1, 2 showed better antiviral effect.
