(Dated: January 20, 2013)

A new expression for the pion form factor $F_\pi$ is proposed. It takes into account the pseudoscalar meson loops and the mixing of $\rho(770)$ with heavier $\rho(1450)$ and $\rho(1700)$ resonances. The expression has correct analytical properties and can be used in both timelike and spacelike kinematical regions. The comparison is made with the existing experimental data on $F_\pi$ collected with the detectors SND, CMD-2, KLOE, and the BaBar restricted to energies below 1 GeV. A good description of all four data sets is obtained. In the spacelike region, upon substituting the resonance parameters found in the timelike one, one obtains $F_\pi$ in agreement with the measurements of NA7 Collaboration.

I. INTRODUCTION

The pion form factor $F_\pi$ is an important characteristics of the low energy phenomena in particle physics related with the hadronic properties of the electromagnetic current in the theoretical scheme of the vector dominance model \[1,2,3\]. There are a number of expressions for this quantity used in the analysis of experimental data. The simplest approximate vector dominance model expression based on the effective $\gamma - \rho$ coupling $\propto \rho_\mu A_\mu$ \[2\],

\[ F_\pi(s) = \frac{m_\rho^2 g_{\rho\pi\pi}/g_\rho}{m_\rho^2 - s - i\sqrt{s}F_{\rho \pi \pi}(s)}, \] (1.1)

(for notations see Sec. \[III\]) does not possess the correct analytical properties upon the continuation to the unphysical region $0 \leq s < 4m_\rho^2$ and further to the spacelike region $s \leq 0$, nor does it takes into account the mixing of the isovector $\rho$-like resonances. Since, phenomenologically, \[5\] $g_{\rho\pi\pi}/g_\rho$ is not equal to unity—to be precise,

\[ g_{\rho\pi\pi}/g_\rho = \left(\frac{3m_\rho\Gamma_{\rho\pi\pi}\Gamma_{\rho\rho}}{2\alpha^2 q_\rho^2}\right)^{1/2} \approx 1.20 \] (1.2)

—the correct normalization $F_\pi(0) = 1$ is satisfied by Eq. (1.1) only approximately. Hereafter, $\alpha = 1/137$ stands for the fine structure constant. The formula of Gounaris and Sakurai \[6\] respects the above normalization condition and has the correct properties under analytical continuation. However, being based on some sort of effective radius approximation for the single $\rho(770)$ resonance, it is not suited for taking into account the mixing of $\rho(770)$ with heavier isovector mesons. The expression analogous to Eq. (1.1) based on the gauge invariant $\gamma - \rho$ coupling $\propto \rho_\mu A_\mu$ \[2\],

\[ F_\pi(s) = 1 + \frac{g_{\rho\pi\pi}/g_\rho}{m_\rho^2 - s - i\sqrt{s}F_{\rho \pi \pi}(s)}, \] (1.3)

respect the correct normalization, but does not possesses correct analytical properties and breaks unitarity. The earlier expression \[2,5\] for $F_\pi$ takes into account the strong isovector mixing, but has the shortcoming that the above normalization condition is satisfied only approximately, within the accuracy 20%.

The applications of the Lagrangian of Kroll, Lee, and Zumino \[3\] to the calculations of $F_\pi$ with the meson loop contributions in the field-theoretic context are given, in particular, in Refs. \[9–11\]. In particular, Ref. \[10\] contains the comparison of the theoretical $F_\pi$ with the experimental data in the spacelike kinematical region. However, the authors of Ref. \[10\] refrained from the application of their expression in the timelike region despite the fact that the high statistics experimental data collected with the detectors SND \[12\] and CMD-2 \[13\] were available at that time.

The purpose of the present work is to obtain the expression for the pion form factor which possesses the correct analytical properties in the entire kinematic domain and takes into account the mixing of $\rho(770)$ with the heavier resonances $\rho(1450)$ and $\rho(1700)$. By restricting the consideration to the inclusion of the pseudoscalar meson loops $\pi^+\pi^-$ and $KK$, which admits the analytical treatment and is valid at energies below 1 GeV, the new expression is found and compared with the existing data on $F_\pi$ collected with the detectors SND \[12\], CMD-2 \[13\], KLOE \[14\], and BaBar \[15\].

Below, in Sec. \[II\] the method is described by which the loop contributions to the vector–meson propagators are taken into account. The expression for the form factor $F_\pi(s)$ is given in Sec. \[III\]. Section \[IV\] is devoted to the analysis of available new experimental data on $F_\pi(s)$ \[12–15\]. Section \[V\] contains the discussion of the obtained
Let us give some details necessary for the derivation of the expression for the pion form factor. They refer to the pseudoscalar loop contributions. For the sake of brevity, the notation
\[ \rho_1 \equiv \rho(770), \rho_2 \equiv \rho(1450), \rho_3 \equiv \rho(1700) \]  
(2.1)
is used hereafter for the isovector resonances involved in the consideration.

The starting point is the effective Lagrangian describing the SU(3) invariant interaction of the vector resonances with the pair of pseudoscalar mesons \[ 16, 17 \]. Restricted to the couplings of the isovector resonances \( \rho_i \), \( i = 1, 2, 3 \), with the pair of pions and kaons \( (P = \pi, K) \), this Lagrangian looks like
\[ \mathcal{L}_{\rho_i, PP} = i g_{\rho_i, PP} \rho_{\mu} \left\{ \frac{1}{2} [K^- \partial_\mu K^+ - K^+ \partial_\mu K^- - \overline{K}^0 \partial_\mu K^0 + K^0 \partial_\mu \overline{K}^0] + \pi^0 \partial_\mu \pi^- - \pi^- \partial_\mu \pi^0 \right\}. \]  
(2.2)
The partial width of the decay \( \rho_i \to PP \) calculated from the above effective Lagrangian, is
\[ \Gamma_{\rho_i \to PP}(s) = \frac{g_{\rho_i, PP} s^{1/2} \pi^3(s)}{48\pi}, \]  
(2.3)
where \( s \) stands for the (virtual) mass squared of the decaying resonance \( \rho_i \), and
\[ \pi^3(s) = \sqrt{1 - \frac{4m_P^2}{s}} \]  
(2.4)
is the velocity of the final meson in the rest frame of the decaying resonance. Applying the Cutkosky cutting rule to the diagram in Fig. 1 one finds that the imaginary part of the diagonal polarization operator caused by the specific real intermediate state \( PP \) is related to the corresponding partial decay width according to the expression
\[ \text{Im} \Pi_{\rho_i, PP}^P(s) = \sqrt{4\Gamma_{\rho_i, PP}(s)}. \]  
(2.5)
In the present work, the real intermediate states \( \pi^+\pi^- \), \( K^+K^- \), and \( K^0K^0 \) are taken into account, hence
\[ \Pi_{\rho_i, PP}(s) = \sum_{P=\pi^+\pi^-, K^+K^-} \text{Im} \Pi_{\rho_i, PP}^P(s). \]

The diagonal and nondiagonal polarization operators for the specific loop \( PP \) are calculated from the dispersion integral. Here the version of this integral is defined which automatically provides the condition \( \Pi_{\rho_i, PP}(0) = 0 \), in agreement with the conservation of the vector current. To this end, the dispersion relation should be written for the quantity \( \Pi_{\rho_i, PP}(s)/s \). Then, one has
\[ \Pi_{\rho_i, PP}(s) = \frac{1}{\pi} \int_{4m_P^2}^{\infty} \frac{\text{Im} \Pi_{\rho_i, PP}^P(s') ds'}{s'(s' - s - i\varepsilon)} = \frac{g_{\rho_i, PP} g_{\rho_i, PP}}{48\pi^2} \int_{4m_P^2}^{\infty} \frac{v_{P}^3(s') ds'}{s' - s - i\varepsilon}. \]  
(2.6)

One can evaluate this dispersion integral in the unphysical region \( 0 \leq s < 4m_P^2 \), where \( \text{Im} \Pi_{\rho_i, PP} = 0 \), and no pole is encountered. But, the integral is still divergent at \( s' \to \infty \). The divergence can be regularized by taking the cutoff \( s'_{\text{max}} = \Lambda^2 \). The integration can be fulfilled with the change of the integration variable \( \sigma = v_P^3(s')/(1 - 4m_P^2/s') \):
\[ I(s) \equiv \int_{4m_P^2}^{\Lambda^2} \frac{ds'}{s' - s} \left( \frac{1 - 4m_P^2}{s'} \right)^{3/2} = \int_0^{1 - 2m_P^2/\Lambda^2} d\sigma \times \frac{8m_P^2 \sigma^4}{(1 - \sigma^2)(4m_P^2 - s + \sigma^2)} - \frac{8m_P^2}{s} + 2 \left( \frac{4m_P^2}{s} - 1 \right)^{3/2} \arctan \frac{1}{\sqrt{\frac{4m_P^2}{s} - 1}} + 4 \ln \frac{\Lambda}{m_P}. \]

The logarithmic divergence can be removed by fixing \( \text{Re} I(m_P^2) = 0 \). The diagonal elements \( \Pi_{\rho_i, \rho_i} \equiv \Pi_{\rho_i, \rho_i}(s) \) can be represented in the form
\[ \Pi_{\rho_i, \rho_i} = \frac{8g_{\rho_i, \pi\pi}}{48\pi^2} \left[ \Pi_{\pi}(s, m_P^2) + \frac{1}{2} \Pi_K(s, m_P^2) \right], \]  
(2.7)
where the factor 1/2 in the second term is due to the flavor SU(3) relation \( g_{\rho_i, K\overline{K}} = \frac{1}{2} g_{\rho_i, \pi\pi} \) [see Eq. (2.2)] and that two isotopic \( \overline{K}K \) modes contribute.

The expressions for \( \Pi_{\pi, \pi}(s, m_P^2) \) and \( \Pi_{\pi, K}(s, m_P^2) \) are represented in the following form. Since the pion is the lightest hadron, the function \( \Pi_{\pi}(s, m_P^2) \) looks as
The function \( \Pi_K(s, m_V^2) \) looks different depending on the mass of the vector meson \( m_V \). If \( m_V > 2m_K \), as is the case for \( V = \rho(1450) \) and \( \rho(1700) \), the expression is

\[
\Pi_K(s, m_V^2) = 8m_K^2 \left( \frac{1}{m_V^2} - \frac{1}{s} \right) + v^3_K(m_V^2) \ln \frac{1 + v_K(m_V^2)}{1 - v_K(m_V^2)} + v^3_K(s) \left[ i\pi - \ln \frac{1 + v_K(s)}{1 - v_K(s)} \right], \quad \text{if } s \geq 4m_K^2;
\]

\[
\Pi_K(s, m_V^2) = 8m_K^2 \left( \frac{1}{m_V^2} - \frac{1}{s} \right) + v^3_K(m_V^2) \ln \frac{1 + v_K(m_V^2)}{1 - v_K(m_V^2)} + 2v^3_K(s) \arctan \frac{1}{v_K(s)}, \quad \text{if } 0 \leq s < 4m_K^2;
\]

\[
\Pi_K(s, m_V^2) = 8m_K^2 \left( \frac{1}{m_V^2} - \frac{1}{s} \right) + v^3_K(m_V^2) \ln \frac{1 + v_K(m_V^2)}{1 - v_K(m_V^2)} - v^3_K(s) \ln \frac{v_K(s) + 1}{v_K(s) - 1}, \quad \text{if } s < 0.
\]  

(2.9)

If \( m_V < 2m_K \), as is the case for \( V = \rho(770) \), the expression is

\[
\Pi_K(s, m_V^2) = 8m_K^2 \left( \frac{1}{m_V^2} - \frac{1}{s} \right) - 2v^3_K(m_V^2) \arctan \frac{1}{v_K(m_V^2)} + v^3_K(s) \left[ i\pi - \ln \frac{1 + v_K(s)}{1 - v_K(s)} \right], \quad \text{if } s \geq 4m_K^2;
\]

\[
\Pi_K(s, m_V^2) = 8m_K^2 \left( \frac{1}{m_V^2} - \frac{1}{s} \right) - 2v^3_K(m_V^2) \arctan \frac{1}{v_K(m_V^2)} + 2v^3_K(s) \arctan \frac{1}{v_K(s)} \quad \text{if } 0 \leq s < 4m_K^2;
\]

\[
\Pi_K(s, m_V^2) = 8m_K^2 \left( \frac{1}{m_V^2} - \frac{1}{s} \right) - 2v^3_K(m_V^2) \arctan \frac{1}{v_K(m_V^2)} - v^3_K(s) \ln \frac{v_K(s) + 1}{v_K(s) - 1}, \quad \text{if } s < 0.
\]

(2.10)

The function \( v_P(s) \) \( (P = \pi, K) \) is given by Eq. (2.4), while

\[
v_P(s) = \sqrt{\frac{4m_P^2}{s}} - 1.
\]  

(2.11)

Note that the expressions Eqs. (2.8), (2.9), and (2.10) have the property that their real parts vanish at \( s = m_V^2 \):

\[
\text{Re} \Pi_{\pi,K}(m_V^2, m_V^2) = 0.
\]

III. THE EXPRESSION FOR THE PION FORM FACTOR

The new expression for the pion form factor which automatically respects the current conservation condition \( F_\pi(0) = 1 \) and possesses the correct analytical properties over the entire \( s \) axis, looks like

\[
F_\pi(s) = (g_{\gamma\rho_1, \gamma\rho_2, \gamma\rho_3}) G^{-1} \begin{pmatrix}
g_{\rho_1, \pi\pi} 
g_{\rho_2, \pi\pi} 
g_{\rho_3, \pi\pi}
\end{pmatrix} + \frac{g_{\gamma\omega} \Pi_{\rho\rho\omega}}{D_\omega \Delta} (g_{11} g_{\rho_1, \pi\pi} + g_{12} g_{\rho_2, \pi\pi} + g_{13} g_{\rho_3, \pi\pi}).
\]

(3.1)

The notations are as follows. The quantity

\[
g_{\gamma V} = \frac{m_V^2}{g_V},
\]

(3.2)

\( (V = \rho_{1,2,3, \omega}) \) is introduced in such a way that \( e g_{\gamma V} \), where \( e \) is the electric charge, is the \( \gamma V \) transition amplitude. As usual, the coupling constant \( g_V \) is calculated from the electronic width

\[
\Gamma_{V \to e^- e^+} = \frac{4\alpha^2 m_V}{3g_V^2}.
\]  

(3.3)
of the resonance $V$. The matrix of inverse propagators

$$G = \begin{pmatrix} D_{\rho_1} & -\Pi_{\rho_1 \rho_2} & -\Pi_{\rho_1 \rho_3} \\ -\Pi_{\rho_1 \rho_2} & D_{\rho_2} & -\Pi_{\rho_2 \rho_3} \\ -\Pi_{\rho_1 \rho_3} & -\Pi_{\rho_2 \rho_3} & D_{\rho_3} \end{pmatrix}$$

(3.4)

is responsible for the $\rho(770)$-$\rho(1450)$-$\rho(1700)$ mixing \[18\] \[20\], and $\Delta = \text{det} G$. See the Appendix for more detail. The inverse propagators of the $\rho_i$-resonance ($i = 1, 2, 3$) are

$$D_{\rho_i} = m_{\rho_i}^2 - s - i\Pi_{\rho_i},$$

(3.5)

where the diagonal polarization operator $\Pi_{\rho_i}$ can be expressed through the functions $\Pi_{\rho}(s, m_{\rho_i}^2)$ and $\Pi_{K}(s, m_{\rho_i}^2)$ described in Sec. \[\pi\]. The nondiagonal polarization operators are the following:

$$\Pi_{\rho_1 \rho_2} = \frac{g_{\rho_1 \rho_2}}{g_{\rho_1 \rho_1}} \Pi_{\rho_1 \rho_1},$$

$$\Pi_{\rho_1 \rho_3} = \frac{g_{\rho_1 \rho_3}}{g_{\rho_1 \rho_1}} \Pi_{\rho_1 \rho_1},$$

$$\Pi_{\rho_2 \rho_3} = \frac{g_{\rho_2 \rho_3}}{g_{\rho_1 \rho_1}} \Pi_{\rho_1 \rho_1} + s \sigma_{23}.$$  

(3.6)

The quantity $a_{23}$ is the dimensionless phenomenological free parameter. No such parameter is introduced in $\Pi_{\rho_1 \rho_2}$ and $\Pi_{\rho_1 \rho_3}$ because it would result in a shift of the $\rho(770)$ resonance peak position. See the Appendix and Refs. \[7\] \[8\].

The term $\propto \Pi_{\rho_1 \omega}$ in Eq. (3.11) takes into account the $\rho(770) - \omega(782)$ mixing. The basic quantities in this contribution are the following. The inverse propagator of the meson $\omega(782)$ is taken in the form

$$D_{\omega} = m_{\omega}^2 - s - i\sqrt{\omega} \Gamma_{\omega},$$

(3.7)

where the energy-dependent width

$$\Gamma_{\omega} \equiv \Gamma_{\omega}(s) = \Gamma_{\omega 3\pi}(s) + \Gamma_{\omega \pi\pi}(s) + \Gamma_{\omega \eta\gamma}(s)$$

includes the dominant decay mode $\omega(782) \rightarrow \pi^+\pi^-\pi^0$ and the radiative ones. The tree pion decay width is represented in the form

$$\Gamma_{\omega 3\pi}(s) = \frac{g_{\omega \rho_1 \pi}}{4\pi} W_{3\pi}(s),$$

where $W_{3\pi}(s)$ is the phase space volume of the final $\pi^+\pi^-\pi^0$ state:

$$W_{3\pi}(s) = \int_{2m_{\pi}}^{\sqrt{s-m_{\pi}^2}} dm \frac{1}{m_{\rho_1}(m^2)} \left[ D_{\rho_1}(m^2) + \left(1 - x^2\right)^2 \left(\frac{1}{D_{\rho_1}(m_{\rho_1}^2)} - \frac{1}{D_{\rho_1}(m_{\rho_1}^2)}\right)\right] dx \times$$

$$\left(1 - x^2\right)^2 \left(\frac{1}{D_{\rho_1}(m_{\rho_1}^2)} - \frac{1}{D_{\rho_1}(m_{\rho_1}^2)}\right)\right].$$

(3.8)

Here, $m$ is the invariant mass of the $\pi^+\pi^-$ pair while $m_\pm$ refers to the $\pi^\pm\pi^0$ one:

$$m_{\pm}^2 = \frac{1}{2}(s + 3m_{\pi}^2 - m^2) \pm \sqrt{\frac{4m_{\pi}^2}{m^2}},$$

(3.9)

and $q_{\pm} = (\sqrt{s}, m_\pm)$. Here and in what follows,

$$q(\sqrt{s}, m_a, m_b) = \frac{1}{2\sqrt{s}} \left[ (s - (m_a + m_b)^2) \times \right.$$

$$\left. (s - (m_a - m_b)^2) \right]^{1/2}$$

(3.10)

is the momentum of the particles $a$ or $b$ with the masses $m_a$ or $m_b$, respectively, in the rest reference frame of the decaying particle whose invariant mass is $\sqrt{s}$. The coupling constant $g_{\omega \rho \pi}^\rho$ is evaluated from the $\omega \rightarrow \pi^+\pi^-\pi^0$ decay width. The energy-dependent radiative width $\Gamma_{\omega \pi\gamma}(s)$, where $\omega = \rho_1, \omega, P = \pi, \eta, \gamma$, is related to the radiative width on the mass shell $\Gamma^{(0)}_{\omega \pi\gamma}(m_{\pi}^2)$ in accord with the relation

$$\Gamma_{\omega \pi\gamma}(s) = \frac{q^2}{q^2_{\pm}} \Gamma^{(0)}_{\omega \pi\gamma}(m_{\pi}^2),$$

(3.11)

and $q_{\pm}(s) = q(\sqrt{s}, m_P, 0)$ is the momentum of the pseudoscalar meson $P$ in the rest frame of the decaying vector meson $V$. The quantity

$$\Pi_{\rho_1 \omega} = \frac{s}{m_{\rho_1}^2} \Pi'_{\rho_1 \omega} + i \sqrt{s} \Gamma_{\omega \pi\gamma}(s) \Gamma_{\rho\pi\gamma}(s)$$

(3.12)

is the polarization operator of the $\rho(770) - \omega(782)$ mixing. The real part $s \Pi'_{\rho_1 \omega}/m_{\rho_1}^2$ is chosen in such a way that it vanishes at $s = 0$, and $\Pi'_{\rho_1 \omega}$ is a free parameter. The contributions to $\text{Im}\Pi_{\rho_1 \omega}$ from the $\gamma\gamma$ intermediate state can be neglected in comparison with the $\pi\gamma$ one. If not fitted, the masses and partial widths of particles and resonances involved in the treatment are taken from the Review of Particle Physics \[5\] \[12\], and the discussion around it. The quantities $g_{11}, g_{12}, g_{13}$ are, respectively,

$$g_{11} = D_{\rho_2} D_{\rho_3} - \Pi_{\rho_2 \rho_3}^2,$$

$$g_{12} = D_{\rho_2} \Pi_{\rho_1 \rho_2} + \Pi_{\rho_1 \rho_2} \Pi_{\rho_2 \rho_3},$$

$$g_{13} = D_{\rho_2} \Pi_{\rho_1 \rho_2} + \Pi_{\rho_1 \rho_2} \Pi_{\rho_2 \rho_3}.$$
enhancement of the effect due to the proximity of $m_\rho$ and $m_\rho'$. The same is true for other contributions violating G-parity conservation. Neglecting the above contributions results in the correct normalization $F_\rho(0) = 1$, if one takes
\[
\frac{g_{\rho_1 \pi \pi}}{g_{\rho_1}} + \frac{g_{\rho_2 \pi \pi}}{g_{\rho_2}} + \frac{g_{\rho_3 \pi \pi}}{g_{\rho_3}} = 1. \tag{3.13}
\]
Indeed, the mixings due to strong interactions $\Pi_{\rho_1,\rho_2}$ vanish at $s = 0$, and $F_\rho(0)$ reduces to the above sum. This is the reason for the $s$ in front of $a_{23}$ in Eq. (3.6). The comparison of the new expression Eq. (3.1) with the latest experimental data \cite{12,15} obtained in $e^+e^-$ annihilation is presented in the next section.

IV. THE DATA ANALYSIS AND RESULTS

The experimental data on the reaction $e^+e^- \rightarrow \pi^+\pi^-$ collected by the collaborations SND \cite{12}, CMD-2 \cite{13}, KLOE \cite{14}, and BaBaR \cite{15} are chosen for the analysis in the framework of the field-theory-inspired approach to the pion form factor presented in this work. As for the BaBaR data set, we restrict ourselves by the points with $\sqrt{s} \leq 1$ GeV, because, at the first stage of the study, the proposed expression for the polarization operator is restricted to include only $\pi^+\pi^-$ and $K\bar{K}$ loops.

The original $e^+e^- \rightarrow \pi^+\pi^-$ data of the SND, CMD-2, and KLOE Collaborations are presented in two distinct forms. The first one is the form factor with the vacuum polarization effect included. The BaBaR Collaboration does not present their results in this form. The second form is the so-called bare cross section. This quantity is undressed from the vacuum polarization effects, but includes the final state radiation. All four groups present their data in this form. For the purpose of uniformity of presentation, the analysis of the present work refers to the bare cross section
\[
\sigma_{\text{bare}} = \frac{8\pi\alpha^2}{3s^{5/2}} |F_\pi(s)|^2 q_\pi(s) \left[1 + \frac{\alpha}{\pi} a(s)\right], \tag{4.1}
\]
where $F_\pi(s)$ is given by Eq. (4.1),
\[
q_\pi(s) = \sqrt{s}v_\pi(s)/2
\]
is the momentum of the final pion, and the function $a(s)$ allows for the radiation of a photon by the final pions. In the case of the pointlike pions, it has the form \cite{12,22,25}
\[
\begin{align*}
a(s) &= 1 + \frac{v_\pi^2}{v_\pi^2} \left[4L_2(s) \left(1 - \frac{v_\pi}{1 + v_\pi}\right) + 2L_2(s) \left(1 - \frac{v_\pi}{1 + v_\pi}\right) - 3\ln \frac{4}{1 - v_\pi} - 4\ln v_\pi + \frac{5}{v_\pi^2} \left(\frac{1}{4}(1 + v_\pi^2)^2 - 2\right) \ln \frac{1 + v_\pi}{1 - v_\pi} + 3(1 + v_\pi^2)\right] \\
&= 1 + \frac{v_\pi^2}{v_\pi^2} \left[4L_2(s) \left(1 - \frac{v_\pi}{1 + v_\pi}\right) + 2L_2(s) \left(1 - \frac{v_\pi}{1 + v_\pi}\right) - 3\ln \frac{4}{1 - v_\pi} - 4\ln v_\pi + \frac{5}{v_\pi^2} \left(\frac{1}{4}(1 + v_\pi^2)^2 - 2\right) \ln \frac{1 + v_\pi}{1 - v_\pi} + 3(1 + v_\pi^2)\right]. \tag{4.2}
\end{align*}
\]
Here, $v_\pi \equiv v_\pi(s)$ is given by Eq. (2.4), and
\[
L_2(x) = -\int_0^x dt \ln(1 - t)/t.
\]

First of all, no fit with the single $\rho(770)$ resonance contribution, based on Eq. (3.1) in which both $g_{\rho_2 \pi \pi}$ and $g_{\rho_3 \pi \pi}$ are set to zero, is capable of satisfactory description of all four data sets, even with the $\rho\omega$ mixing effect being taken into account. Although the formula with the single resonance works well in the $\rho\omega$ resonance region, the curve at the far-right shoulder of the $\rho(770)$ resonance peak does not follow the data points.

Taking into account the resonance $\rho_2$, but with the neglect of the $\rho_3$ one, results in a rather poor fit, too. This is because the normalization condition $F_\rho(0) = 1$ reduces, in this case, to the rather restrictive sum rule
\[
\frac{g_{\rho_1 \pi \pi}}{g_{\rho_1}} + \frac{g_{\rho_2 \pi \pi}}{g_{\rho_2}} = 1,
\]
which fixes completely the $\rho_2$ contribution to the $e^+e^- \rightarrow \pi^+\pi^-$ reaction amplitude in a way that forbids the successful fit. Specifically, the ratio $g_{\rho_2 \pi \pi}/g_{\rho_2}$ turns out to be too small due to the fact that the universality condition $g_{\rho_1 \pi \pi}/g_{\rho_1} \approx 1$ is satisfied for the couplings of $\rho(770)$. See Eq. (1.2). Hence, the $\rho_2$ resonance contribution turns out to be smaller than necessary for reconciling the calculations with the data. The third resonance $\rho_3 \equiv \rho(1700)$ is required in order both to preserve the approximate universality condition and to allow a freedom in the variation of the $\rho_2 \equiv \rho(1450)$ couplings.

Free parameters, which should be determined from comparison with the existing data \cite{12,15}, are the masses of the resonances $\rho(770)$ and $\omega(782)$, the coupling constants $g_{\rho_1,2,3 \pi \pi}$ of the resonances $\rho_{1,2,3}$ with the $\pi^+\pi^-$ state, the coupling constants $g_{\rho_1,2}$ and $g_{\omega}$ parametrizing the $\rho_{1,2}$ and $\omega(782)$ leptonic decay widths [see Eq. (3.3)], and the real part of the polarization operator of the $\rho(770) - \omega(782)$ mixing $\Pi_{\rho_2\rho_3}$. Note that $g_{\rho_3}$ is not free but should be determined from the sum rule Eq. (3.13). At last, there is the parameter $a_{23}$ [see Eq. (3.3)] that defines Re$\Pi_{\rho_2\rho_3}$. Since we restrict our analysis to the energy range below 1 GeV, the masses of the resonances $\rho(1450)$ and $\rho(1700)$ are fixed to, respectively, $m_{\rho_2} = 1.45$ GeV and $m_{\rho_3} = 1.7$ GeV.
So, the total set of free parameters is

\[
m_{\rho_1}, g_{\rho_1 \pi \pi}, g_{\rho_1}, m_\omega, g_\omega, \Pi_{\rho_1 \omega}, g_{\rho_2 \pi \pi}, g_{\rho_2},
\]

\[
g_{\rho_3 \pi \pi}, a_{23}.
\]

Their obtained values, found from fitting the bare cross section Eq. (4.1), side-by-side with the corresponding \(\chi^2\) per number of degrees of freedom, are listed in Table I separately for the four independent measurements of SND [12], CMD-2 [13], KLOE [14], and the BaBaR data [15] restricted to the low-energy range \(\sqrt{s} \leq 1\) GeV by the reason explained earlier. The bare cross section evaluated with the parameters of Table I is compared with the SND [12], CMD-2 [13], KLOE [14], and BaBaR [15] data shown in Figs. 2, 3, 4, and 5, respectively.

As far as the specific values of the obtained parameters in the Table I are concerned, those corresponding to the \(\rho(770) - \omega(782)\) resonance system agree satisfactorily for all four experiments [12–15]. The agreement of the coupling constants of the resonances \(\rho(1450)\) and \(\rho(1700)\) is poor but, taking into account the large uncertainties in their determination, is not crucial. This is justifiable, because the energy range \(\sqrt{s} \leq 1\) GeV is not a proper place for extraction of the coupling constants of the above resonances. The widths of \(\rho(1450)\) and \(\rho(1700)\), in their respective energy ranges, are known to be saturated by the complicated final states \(\rho \pi \pi, \omega \pi, \text{etc., not the } \pi^+ \pi^-\) one [5]. Taking into account these decay modes is necessary at energies \(\sqrt{s} > 1\) GeV. Unfortunately, taking into account the real parts of the polarization operators arising due to the mentioned complicated states is hardly
TABLE I. The resonance parameters found from fitting the data from SND [12], CMD-2 [13], KLOE10 [14], and the BaBar data [15] restricted to the energies $\sqrt{s} \leq 1$ GeV.

V. DISCUSSION.

An important check of the expression for the pion form factor Eq. (5.1) and the consistency of the fits is the continuation to the spacelike region $t < 0$ accessible in the scattering processes. To this end, one should take the branch with $s < 0$ in $\Pi_{\pi \pi}$ \( s, m_{\rho_1}^2 \) [see Eqs. (2.8), (2.9), and (2.10)] and replace $s \rightarrow t$. Having in mind that the $\rho(770) - \omega(782)$ mixing in the region $t < 0$ is negligibly small one can calculate $F_\pi(t)$ in this region. The results are shown in Fig. 6 where the comparison with the NA7 data [21] is presented for all four fits considered in the present work. We emphasize that the data [21] are not included to the fits. Hence, a good agreement, demonstrated in Fig. 6, makes the evidence in favor of the validity of Eq. (5.1) for the pion form factor.

Using the resonance parameters of Table I one can calculate, in particular, such important characteristics as the charged pion radius $r_\pi$, defined as the square root of the root-mean squared radius,

$$r_\pi = \sqrt{\langle r^2 \rangle},$$

of the spherical symmetric electric charge distribution

$$F_\pi(q) = \int d^3 r \rho(r)e^{iqr} \approx F_\pi(0) - \frac{q^2}{6} \int \rho(r) r^2 d^3 r = F_\pi(0) + \frac{t}{6}\langle r^2 \rangle,$$

where $t = -q^2$. One gets

$$r_\pi = \sqrt{\frac{6}{\lambda} \frac{dF_\pi(t)}{dt}} \bigg|_{t \rightarrow 0}. \quad (5.2)$$

Evaluating $r_\pi$ with the parameters of Table I one obtains the results presented in the first row of Table I. For comparison, the averaged value of the pion charge radius cited by the PDG [5] is $r_\pi = 0.672 \pm 0.008$ fm.

If one considers the single $\rho(770)$ resonance, then its inverse propagator near $s = m_{\rho_1}^2$ can be represented as

$$D_{\rho_1} = m_{\rho_1}^2 - s + (m_{\rho_1}^2 - s) \frac{d\Pi_{\rho_1 \rho_1}(s)}{ds} \bigg|_{s=m_{\rho_1}^2}.$$
Comparing Eq. (5.3) with Eq. (1.1) one can see that one should make the renormalization

$$i\sqrt{s}\Gamma_{\rho_1 \pi\pi}(s),$$

The behavior of $Re\Pi_{\rho_1 \rho_1}(s)$ is shown in Fig. 6. Comparing Eq. (5.3) with Eq. (1.1) one can see that one should make the renormalization

$$g_{\rho_1 \pi\pi} \rightarrow Z_{\rho}^{-1/2} g_{\rho_1 \pi\pi},$$

$$g_{\rho_1} \rightarrow Z_{\rho}^{1/2} g_{\rho_1},$$

where

$$Z_{\rho} = 1 + \frac{d Re\Pi_{\rho_1 \rho_1}(s)}{ds} \bigg|_{s=m_{\rho_1}^2},$$

in order to reduce Eq. (5.3) to the conveniently used form with $m_{\rho_1}$ being the physical mass of the resonance. This results in the renormalization of the $\pi^+\pi^-$ and $e^+e^-$ partial widths of the $\rho(770)$:

$$\Gamma_{\rho_1 \pi\pi} \rightarrow \Gamma_{\rho_1 \pi\pi}^{(phys)} = \frac{\Gamma_{\rho_1 \pi\pi}}{Z_{\rho}},$$

$$\Gamma_{\rho_1 ee} \rightarrow \Gamma_{\rho_1 ee}^{(phys)} = \frac{\Gamma_{\rho_1 ee}}{Z_{\rho}}.$$  

The numerical values of the renormalization constant $Z_{\rho}$ are given in Table II side-by-side with the $\pi^+\pi^-$ and $e^+e^-$ partial widths of the $\rho(770)$. One can see that $Z_{\rho}$ brings the "bare" widths (without the superscript "phys") closer to the values $\Gamma_{\rho\pi\pi} = 149.1 \pm 0.8$ MeV and $\Gamma_{\rho ee} = 7.04 \pm 0.06$ keV cited in the Review of Particle Physics [4].

Another important characteristic of the low-energy hadronic physics is the phase shift $\delta_{\pi\pi}^1$ of $\pi\pi$ scattering in
of the vector-isovector channel with the quantum numbers parameters from the fit of the BaBaR data, shown here.

One can restrict oneself by the contribution of the $\pi\pi$ scattering factor $\delta^1$ of $\pi\pi$ scattering. The data are, respectively, Protopopescu et al. [26] and Estabrooks et al. [27]. The curves corresponding to the parameters obtained from fitting the SND, CMD-2, and KLOE data are not shown because they coincide with the curve evaluated using the parameters from the fit of the BaBaR data, shown here.

The vector-isovector channel with the quantum numbers of $\rho(770)$. At energies below the $\omega\pi$ and $K\bar{K}$ production thresholds, $\delta^1_1$ is given by the phase of the pion form factor

$$\delta^1_1 = \arctan \frac{\text{Im} F_\pi}{\text{Re} F_\pi}$$

(5.6)

where $F_\pi$ is given by Eq. (3.1) upon neglecting the contribution of $\omega\pi$ mixing $\propto \Pi_{\rho\omega}$. The plot of $\delta^1_1$, obtained using parameters extracted from fitting the low-energy portion of the BaBaR data [12, 13], is shown in Fig. 8 where the comparison with the data [20, 26] is presented. Note that the resonance parameters, extracted from three other sets of data [12, 14], result in the curves for $\delta^1_1$ coincident with that shown in Fig. 8. Having in mind that the data on the phase shift were not included in the fits, the agreement of the calculated $\delta^1_1$ with the measured one is satisfactory.

VI. CONCLUSION

It is shown that the new formula for $F_\pi(s)$, Eq. (3.1), gives a good description of the latest experimental data [12, 15] on the production of the $\pi^+\pi^-$ pair in $e^+e^-$ annihilation at $\sqrt{s} < 1$ GeV. In this low-energy domain, one can restrict oneself by the contribution of the $\pi^+\pi^-$ and $K\bar{K}$ loops to both diagonal and nondiagonal polarization operators. In principle, other intermediate states could be taken into account, at least numerically. However, heavier isovector resonances $\rho(1450)$ and $\rho(1700)$ are known to have other decay modes besides $\pi^+\pi^-$ and $K\bar{K}$, such as $\omega\pi$, $a_1\pi$ etc. The treatment should include the energies $\sqrt{s} \leq 2$ GeV where the coupling constants with the above states could be determined. No data exist on these decay modes of the quality comparable with the $\pi^+\pi^-$ data [12, 15]. Hence, at present, the restriction to the domain $\sqrt{s} < 1$ GeV and to the pseudoscalar loops seems justifiable.

ACKNOWLEDGMENTS

We are grateful to M. N. Achasov for numerous discussions which stimulated the present work.

Appendix A: The finite width and the resonance mixing

Some details necessary for taking into account the finite width effects and the resonance mixing are given in this Appendix. The meaning of the diagonal polarization operator $\Pi_{RR}(s)$ is that it modifies the inverse bare propagator of the resonance $R$ with the mass $m_R$,

$$D_R^{(0)}(s) \equiv D_R^{(0)}(m^2_R - s),$$

in the following way:

$$\frac{1}{D_R(s)} = \frac{1}{D_R^{(0)}} + \frac{1}{D_R^{(0)}} \Pi_{RR}(s) \frac{1}{D_R^{(0)}} + \frac{1}{D_R^{(0)}} \Pi_{RR}(s) \frac{1}{D_R^{(0)}} \Pi_{RR}(s) \frac{1}{D_R^{(0)}} + \cdots =$$

$$\frac{1}{D_R^{(0)} - \Pi_{RR}(s)}.$$

In particular, this formula takes into account the finite width effects

$$D_R(s) = m^2_R - s - \text{Re} \Pi_{RR}(s) - i\sqrt{s} \Gamma_{R\pi\pi}(s).$$

(A1)

In principle, the mixing of the isovector resonances $\rho(770)$, $\rho(1450)$, and $\rho(1700)$ can be strong, especially because of the common decay modes, for example, the $\pi^+\pi^-$ one. It can be taken into account in the field-theory-inspired approach based on summing to all orders of the loop corrections to the bare propagators of vector mesons [7, 8, 12, 20]. The term "bare" means that the propagators are not distorted by the mixing. The scheme can be demonstrated by taking the two-resonance mixing as an example [20]. It reduces in this case to the following replacements:

$$\frac{1}{D_R} \rightarrow \frac{1}{D_R} + \frac{1}{D_R} \Pi_{RR'} \frac{1}{D_R} \Pi_{RR'} \frac{1}{D_R} + \cdots =$$

$$\frac{D_{RR'}(s)}{D_{RR'}(s) - \Pi_{RR'}} \equiv (G^{-1})_{RR'}.$$
where, in accord with the adopted definition, Re Πρ1ρ1(m2ρ1) = 0. One can see from Eq. (A3) that there is a shift in the ρ1 resonance peak position due to the mixing of ρ1 with the resonance ρ2:

$$\Delta m^2_{\rho_1} = -\text{Re} \frac{\Pi_{\rho_2\rho_2}(m^2_{\rho_1})}{m^2_{\rho_2} - m^2_{\rho_1} - \Pi_{\rho_2\rho_2}(m^2_{\rho_1})} \approx \frac{-\text{Re} \left[ \Pi_{\rho_2\rho_2}(m^2_{\rho_1}) \right]}{m^2_{\rho_2} - m^2_{\rho_1}}, \quad (A4)$$

where we neglect Πρ2ρ2(m2ρ1) in comparison with the mass difference squared m2ρ2 − m2ρ1. Indeed, using the plots in Fig. 7 the relation

$$\Pi_{\rho_2\rho_2} = \left( \frac{g_{\rho_2\pi\pi}}{g_{\rho_1\pi\pi}} \right)^2 \Pi_{\rho_1\rho_1},$$

Eq. (2.3), Eq. (2.7), and gρ2ππ ≈ 0.8 (see Table I), one obtains the estimate

$$\frac{\Pi_{\rho_2\rho_2}(m^2_{\rho_1})}{m^2_{\rho_2} - m^2_{\rho_1}} \lesssim (0.2 + 1.5i) \times 10^{-3}.$$  

In the case of the well-studied resonance ρ1 = ρ(770), it is natural to expect that the visible peak position with a good accuracy coincides with the bare mass mρ1. This follows from the definition Re Πρ1ρ1(m2ρ1) = 0 adopted in the present work. In order to preserve the above coincidence, the natural demand is to set Re Πρ1ρρ2 = 0. Since, in Eq. (A3), Re Π2ρ2ρ2 = (Re Πρ2ρ2)2 − (Im Πρ2ρ2)2, then, to be precise, some mass shift survives which is equal to

$$\Delta m_{\rho_1} \approx \frac{m_{\rho_1}^2 \Pi_{\rho_1\rho_1}^2}{2(m^2_{\rho_2} - m^2_{\rho_1})} \left( \frac{g_{\rho_2\pi\pi}}{g_{\rho_1\pi\pi}} \right)^2.$$  

However, even in the worse case gρ2ππ = 0.8 (see Table I) where the magnitudes of the coupling constants extracted from the specific fits are given), this shift is estimated at the level of 0.1 MeV. This estimate falls within the errors of mρ1, quoted in Table I. Having in mind the three-resonance case, we set Re Πρ1ρρ3 = 0. Such a type of justification is not applicable for the poorly studied resonances ρ2 = ρ(1450) and ρ3 = ρ(1700); hence, the parameter α23 fixing Re Πρ2ρ3 remains free.

The generalization to the case of three (and any number of) resonances ρ1, ρ2, and ρ3 is straightforward. The matrix of inverse propagators is given by Eq. (3.4). The matrix of propagators is

$$G^{-1} = \frac{1}{\Delta} \begin{pmatrix} g_{11} & g_{12} & g_{13} \\ g_{12} & g_{22} & g_{23} \\ g_{13} & g_{23} & g_{33} \end{pmatrix},$$

where

$$g_{11} = D_{\rho_1} D_{\rho_3} - \Pi_{\rho_1\rho_3},$$

$$g_{22} = D_{\rho_2} D_{\rho_3} - \Pi_{\rho_2\rho_3},$$

$$g_{33} = D_{\rho_3} D_{\rho_3} - \Pi_{\rho_3\rho_3},$$

$$g_{12} = D_{\rho_1} D_{\rho_2} - \Pi_{\rho_1\rho_2},$$

$$g_{13} = D_{\rho_1} \Pi_{\rho_1\rho_3} + \Pi_{\rho_1\rho_3} \Pi_{\rho_3\rho_3},$$

$$g_{23} = D_{\rho_2} \Pi_{\rho_2\rho_3} + \Pi_{\rho_2\rho_3} \Pi_{\rho_3\rho_3} - D_{\rho_3} \Pi_{\rho_2\rho_3} - D_{\rho_2} \Pi_{\rho_2\rho_3} - D_{\rho_3} \Pi_{\rho_1\rho_3} \Pi_{\rho_1\rho_3}. \quad (A5)$$

Note that, deep in the spacelike domain, the quantity 1/Δ and, as a consequence, the pion form factor have a pole at $-q^2 = 87$, 82, 97, and 95 GeV, when evaluated with the resonance parameters obtained from the fit of, respectively, SND [12], CMD-2 [13], KLOE [14], and BaBar [15] data. This pole is the analog of the famous Landau pole.

In addition to the strong mixing between the isovector resonances, one should include also the isovector-isoscalar

\[ \frac{1}{D_{R'}} = \frac{1}{D_{R'}} + \frac{1}{D_{R'}} \Pi_{RR'} \frac{1}{D_{R'}} \frac{1}{D_{R'}} + \cdots = \frac{1}{D_{R}D_{R'} - \Pi_{RR'}^2} = (G^{-1})_{R'R'}, \]

\[ \frac{\Pi_{RR'}}{D_{R}D_{R'}} \rightarrow \frac{\Pi_{RR'}}{D_{R}D_{R'}} + \frac{(\Pi_{RR'})^3}{(D_{R}D_{R'})^2} + \cdots = \frac{\Pi_{RR'}}{D_{R}D_{R'} - \Pi_{RR'}^2} = (G^{-1})_{RR'}. \]
\( \rho_1 - \omega(782) \) mixing arising due to small G-parity breaking. Then, the matrix of inverse propagators can be written in the form

\[
G_{\text{tot}} = \begin{pmatrix}
D_{\rho_1} & -\Pi_{\rho_1 \rho_2} & -\Pi_{\rho_1 \rho_3} & -\Pi_{\rho_1 \omega} \\
-\Pi_{\rho_1 \rho_2} & D_{\rho_2} & -\Pi_{\rho_2 \rho_3} & -\Pi_{\rho_2 \omega} \\
-\Pi_{\rho_1 \rho_3} & -\Pi_{\rho_2 \rho_3} & D_{\rho_3} & -\Pi_{\rho_3 \omega} \\
-\Pi_{\omega \rho_1} & -\Pi_{\omega \rho_2} & -\Pi_{\omega \rho_3} & D_{\omega}
\end{pmatrix} \quad \text{(A6)}
\]

In this case, the pion form factor is written as follows:

\[
F_\pi(s) = (g_{\gamma \rho_1}, g_{\gamma \rho_2}, g_{\gamma \rho_3}, g_{\gamma \omega}) G^{-1}\begin{pmatrix}
g_{\rho_1 \pi \pi} \\
g_{\rho_2 \pi \pi} \\
g_{\rho_3 \pi \pi} \\
g_{\omega \pi \pi}
\end{pmatrix}, \quad \text{(A7)}
\]

The coupling constant \( g_{\omega \pi \pi} \) describes the direct \( \omega \to \pi^+ \pi^- \) transition arising due to the violation of G-parity conservation side-by-side with the mixing mechanism. However, it is known \([7]\) that, since the \( \pi^+ \pi^- \) channel dominates the \( \rho_1 \) decay width, \( g_{\omega \pi \pi} \) is almost canceled in the effective \( \omega \to \pi^+ \pi^- \) transition amplitude due to the compensation among imaginary parts of \( \Pi_{\rho_1 \omega} \) and the inverse \( \rho_1 \) propagator. Indeed, allowing for both the mixing and direct transition, one can write the effective \( \omega \pi \pi \) coupling constant in the form

\[
g_{\omega \pi \pi}^{(\text{eff})} \approx g_{\omega \pi \pi} - \frac{(\text{Re}\Pi_{\rho_1 \omega} + i\text{Im}\Pi_{\rho_1 \omega}) g_{\rho_1 \pi \pi}}{m_{\pi}^2 - m_{\rho_1}^2 - i\sqrt{s}(\Gamma_{\omega} - \Gamma_{\rho_1 \pi \pi})} \approx \frac{1}{m_{\pi}^2 - m_{\rho_1}^2 - i\sqrt{s}(\Gamma_{\omega} - \Gamma_{\rho_1 \pi \pi})} \left( g_{\omega \pi \pi} \sqrt{s}(\Gamma_{\omega} - \Gamma_{\rho_1 \pi \pi}) \right)
\]

where \( \text{Im}\Pi_{\rho_1 \omega} \) differs from \( \text{Im}\Pi_{\rho_2 \omega} \) by the absence of the term \( \propto g_{\omega \pi \pi} \). Hence, one can safely neglect the coupling constant \( g_{\omega \pi \pi} \). This circumstance was not properly accounted for in our earlier work, Ref. \([7]\). The isovector-isoscalar type of weak mixing is essential only for the \( \rho(770) - \omega(782) \) system because it is enhanced due to the small mass difference of these resonances. See Eq. \((A8)\). As for other isovector-isoscalar mixings \( \rho(1450) - \omega(782) \) and \( \rho(1700) - \omega(782) \), there is no enhancement, due to the mass proximity, and one can neglect \( \Pi_{\rho_2 \omega} \). Taking the latter assumption into account and allowing for the \( \rho_1 \omega \) mixing to first order, one can approximate the propagator matrix \( G^{-1} \) in Eq. \((A7)\) by the expression

\[
G_{\text{tot}}^{-1} \approx \frac{1}{\Delta} \begin{pmatrix}
g_{11} & g_{12} & g_{13} & \frac{g_{11}\Pi_{\rho_1 \omega}}{D_{\rho_1}} \\
g_{12} & g_{22} & g_{23} & \frac{g_{12}\Pi_{\rho_1 \omega}}{D_{\rho_2}} \\
g_{13} & g_{23} & g_{33} & \frac{g_{13}\Pi_{\rho_1 \omega}}{D_{\rho_3}} \\
g_{11}\Pi_{\omega \rho_1} & g_{12}\Pi_{\omega \rho_2} & g_{13}\Pi_{\omega \rho_3} & \frac{g_{13}\Pi_{\omega \rho_1} D_{\omega}}{\Delta}
\end{pmatrix},
\]

where \( g_{ij} \) and \( \Delta \) are given by Eq. \((A5)\). The final approximate expression for the pion form factor \( F_\pi \equiv F_\pi(s) \) given by Eq. \((A1)\) is obtained by inserting this approximate expression to Eq. \((A7)\) and by neglecting the coupling constant of the direct decay \( g_{\omega \pi \pi} \).
