INTRODUCTION

Laparoscopic appendectomy has been used progressively as an emergency procedure. Since laparoscopic appendectomy described by Semm1 in 1983, it has improved technically as a three port technique for appendectomy. In children, single port laparoscopic appendectomy is difficult because they have a small peritoneal cavity for manipulation of laparoscopic instruments. Therefore, we performed transumbilical laparoscopic assisted single port appendectomy (hybrid appendectomy) in children.

Methods: From March 2010 to July 2012, we performed transumbilical laparoscopic assisted single port appendectomy in 53 children. We made a vertical incision to the umbilicus approximately 1.5 cm, and a wound retractor (Applied Medical Resources Co., Ltd., Rancho Santa Margarita) was placed in the umbilical incision, and appendix exteriorized the extraperitoneum through the wound retractor. Appendectomy was performed conventionally. We had no conversion cases for laparotomy.

Results: A total of 53 patients, 29 females and 24 males, with a mean age of 8.5±2.0 years were enrolled in this retrospective study. The mean operative time was 29.4±9.4 minutes. There was no occurrence of complication or mortality. BMI was 17.8±4.9 kg/m². And mean hospital stay was 3.2±1.0 days.

Conclusion: In children, transumbilical single port laparoscopic appendectomy is technically difficult because they have a small peritoneal cavity. However, transumbilical laparoscopic assisted single port appendectomy (hybrid appendectomy) appears to be a safe and effective technique for use in children, which allows for achievement of nearly scarless surgery.

Key words: Appendectomy, Laparoscopy, Children

MATERIALS AND METHODS

From December 2008, we performed 53 cases transumbilical laparoscopic assisted single port appendectomy in children. The appendicitis was diagnosed with physical examination, abdominal sonography, and abdominal CT and periappendiceal abscess was excluded for laparoscopic surgery. They received therapeutic antibiotics intravenously at the induction of anesthesia, and after surgery. All these procedures were performed by an experienced single surgeon in single site appendectomy.

1) Operative technique

The surgeon stood on the left side and the assistant on the right side of the patient while the monitor was placed on the right side. Under the general anesthesia, a 1.5 cm vertical incision to the umbilicus was made. After a window was made, a small sized wound retractor (Alexis, Applied Medical resources Co., Ltd., rancho Santa Margarita) was inserted...
Fig. 1. The appendix was exteriorized through the wound retractor.

through the incision and rolled over to cover and stretch it. The glove was then attached on the wound retractor ring, which was rolled over it to provide a seal. After pneumoperitoneum was established, a 5 mm 30 degree videoscope was inserted into the third finger of the glove and the other trocar inserted to other finger of the glove. On videoscope, appendix was identified and exteriorized through the wound retractor (Fig. 1). Attached glove was removed from the wound retractor and then appendectomy was performed conventionally. Umbilical skin incision was approximated by subcutaneous sutures and compressive dressing was done with peanut ball sponge (Fig. 2).

RESULTS

This study included 29 females and 24 males with a mean age of 8.5±2.0 years. The mean BMI was 17.9±4.9 kg/m² (Height; 1.26~1.49 m, Weight; 16~59 kg). The procedure was performed on 53 patients, without alteration of conventional appendectomy, appendectomy with drainage was 5 cases. The mean operative time was 29.4±9.4 minutes. Postoperatively oral liquids were started within 10 hours and a soft diet within 24 hours. Pathologic findings were commonly acute catarrhal appendicitis and acute supplicative appendicitis. All patients was not developed postoperative complication. The median hospital stay was 3.2±1.0 days. The postoperative scar was hidden in the wrinkle of the umbilicus.

DISCUSSION

The laparoscopic appendectomy started by Semm in 1983, offering a promising alternative. In 1992, Gilchrist et al. described first series of laparoscopic appendectomy in pediatric patients. Metaanalysis of 23 studies that included 6,477 pediatric patients and compared operative data and outcomes of open and laparoscopic methods, gave same evidence about validity of procedures. A reduced incidence of wound infection and ileus rate are major advantages of laparoscopy. Shorter postoperative hospital stay after laparoscopy was also reported.

The single port transumbilical laparoscopic assisted appendectomy (TULAA) technique, as described by Esposito, provided the additional advantages of the combined approach. An idea to apply principles and strategies of laparoscopy and compile advantage resulted in development laparoscopic assisted techniques. These techniques consisted of two parts; intra-abdominal mobilization and extracorporeal removal of the appendix. The procedure is rarely used because all intra-abdominal dissection must be done with an instrument that passes through the working channel of the telescope. For this reason, special equipment is necessary, including a telescope with working channel and long shift instruments.

The hybrid technique, which combines laparoscopy with standard open techniques, the appendix is pulled through the umbilicus in children or a right lower quadrant incision in adults for performance of a traditional open appendectomy extracorporeally. The hybrid technique in which the appendix is pulled through the single incision in the umbilicus is possible only in the pediatric population due to the close proximity of the appendix and the umbilicus. The umbilicus is located in the thinner area of the abdominal wall, and this condition makes the port introduction easier as well as motion of the instrument in all directions.

In pediatric surgery, hybrid and single-port assisted laparoscopic appendectomies have been popularized because of
the surgeon’s ability to grasp the appendix and exteriorize it through the umbilical port to perform an appendectomy extracorporeally.11,15

Extracorporeal ligation of the mesoappendix and reduced time needs for port access and closure seems to be responsible for difference between TULAA and laparoscopic appendectomy.16

We can easily perform appendectomy in children.

Exteriorization of an intraabdominal drain through the umbilical wound was not considered due to an increased risk of cutaneous infection at this level and the possibility of incisional hernia. Moreover, insertion of a 5-mm trocar at the hypogastric level may help in safe handling of intestinal loops and would facilitate placement of a drain through the cutaneous orifice.14 We placed J-P drain in 5 cases to the right lower abdominal area through the umbilical incision.

Different studies describing transumbilical appendectomy have been published in the literature. In 1996, Kala et al.17 performed the procedure through one umbilical port with extracorporeal section of the appendicular structures. A large variety of umbilical procedures with or without exteriorization of the appendix have been reported in clinical series of pediatric patients.10,18,19 A group at the University of Naples18 described transumbilical appendectomy using a single trocar and a flexible laparoscope with extracorporeal section of appendicular structures. However, the authors indicate the need to use supplemental trocars or to perform a small laparotomy in McBurney’s point when appendicular inflammations or intraperitoneal adherences in the right iliac fossa are found.14

We used a transumbilical single port that consisted of a wound retractor and a surgical glove. This device has several merits, it can prevent subcutaneous emphysema, as well as port-site infection and bleeding, due to the tamponade effect of the wound retractor. During surgery, rolling up the ring of the wound retractor with surgical glove is important to prevent the leakage of insufflated gas, and to prevent contamination of the wound.

All our patients could be operated by transumbilical laparoscopic assisted appendectomy technique without conversions or additional ports and they had an uneventful recovery. If necessary, the surgeon can convert laparoendoscopic single-site surgery (LESS) into a conventional laparoscopic procedure by adding another trocar while preserving safety for the patient.14

CONCLUSION

In conclusion, we report our experiences of transumbilical laparoscopic assisted appendectomy (hybrid appendectomy) in 53 patients. All patients were operated successfully without any complications. It could be an appropriate minimally invasive technique for appendectomy in children.
