Abstract

We analyse the CP asymmetry for $B_s \to \gamma\gamma$ in the two Higgs doublet model with tree level flavor changing currents (model III) and three Higgs doublet model with $O_2$ symmetry in the Higgs sector, including $O_7$ type long distance effects. Further, we study the dependencies of the branching ratio $Br(B_s \to \gamma\gamma)$ and the ratio of $CP$-even and $CP$-odd amplitude squares, $R = |A^+|^2/|A^-|^2$, on the $CP$ parameter $\sin\theta$. We found that, there is a weak $CP$ asymmetry, at the order of $10^{-4}$. Besides, the branching ratio $Br(B_s \to \gamma\gamma)$, and also $R$ ratio, is not sensitive to the $CP$ parameter for $|\xi_N^{\mu,tt}/\xi_N^{\mu,bb}| < 1$.

1 Introduction

One of the most important classes of decays are rare B-meson decays which are induced by flavor changing neutral currents (FCNC) at loop level in the Standard Model (SM). Therefore, one can obtain quantitative information for the SM parameters, such as Cabibbo-Kobayashi-Maskawa (CKM) matrix elements, leptonic decay constants, \( CP \) ratio, etc. and the measurement of physical quantities like branching ratio \( (Br) \), \( CP \) asymmetry \( (A_{CP}) \), etc, gives important clues about the model under consideration. These decays are also sensitive to the physics beyond the SM, such as two Higgs Doublet model (2HDM), Minimal Supersymmetric extension of the SM (MSSM) [1].

\( B_s \to \gamma \gamma \) decay, which is an example of the rare B meson decays, is an important candidate to test the theoretical models and to construct new models in the framework of the planned experiments at the upcoming KEK and SLAC-B factories and existing hadronic accelerators. \( B_s \to \gamma \gamma \) decay, induced by the process \( b \to s \gamma \gamma \) in the quark level, has been studied in the SM [2]-[5] and 2HDM [6] without QCD corrections. Since the QCD corrections to the inclusive decay \( b \to s \gamma \) are large (see [7] - [10] and references therein), it is expected that they are also large in the inclusive \( b \to s \gamma \gamma \) decay and, therefore, in the exclusive \( B_s \to \gamma \gamma \) decay. With the addition of the leading logarithmic (LLog) QCD corrections, the analysis has been repeated in the SM [11]-[13], 2HDM [14], MSSM [15], and the strong sensitivity to these corrections was obtained. Recently, \( B_s \to \gamma \gamma \) decay has been calculated in the framework of model III [16] with the addition of the LLog QCD corrections and the current upper limit of the \( Br \) ratio \( Br(B_s \to \gamma \gamma) \leq 1.48 .10^{-4} \) [17] was theoretically obtained for larger values of the Yukawa coupling \( \xi_{N,bb} \) and the ratio \( |r_{tb}| = \frac{\xi_{N,tt}}{\xi_{N,bb}} > 1 \) (see Appendix C for definitions).

In the present work, we study \( B_s \to \gamma \gamma \) decay in 2HDM (model III) and three Higgs doublet model with \( O_2 \) symmetry in the Higgs sector \( (3HDM(O_2)) \) [18], with complex Yukawa couplings. In our calculations, we take into account the perturbative QCD corrections in the LLog approximation by following a method based on heavy quark effective theory (HQET) for the bound state of the \( B_s \) meson [11] and we also consider the long-distance effects due to the process \( B_s \to \phi \gamma \to \gamma \gamma \), [11]. Since the complex Yukawa couplings are chosen in the calculations, in addition to the CKM matrix elements, there is a new source for \( CP \) violation. Using this new source, we obtain \( A_{CP} \) in model III at the order of \( 10^{-4} \), which is a small effect. Furthermore, we calculate this quantity in the \( 3HDM(O_2) \) and find that there is a small decrease as compared to the former one for \( \sin \theta \leq 0.5 \). Finally, the calculations of \( Br \) and the \( CP \) ratio \( R = |A_{CP}| \) show that these physical quantities are not sensitive to the models.
under consideration for $|r_{tb}| = |\frac{\xi_{tb}}{\xi_{tt}}| < 1$ (see Section 3).

The paper is organized as follows: In section 2, we present the LLog QCD corrected amplitude for the exclusive decay $B_s \rightarrow \gamma\gamma$ and the $CP$-even $A^+$ and $CP$-odd $A^-$ amplitudes in a HQET inspired approach. Then, we calculate $A_{CP}$, assuming that the Yukawa couplings are complex in general and also derive $Br$. Finally, these calculations are repeated in the $3HDM(O_2)$ model with the redefinition of the Yukawa combination $\lambda_\theta$ (see eq. (20)). Section 3 is devoted to our analysis of the physical quantities under consideration and our conclusions. In the Appendix, we give a brief explanation about the model III and $3HDM(O_2)$ which we study. Further, we present the operator basis and the Wilson coefficients responsible for the inclusive $b \rightarrow s\gamma\gamma$ decay in the model III. Finally, we give the explicit forms of some functions appearing in the Wilson coefficients.

2 Leading logarithmic improved short-distance contributions in the model III for the decay $B_s \rightarrow \gamma\gamma$

The LLog corrected effective Hamiltonian in the model III (see Appendix A) for the exclusive $B_s \rightarrow \gamma\gamma$ decay is

$$H_{eff} = \frac{-4G_F}{\sqrt{2}} v_{ts} v_{tb}^* \sum_i \left( C_i(\mu) O_i(\mu) + C_i'(\mu) O'_i(\mu) \right),$$

(1)

where the $O_i, O'_i$ are operators given in eqs. (41), (42), and $C_i, C'_i$ are the Wilson coefficients renormalized at the scale $\mu$. The Wilson coefficients $C_i$ and $C'_i$ can be calculated perturbatively and their explicit forms of at $m_W$ level are presented in Appendix B. The effective Hamiltonian (1) is obtained by integrating out the heavy degrees of freedom, i.e. $t$ quark, $W^\pm, H^\pm, H_1$, and $H_2$ bosons in the present case where $H^\pm$ denote charged, $H_1$ and $H_2$ denote neutral Higgs bosons. Further, QCD corrections are done through matching the full theory with the effective low energy theory at the high scale $\mu = m_W$ and evaluating the Wilson coefficients from $m_W$ down to the lower scale $\mu \sim O(m_b)$. In our case, we choose the higher scale as $\mu = m_W$ since the evaluation from the scale $\mu = m_{H^\pm}$ to $\mu = m_W$ gives negligible contribution to the Wilson coefficients ($\sim 5\%$) since the charged Higgs boson is heavy due to the current theoretical restrictions (see [14], [19]).

The decay amplitude for the $B_s \rightarrow \gamma\gamma$ decay is obtained by sandwiching the effective Hamiltonian between the $B_s$ and two photon states, i.e. $< B_s | H_{eff} | \gamma\gamma >$, and the matrix element can be written in terms of two Lorentz structures [4] - [6], [11]-[13]:

$$A(B_s \rightarrow \gamma\gamma) = A^+ F_{\mu\nu} \tilde{F}^{\mu\nu} + iA^- F_{\mu\nu} \tilde{F}^{\mu\nu},$$

(2)
where $\tilde{F}_{\mu \nu} = \frac{1}{2} \epsilon_{\mu \nu \alpha \beta} F^{\alpha \beta}$ and $A^+ (A^-)$ is the CP-even (CP-odd) amplitude. Denoting CP-even (CP-odd) amplitude coming from the first operator set eq. (11) as $A_1^+ (A_1^-)$ and the primed operator set eq. (12) as $A_2^+ (A_2^-)$, in a HQT inspired approach, we get,

$$A_1^+ = \frac{\alpha_{em} G_F f_{B_s} \lambda_t}{\sqrt{2\pi} m_{B_s}^2} \left( \frac{1}{3 \Lambda_s (m_{B_s} - \Lambda_s)} (m_b^{\text{eff}} + m_s^{\text{eff}}) C_7^{\text{eff}}(\mu) \right)
- \frac{4}{9} \frac{m_{B_s}^2 - m_s^{\text{eff}}}{m_b^{\text{eff}} + m_s^{\text{eff}}} \left[ (-m_b J(m_b) + m_s J(m_s)) D(\mu) - m_c J(m_c) E(\mu) \right],$$

$$A_1^- = -\frac{\alpha_{em} G_F f_{B_s} \lambda_t}{\sqrt{2\pi}} \left( \frac{1}{3 \Lambda_s (m_{B_s} - \Lambda_s)} \frac{1}{m_{B_s}} \frac{1}{m_{B_s}} \frac{1}{m_s} C_7^{\text{eff}}(\mu) \right) - \sum_q Q_q^2 I(m_q C_q(\mu))$$

and,

$$A_2^+ = \frac{\alpha_{em} G_F f_{B_s} \lambda_t}{\sqrt{2\pi} m_{B_s}^2} \left( \frac{1}{3 \Lambda_s (m_{B_s} - \Lambda_s)} (m_b^{\text{eff}} + m_s^{\text{eff}}) C_7^{\text{eff}}(\mu) \right),$$

$$A_2^- = -\frac{\alpha_{em} G_F f_{B_s} \lambda_t}{\sqrt{2\pi}} \left( \frac{1}{3 \Lambda_s (m_{B_s} - \Lambda_s)} \frac{1}{m_{B_s}} \frac{1}{m_s} C_7^{\text{eff}}(\mu) \right),$$

However, we do not take the CP-even and CP-odd amplitudes corresponding to the primed operator set since their contribution is small as compared to former ones (see [14, 20]). In eqs. (3) and (4), $Q_q = \frac{2}{3}$ for $q = u, c$ and $Q_q = -\frac{1}{3}$ for $q = d, s, b$. Here, we have used the unitarity of the CKM-matrix $\sum_{i=u,c,t} V_{i s} V_{i b} = 0$, and also the contribution due to $V_{u s} V_{u b} \ll V_{i s} V_{i b} \equiv \lambda_t$ is neglected. The function $g_-$ is defined as [11]:

$$g_- = m_{B_s} (m_b^{\text{eff}} + m_s^{\text{eff}})^2 \tilde{\Lambda}_s (m_{B_s}^2 - (m_b^{\text{eff}} + m_s^{\text{eff}})^2).$$

The parameter $\tilde{\Lambda}_s$ enters in eqs. (3) and (4) through the bound state kinematics (for details see [11]). In the expression (3), the LLog QCD corrected Wilson coefficients $C_{1...10}(\mu)$ [11] - [13] are,

$$C_u(\mu) = C_d(\mu) = (C_3(\mu) - C_5(\mu)) N_c + C_4(\mu) - C_6(\mu),$$

$$C_c(\mu) = C_1(\mu) + C_3(\mu) - C_5(\mu) N_c + C_2(\mu) + C_4(\mu) - C_6(\mu),$$

$$C_s(\mu) = C_6(\mu) = (C_3(\mu) + C_4(\mu))(N_c + 1) - N_c C_5(\mu) - C_6(\mu),$$

$$D(\mu) = C_5(\mu) + C_6(\mu) N_c,$$

$$E(\mu) = C_{10}(\mu) + C_9(\mu) N_c$$

and the effective coefficient $C_7^{\text{eff}}(\mu)$, defined in the NDR scheme, is [20]

$$C_7^{\text{eff}}(\mu) = C_{7}^{2HDM}(\mu) + Q_d \left( C_{5}^{2HDM}(\mu) + N_c C_{6}^{2HDM}(\mu) \right),$$

$$+ Q_u \left( \frac{m_c}{m_b} C_{10}^{2HDM}(\mu) + N_c \frac{m_c}{m_b} C_{9}^{2HDM}(\mu) \right)$$
where \( N_c \) is the number of colours (\( N_c = 3 \) for QCD). The functions \( I(m_q) \), \( J(m_q) \) and \( \Delta(m_q) \) come from the irreducible diagrams with an internal \( q \) type quark propagating and their explicit forms are given in Appendix D. In our numerical analysis we used the input values given in Table 1.

| Parameter  | Value                |
|------------|----------------------|
| \( m_c \)  | 1.4 (GeV)            |
| \( m_b \)  | 4.8 (GeV)            |
| \( \alpha_{em}^{-1} \) | 129                |
| \( \lambda_t \) | 0.04                |
| \( \Gamma_{tot}(B_s) \) | 4.09 \( \cdot 10^{-13} \) (GeV) |
| \( f_{B_s} \) | 0.2 (GeV)           |
| \( m_{B_s} \) | 5.369 (GeV)         |
| \( m_t \)  | 175 (GeV)            |
| \( m_W \)  | 80.26 (GeV)          |
| \( m_Z \)  | 91.19 (GeV)          |
| \( \Lambda_{QCD}^{(5)} \) | 0.214 (GeV)        |
| \( \alpha_s(m_Z) \) | 0.117               |
| \( \lambda_2 \) | 0.12 (GeV²)         |
| \( \lambda_1 \) | -0.29 (GeV²)        |
| \( \bar{\Lambda} \) | 590 (MeV)           |
| \( \bar{\Lambda} \) | 500 (MeV)           |

Table 1: Values of the input parameters used in the numerical calculations unless otherwise specified.

At this stage, we will calculate the \( CP \) violating asymmetry for the given process. The possible sources of such effects are the complex Yukawa couplings in the model III. Here, we neglect all the Yukawa couplings except \( \xi_{N,tt}^U \) and \( \xi_{N,bb}^D \) (see Section 3). Using the expressions for the decay amplitude

\[
\Gamma = \frac{1}{32\pi m_{B_s}} [4 |A^+|^2 + \frac{1}{2} m_{B_s}^4 |A^-|^2]
\]

and the \( CP \)-asymmetry

\[
A_{CP} = \frac{\Gamma(B_s \rightarrow \gamma\gamma) - \Gamma(\bar{B}_s \rightarrow \gamma\gamma)}{\Gamma(B_s \rightarrow \gamma\gamma) + \Gamma(\bar{B}_s \rightarrow \gamma\gamma)}
\]

we get

\[
A_{CP} = 2 Im(\lambda_\theta) \frac{8 Im(T_1^{(+)} T_2^{(+)*}) + m_{B_s}^4 Im(T_1^{(-)} T_2^{(-)*})}{\bar{D}}
\]
where

\[
T_1^{(+)} = aP_1 + \beta \quad T_2^{(+)} = aP_2 + b \quad T_1^{(-)} = cP_1 \quad T_2^{(-)} = cP_2 + d
\]  

(11)

and

\[
a = \frac{\alpha_{em}G_F f_{B_s}}{\sqrt{2\pi}} \frac{m_{B_s}^2}{3 \Lambda_s} \lambda_t \frac{(m_{t}^{eff} - m_{s}^{eff})}{(m_{B_s} - \Lambda_s)(m_{t}^{eff} + m_{s}^{eff})} \\
b = -\frac{\alpha_{em}G_F f_{B_s}}{\sqrt{2\pi}} \frac{4f_{B_s}}{9(m_{b}^{eff} + m_{s}^{eff})} \lambda_t [(-m_bJ(m_b) + m_sJ(m_s)]D(\mu) - m_cJ(m_c)E(\mu)] \\
c = -\frac{\alpha_{em}G_F f_{B_s}}{\sqrt{2\pi}} \frac{f_{B_s}}{3m_B\Lambda_s (m_{B_s} - \Lambda_s)} \lambda_t g_-
\]

\[
d = -\frac{\alpha_{em}G_F f_{B_s}}{\sqrt{2\pi}} \frac{f_{B_s}}{9(m_{b}^{eff} + m_{s}^{eff})}\lambda_t \sum_q (m_b\Delta(m_b) + m_s\Delta(m_s))D(\mu) + m_c\Delta(m_c)E(\mu)
\]  

(12)

In eq. (10), we used the parametrization,

\[
C_{eff}^{SM}(\mu) = P_1(\mu)\lambda_\theta + P_2(\mu)
\]  

(13)

with

\[
\lambda_\theta = \frac{1}{m_t m_b} |\bar{\xi}^{U}_{N,tt}\bar{\xi}^{D}_{N,bb}| e^{i\theta}
\]  

(14)

Here, \(\bar{\xi}^{U}_{N,tt}\) is chosen to be as real and \(\bar{\xi}^{D}_{N,bb}\) as complex, namely \(\bar{\xi}^{D}_{N,bb} = |\bar{\xi}^{D}_{N,bb}| e^{i\theta}\). Finally the functions \(P_1(\mu)\) and \(P_2(\mu)\), in the LLog approximation [21], are

\[
P_1(\mu) = \eta^{16/23} F_2(y) + \frac{8}{3}(\eta^{14/23} - \eta^{16/23})G_2(y) \\
P_2(\mu) = \eta^{16/23}[C_{7}^{SM}(m_W + \frac{|\bar{\xi}^{U}_{N,tt}|^2}{m_t^2} - F_1(y)] \\
+ \frac{8}{3}(\eta^{14/23} - \eta^{16/23})[C_{8}^{SM}(m_W + \frac{|\bar{\xi}^{U}_{N,tt}|^2}{m_t^2} - G_1(y)] \\
+ Q_d(C_5^{LO}(\mu) + N_cC_6^{LO}(\mu)) + Q_u(m_c/m_b C_{12}^{LO}(\mu) + N_c m_c C_{11}^{LO}(\mu)) \\
+ C_2(m_W) \sum_{i=1}^{8} h_i \eta^{\alpha_i}
\]  

(15)
and
\[ D = |\lambda_\theta|^2 \{ 8 |T_1^{(+)}|^2 + m_{B_s}^4 |T_2^{(-)}|^2 \} + 2 \text{Re}(\lambda_\theta) \{ 8 \text{Re}(T_1^{(+)}) T_1^{(-)*} \}
+ \text{Re}(\lambda_\theta) \} \{ 8 |T_2^{(+)})^2 + m_{B_s}^4 |T_2^{(-)}|^2 \} \] (16)

In eq. 15, \( \eta = \alpha_s(m_W)/\alpha_s(\mu) \) and \( h_i, a_i \) are numbers which appear during the evaluation of the Wilson coefficients [22].

Now, we would like to add the LD distance contributions due to the process \( B_s \to \phi \gamma \to \gamma \gamma \) [11]. These effects can be taken into account by the redefinition of the functions \( T_{1,2}^{(+, -)} \),
\[ T_{1,2}^{(+, -)} = T_{1,2}^{(+) + P a_{LD}} \] (17)
where
\[ a_{LD}^{(+)} = -\sqrt{2} \frac{\alpha_{em} G_F}{\pi} F_1(0) f_\phi(0) \lambda_i \frac{m_b}{3m_\phi} \]
\[ a_{LD}^{(-)} = \sqrt{2} \frac{\alpha_{em} G_F}{\pi} F_1(0) f_\phi(0) \lambda_i \frac{m_b}{3m_\phi} \] (18)
Note that there is also a LD contribution due to the chain process \( B_s \to \phi \psi \to \phi \gamma \to \gamma \gamma \) and it is negligible compared to the one due to the decay \( B_s \to \phi \gamma \to \gamma \gamma \) [23].

Finally, we derive the branching ratio for the given process as
\[ Br = \frac{1}{64 \pi m_{B_s} \Gamma_{tot}} \{ |\lambda_\theta|^2 \{ 8 |T_1^{(+)}|^2 + m_{B_s}^4 |T_2^{(-)}|^2 \} + 4 \text{Re}(\lambda_\theta) \{ 8 T_1^{(+)}) T_1^{(-)*} \}
+ m_{B_s}^4 T_2^{(-)*} T_2^{(-)*}) \} \{ 8 |T_2^{(+)})^2 + m_{B_s}^4 |T_2^{(-)}|^2 \} \] (19)

In the 3HDM(O2)(see Appendix C and [18]), the physical quantities under consideration are the same with the redefinition of \( \lambda_\theta \),
\[ \lambda_\theta = \frac{1}{m_t m_b} \bar{\epsilon}_{N, tt}^U \bar{\epsilon}_{N, bb}^D (\cos^2 \theta + i \sin^2 \theta) \] (20)

3 Discussion

In the model III, there are many parameters, such as complex Yukawa couplings, \( \xi_{U,D}^{i,j} \) (i,j are flavor indices), masses of charged and neutral Higgs bosons and they should be restricted using
experimental results. All the Yukawa couplings except $\xi_{N,tt}^U$ and $\xi_{N,bb}^D$ are cancelled based on the experimental measurements by CLEO [24],

$$Br(B \to X_s \gamma) = (3.15 \pm 0.35 \pm 0.32) \times 10^{-4},$$  \hspace{1cm} (21)

$\Delta F = 2$ mixing and the $\rho$ parameter [23] (see [20] for details). This discussion also allows us to neglect the contributions coming from the primed operator set. Further, the $CP$ parameter $"\theta"$, appearing in the combination $\bar{\xi}_{N,tt}^U \xi_{N,bb}^D = |\bar{\xi}_{N,tt}^U \xi_{N,bb}^D| e^{-i\theta}$, is restricted due to the experimental upper limit on neutron electric dipole moment $d_n < 10^{-25}$ e.cm, which gives an upper bound to the combination $\frac{1}{m_t m_b} Im(\bar{\xi}_{N,tt}^U \xi_{N,bb}^D) < 1.0$ for $m_H \approx 200$ GeV [26].

Now, we are ready to start with the discussion of $CP$ asymmetry in our process. Note that, in the analysis, $|C_{eff}^7|$ is allowed to lie in the region, $0.257 \leq |C_{eff}^7| \leq 0.439$ due to the CLEO measurement (see [20]) and the parameters $\bar{\xi}_{N,tt}^U$, $\bar{\xi}_{N,bb}^D$ and $\theta$ are restricted. We choose the scale as $\mu = m_b^2$ since we predict that this choice reproduce effectively the Next to Leading Order (NLO) result (see [11]).

In Fig 1(2), we plot the $A_{CP}$ of the decay $B_s \to \gamma \gamma$ with respect to $\sin \theta$, for $\xi_{N,bb}^D = 40 m_b$ and $m_{H^\pm} = 400$ GeV, in the case where the ratio $|r_{tb}| = \frac{|\bar{\xi}_{N,tt}^U \xi_{N,bb}^D|}{\xi_{N,bb}^D} < 1$, without (with) LD effects, in model III. $A_{CP}$ is restricted in the region bounded by solid (dashed) lines for $C_{eff}^7 > 0$ ($C_{eff}^7 < 0$). Figures show that $A_{CP}$ is at the order of $10^{-4}$, which is a weak effect. $A_{CP}$ is larger for $C_{eff}^7 > 0$, as compared to the $C_{eff}^7 < 0$ case and it is possible that $A_{CP}$ vanishes and even take negative values for $\sin \theta > 0$ and $C_{eff}^7 < 0$. Addition of LD effects enhances $A_{CP}$ small in amount.

Fig 3(4) denotes the same dependence of $A_{CP}$ for $3HDM(O_2)$ with (without) LD effects. The area of the restricted region and the possible values of $A_{CP}$ are smaller as compared to the 2HDM case. For example, for $\sin \theta = 0.5$ and $C_{eff}^7 > 0$, the upper limit of $A_{CP}$ decreases by an amount of 50%. However, the order of $A_{CP}$ still remains the same, namely $10^{-4}$. Furthermore, $A_{CP}$ is not sensitive to the charged Higgs boson mass $m_{H^\pm}$ (see Fig 5 and 6).

Figures 7-10 show the $Br$ of the given process for the model III and $3HDM(O_2)$. In Fig 4 (8), we present the dependence of $Br$ on $\sin \theta$ without (with) LD effects for $|r_{tb}| < 1$, in model III. The restricted region lies between solid (dashed) lines for $C_{eff}^7 > 0$ ($C_{eff}^7 < 0$). Note that $Br$ for $C_{eff}^7 < 0$ is greater than the one for $C_{eff}^7 > 0$. It is observed that the enhancement of $Br$ in the SM is negligible ($Br_{SM} = 3.45 \times 10^{-7}$ with LD effects and $Br_{SM} = 4.71 \times 10^{-7}$ without LD effects). Therefore model III can not be distinguished from the SM with the measurement of $Br$ of the given process, for $|r_{tb}| < 1$. Fig 8 and 10 denote the same dependence for $3HDM(O_2)$ and the results are similar to the 2HDM case.
Finally, in Fig 11, we plot the CP ratio $R = \left| \frac{A}{A^*} \right|$ with respect to $\sin \theta$ for 2HDM. Here, the solid line corresponds to $C_7^\text{eff} > 0$ and the dashed line to $C_7^\text{eff} < 0$. This figure shows that $R$ is not sensitive to CP violating parameter $\theta$ and there is a small enhancement compared to the SM value ($R_{SM} = 0.845$). This ratio is also non-sensitive to the models under consideration.

For completeness, we would like to note that there are some uncertainties coming from the choice of the bound state parameters $m_b^\text{eff}$, $\bar{\Lambda}_s$ and the decay constant $f_{B_s}$. The physical quantities are sensitive to these parameters. For example, the larger $m_b^\text{eff}$ (smaller $\bar{\Lambda}_s$), the larger $Br$, $R$ and the smaller $A_{CP}$.

In conclusion, we study the CP asymmetry of $B_s \to \gamma\gamma$ decay in the framework of the model III and 3HDM($O_2$). Further, we analyze the $Br$ and $R$ ratio of the given process. We can summarize the main points of our results:

- In model III, a weak $A_{CP}$ is possible and it is at the order of $10^{-4}$. This effect increases with the addition of LD contributions and this holds also in the 3HDM($O_2$) model. The measurement of such a small value of $A_{CP}$ can give information about the sign of $C_7^\text{eff}$.

- The $Br$ ratio is not sensitive to CP violation parameter $\theta$ and the enhancement as compared to SM is negligible in both models, for $|r_{tb}| < 1$

- The $R$ ratio is also non-sensitive to the parameter $\theta$ in both models.
A Appendix

Model III

The Yukawa interaction for the 2HDM in the general case is

\[ \mathcal{L}_Y = \eta_{ij}^U \bar{Q}_{iL} \tilde{\phi}_1 U_{jR} + \eta_{ij}^D \bar{Q}_{iL} \phi_1 D_{jR} + \xi_{ij}^U \bar{Q}_{iL} \tilde{\phi}_2 U_{jR} + \xi_{ij}^D \bar{Q}_{iL} \phi_2 D_{jR} + \text{h.c.}, \]  

(22)

where \( L \) and \( R \) denote chiral projections \( L(R) = 1/2(1 \mp \gamma_5) \), \( \phi_i \) for \( i = 1, 2 \), are the two scalar doublets, \( \eta_{ij}^{U,D} \) and \( \xi_{ij}^{U,D} \) are the matrices of the Yukawa couplings. With the choice of \( \phi_1 \) and \( \phi_2 \)

\[
\phi_1 = \frac{1}{\sqrt{2}} \left[ \begin{pmatrix} 0 \\ v + H^0 \end{pmatrix} + \begin{pmatrix} \sqrt{2} \chi^+ \\ i \chi_0 \end{pmatrix} \right]; \phi_2 = \frac{1}{\sqrt{2}} \begin{pmatrix} \sqrt{2} H^+ \\ H_1 + i H_2 \end{pmatrix},
\]

(23)

and the vacuum expectation values,

\[
< \phi_1 > = \frac{1}{\sqrt{2}} \begin{pmatrix} 0 \\ v \end{pmatrix}; \; < \phi_2 > = 0,
\]

(24)

we can write the Flavor Changing (FC) part of the interaction as

\[ \mathcal{L}_{Y, FC} = \xi_{ij}^U \bar{Q}_{iL} \tilde{\phi}_2 U_{jR} + \xi_{ij}^D \bar{Q}_{iL} \phi_2 D_{jR} + \text{h.c.}, \]

(25)

where the couplings \( \xi_{ij}^{U,D} \) for the FC charged interactions are

\[
\xi_{ch}^U = \xi_{neutral} V_{CKM},
\]

\[
\xi_{ch}^D = V_{CKM} \xi_{neutral},
\]

(26)

and \( \xi_{neutral} \) is defined by the expression

\[
\xi_{neutral}^{U,D} = (V_{L,R}^{U,D})^{-1} \xi_{neutral}^{U,D} V_{L,R}^{U,D}.
\]

(27)

Here, the charged couplings appear as a linear combinations of neutral couplings multiplied by \( V_{CKM} \) matrix elements.

B Appendix

3HDM(\( O_2 \))

In the 3HDM the general Yukawa interaction is,

\[
\mathcal{L}_Y = \eta_{ij}^U \bar{Q}_{iL} \tilde{\phi}_1 U_{jR} + \eta_{ij}^D \bar{Q}_{iL} \phi_1 D_{jR} + \xi_{ij}^U \bar{Q}_{iL} \tilde{\phi}_2 U_{jR} + \xi_{ij}^D \bar{Q}_{iL} \phi_2 D_{jR} + \rho_{ij}^U \bar{Q}_{iL} \tilde{\phi}_3 U_{jR} + \rho_{ij}^D \bar{Q}_{iL} \phi_3 D_{jR} + \text{h.c.},
\]

(28)

\footnote{In all next discussion we denote \( \xi_{neutral}^{U,D} \) as \( \xi_{N}^{U,D} \).}
where \( \phi_i \) for \( i = 1, 2, 3 \), are three scalar doublets and \( \eta_{ij}^{U,D} \), \( \xi_{ij}^{U,D} \), \( \rho_{ij}^{U,D} \) are the Yukawa matrices having complex entries, in general. Now, we choose scalar Higgs doublets such that the first one describes only the SM part and last two carry the information about new physics beyond the SM:

\[
\phi_1 = \frac{1}{\sqrt{2}} \left[ \begin{pmatrix} 0 \\ v + H^0 \end{pmatrix} + \begin{pmatrix} \sqrt{2} \chi^+ \\ i\chi^0 \end{pmatrix} \right],
\]

\[
\phi_2 = \frac{1}{\sqrt{2}} \begin{pmatrix} \sqrt{2}H^+ \\ H^1 + iH^2 \end{pmatrix}, \phi_3 = \frac{1}{\sqrt{2}} \begin{pmatrix} \sqrt{2}F^+ \\ H^3 + iH^4 \end{pmatrix},
\]

with the vacuum expectation values,

\[
<\phi_1> = \frac{1}{\sqrt{2}} \begin{pmatrix} 0 \\ v \end{pmatrix} ; <\phi_2> = 0 ; <\phi_3> = 0.
\]

Note that, the similar choice was done in the literature for the general 2HDM (model III) \cite{25}. The Yukawa interaction responsible for the Flavor Changing (FC) interactions is

\[
\mathcal{L}_{Y,FC} = \xi_{ij}^U \bar{Q}_i \tilde{Q}_j \phi_2 U^R_j + \xi_{ij}^D \bar{Q}_i \tilde{Q}_j \phi_2 D^R_j + \rho_{ij}^U \bar{Q}_i \tilde{Q}_j \phi_3 U^R_j + \rho_{ij}^D \bar{Q}_i \tilde{Q}_j \phi_3 D^R_j + h.c. .
\]

and the couplings \( \xi_{ij}^{U,D} \) and \( \rho_{ij}^{U,D} \) for the charged FC interactions are

\[
\xi_{ch}^U = \xi_N V_{CKM}, \\
\xi_{ch}^D = V_{CKM} \xi_N, \\
\rho_{ch}^U = \rho_N V_{CKM}, \\
\rho_{ch}^D = V_{CKM} \rho_N,
\]

and

\[
\xi_N^{U,D} = (V_L^{U,D})^{-1} \xi^{U,D} V_R^{U,D}, \\
\rho_N^{U,D} = (V_L^{U,D})^{-1} \rho^{U,D} V_R^{U,D},
\]

In the 3HDM model, the Higgs sector is extended and therefore the number of free parameters, namely, masses of new charged and neutral Higgs particles, new Yukawa couplings, increases. Fortunately, by introducing a new transformation in the Higgs sector and taking the 3HDM Lagrangian invariant under it, the number of free parameters can be reduced enormously \cite{18}. Taking the following \( O(2) \) transformation:

\[
\phi'_1 = \phi_1, \\
\phi'_2 = \cos \alpha \phi_2 + \sin \alpha \phi_3, \\
\phi'_3 = -\sin \alpha \phi_2 + \cos \alpha \phi_3,
\]
where \( \alpha \) is the global parameter, which represents a rotation of the vectors \( \phi_2 \) and \( \phi_3 \) along the axis where \( \phi_1 \) lies and assuming the invariance of the gauge and \( CP \) invariant Higgs potential

\[
V(\phi_1, \phi_2, \phi_3) = c_1(\phi_1^+ \phi_1 - v^2/2)^2 + c_2(\phi_2^+ \phi_2)^2 \\
+ c_3(\phi_3^+ \phi_3)^2 + c_4[(\phi_1^+ \phi_1 - v^2/2) + \phi_2^+ \phi_2 + \phi_3^+ \phi_3]^2 \\
+ c_5[(\phi_1^+ \phi_1)(\phi_2^+ \phi_2) - (\phi_1^+ \phi_2)(\phi_2^+ \phi_1)] \\
+ c_6[(\phi_1^+ \phi_1)(\phi_3^+ \phi_3) - (\phi_1^+ \phi_3)(\phi_3^+ \phi_1)] \\
+ c_7[(\phi_2^+ \phi_2)(\phi_3^+ \phi_3) - (\phi_2^+ \phi_3)(\phi_3^+ \phi_2)] \\
+ c_8[Re(\phi_1^+ \phi_2)]^2 + c_9[Re(\phi_1^+ \phi_3)]^2 + c_{10}[Re(\phi_2^+ \phi_3)]^2 \\
+ c_{11}[Im(\phi_1^+ \phi_2)]^2 + c_{12}[Im(\phi_1^+ \phi_3)]^2 + c_{13}[Im(\phi_2^+ \phi_3)]^2 + c_{14}
\]

(35)

we get the masses of new particles as

\[
m_{F^\pm} = m_{H^\pm} , \\
m_{H^3} = m_{H^1} , \\
m_{H^4} = m_{H^2} ,
\]

(36)

Further, the application of this transformation to the Yukawa Lagrangian eq.(28) allows us to write the equality

\[
(\xi^{U(D)})^+ \xi^{U(D)} + (\rho^{U(D)})^+ \rho^{U(D)} = (\xi^{U(D)})^+ \xi^{U(D)} + (\rho^{U(D)})^+ \rho^{U(D)} ,
\]

(37)

where

\[
\xi_{ij}^{U(D)} = \xi_{ij}^{U(D)} \cos \alpha + \rho_{ij}^{U(D)} \sin \alpha , \\
\rho_{ij}^{U(D)} = -\xi_{ij}^{U(D)} \sin \alpha + \rho_{ij}^{U(D)} \cos \alpha .
\]

(38)

and therefore the Yukawa matrices \( \xi^{U(D)} \) and \( \rho^{U(D)} \) can be parametrized as,

\[
\xi^{U(D)} = \epsilon^{U(D)} \cos \theta , \\
\rho^U = \epsilon^{U} \sin \theta , \\
\rho^D = i\epsilon^{D} \sin \theta .
\]

(39)

Here \( \epsilon^{U(D)} \) are real matrices satisfy the equation

\[
(\xi^{U(D)})^+ \xi^{U(D)} + (\rho^{U(D)})^+ \rho^{U(D)} = (\epsilon^{U(D)})^T \epsilon^{U(D)}
\]

(40)
and $T$ denotes transpose operation. Finally, we could reduce the number of the Yukawa matrices $\xi^{U(D)}$, $\rho^{U(D)}$, by connecting them with the expression given in eq. (39). Further, we take into account only the Yukawa couplings $\xi^{U}_{N,tt}, \xi^{D}_{N,bb}, \rho^{U}_{N,tt}$ and $\rho^{D}_{N,bb}$, since we assume that the others are small due to the discussion given in [20].

C Appendix

The operator basis and the Wilson coefficients for the decay $b \rightarrow s\gamma \gamma$ in the model III

The operator basis is the same as the one used for the $b \rightarrow s\gamma$ decay in the model III [20] and $SU(2)_L \times SU(2)_R \times U(1)$ extensions of the SM [27]:

\[
O_1 = (\bar{s}_L \gamma_\mu c_L \gamma_\mu b_L), \\
O_2 = (\bar{s}_L \gamma_\mu c_L \gamma_\mu b_L), \\
O_3 = (\bar{s}_L \gamma_\mu b_L) \sum_{q=u,d,s,c,b} (\bar{q}_{L,\beta} \gamma_\mu q_L), \\
O_4 = (\bar{s}_L \gamma_\mu b_L) \sum_{q=u,d,s,c,b} (\bar{q}_{L,\beta} \gamma_\mu q_L), \\
O_5 = (\bar{s}_L \gamma_\mu b_L) \sum_{q=u,d,s,c,b} (\bar{q}_{R,\beta} \gamma_\mu q_L), \\
O_6 = (\bar{s}_L \gamma_\mu b_L) \sum_{q=u,d,s,c,b} (\bar{q}_{R,\beta} \gamma_\mu q_L), \\
O_7 = \frac{e}{16\pi^2} \bar{s}_L \gamma_\mu b_L \sum_{q=u,d,s,c,b} (\bar{q}_{R,\beta} \gamma_\mu q_L), \\
O_8 = \frac{g}{16\pi^2} \bar{s}_L \gamma_\mu b_L \sum_{q=u,d,s,c,b} (\bar{q}_{R,\beta} \gamma_\mu q_L), \\
O_9 = \frac{e}{16\pi^2} \bar{s}_L \gamma_\mu b_L \sum_{q=u,d,s,c,b} (\bar{q}_{R,\beta} \gamma_\mu q_L), \\
O_{10} = \frac{e}{16\pi^2} \bar{s}_L \gamma_\mu b_L \sum_{q=u,d,s,c,b} (\bar{q}_{R,\beta} \gamma_\mu q_L), \\
\]

(41)

and the second operator set $O'_1 - O'_{10}$ which are flipped chirality partners of $O_1 - O_{10}$:

\[
O'_1 = (\bar{s}_R \gamma_\mu c_R \gamma_\mu b_R), \\
O'_2 = (\bar{s}_R \gamma_\mu c_R \gamma_\mu b_R), \\
O'_3 = (\bar{s}_R \gamma_\mu b_R) \sum_{q=u,d,s,c,b} (\bar{q}_{R,\beta} \gamma_\mu q_R), \\
O'_4 = (\bar{s}_R \gamma_\mu b_R) \sum_{q=u,d,s,c,b} (\bar{q}_{R,\beta} \gamma_\mu q_R), \\
O'_5 = (\bar{s}_R \gamma_\mu b_R) \sum_{q=u,d,s,c,b} (\bar{q}_{R,\beta} \gamma_\mu q_R), \\
\]

12
$$O'_6 = (s_{Ra} \gamma_\mu b_{R3}) \sum_{q=u,d,s,c,b} (\bar{q}_L \beta \gamma^\mu q_L),$$
$$O'_7 = \frac{e}{16\pi^2} s_{\alpha} \sigma_{\mu\nu} (m_b L + m_s R) b_\alpha F^{\mu\nu},$$
$$O'_8 = \frac{g}{16\pi^2} s_{\alpha} T^a_{\alpha\beta} \sigma_{\mu\nu} (m_b L + m_s R) b_\beta G^{a\mu\nu},$$
$$O'_9 = (s_{Ra} \gamma_\mu c_{R3})(\bar{c}_L \beta \gamma^\mu b_{L0}),$$
$$O'_{10} = (s_{Ra} \gamma_\mu c_{R3})(\bar{c}_L \beta \gamma^\mu b_{L\beta}),$$

(42)

where \(\alpha\) and \(\beta\) are \(SU(3)\) colour indices and \(F^{\mu\nu}\) and \(G^{a\mu\nu}\) are the field strength tensors of the electromagnetic and strong interactions, respectively. In the calculations, we take only the charged Higgs contributions into account and neglect the effects of neutral Higgs bosons (see [16] for details). Further, in our expressions we use the redefinition,

$$\xi^{U,D} = \sqrt{\frac{4G_F}{\sqrt{2}}} \xi^{U,D}. \quad (43)$$

Denoting the Wilson coefficients for the SM with \(C^{SM}_i(m_W)\) and the additional charged Higgs contribution with \(C^H_i(m_W)\), we have the initial values for the first set of operators (eq. (41)) (20 and references within)

\[
\begin{align*}
C^{SM}_{1,3,6,9,10}(m_W) &= 0, \\
C^{SM}_{2}(m_W) &= 1, \\
C^{SM}_{7}(m_W) &= \frac{3x^3 - 2x^2}{4(x - 1)^4} \ln x + \frac{-8x^3 - 5x^2 + 7x}{24(x - 1)^3}, \\
C^{SM}_{8}(m_W) &= -\frac{3x^2}{4(x - 1)^4} \ln x + \frac{-x^3 + 5x^2 + 2x}{8(x - 1)^3}, \\
C^{H}_{1,6,9,10}(m_W) &= 0, \\
C^{H}_{7}(m_W) &= \frac{1}{m_t^2} (\xi^{U}_{N,tt} + \xi^{U}_{N,tc} \frac{V_{ts}}{V_{ts}}) (\xi^{U}_{N,tt} + \xi^{U}_{N,tc} \frac{V_{ts}}{V_{tb}}) F_1(y), \\
&+ \frac{1}{m_t m_b} (\xi^{U}_{N,tt} + \xi^{U}_{N,tc} \frac{V_{ts}}{V_{ts}}) (\xi^{D}_{N,bb} + \xi^{D}_{N,ss} \frac{V_{ts}}{V_{tb}}) F_2(y), \\
C^{H}_{8}(m_W) &= \frac{1}{m_t^2} (\xi^{U}_{N,tt} + \xi^{U}_{N,tc} \frac{V_{ts}}{V_{ts}}) (\xi^{U}_{N,tt} + \xi^{U}_{N,tc} \frac{V_{ts}}{V_{tb}}) G_1(y), \\
&+ \frac{1}{m_t m_b} (\xi^{U}_{N,tt} + \xi^{U}_{N,tc} \frac{V_{ts}}{V_{ts}}) (\xi^{D}_{N,bb} + \xi^{D}_{N,ss} \frac{V_{ts}}{V_{tb}}) G_2(y), \quad (44)
\end{align*}
\]

and for the second set of operators eq. (12),

\[
\begin{align*}
C^{SM}_{1,10}(m_W) &= 0, \\
C^{H}_{1,6,9,10}(m_W) &= 0, \\
C^{H}_{7}(m_W) &= \frac{1}{m_t^2} (\xi^{D}_{N,bs} \frac{V_{tb}}{V_{ts}} + \xi^{D}_{N,ss}) (\xi^{D}_{N,bb} + \xi^{D}_{N,ss} \frac{V_{ts}}{V_{tb}}) F_1(y), \\
&+ \frac{1}{m_t m_b} (\xi^{D}_{N,bs} \frac{V_{tb}}{V_{ts}} + \xi^{D}_{N,ss}) (\xi^{D}_{N,bb} + \xi^{D}_{N,ss} \frac{V_{ts}}{V_{tb}}) F_2(y), \\
&+ \frac{1}{m_t m_b} (\xi^{D}_{N,bs} \frac{V_{tb}}{V_{ts}} + \xi^{D}_{N,ss}) (\xi^{D}_{N,bb} + \xi^{D}_{N,ss} \frac{V_{ts}}{V_{tb}}) G_1(y), \\
&+ \frac{1}{m_t m_b} (\xi^{D}_{N,bs} \frac{V_{tb}}{V_{ts}} + \xi^{D}_{N,ss}) (\xi^{D}_{N,bb} + \xi^{D}_{N,ss} \frac{V_{ts}}{V_{tb}}) G_2(y), \quad (45)
\end{align*}
\]
\[ C_{8}^{H}(m_{W}) = \frac{1}{m_{t} m_{b}} \left( \frac{\bar{\xi}_{N,bs} V_{tb}}{m_{t}} + \frac{\bar{\xi}_{N,ss}}{m_{b}} \right) (\bar{\xi}_{N,tt} + \frac{\bar{\xi}_{N,tc} V_{tb}}{m_{b}}) F_{2}(y) , \]

where \( x = m_{t}^{2}/m_{W}^{2} \) and \( y = m_{t}^{2}/m_{H^{\pm}}^{2} \). The functions \( F_{1}(y) \), \( F_{2}(y) \), \( G_{1}(y) \) and \( G_{2}(y) \) are given as

\[
\begin{align*}
F_{1}(y) & = \frac{y(7 - 5y - 8y^{2})}{72(y - 1)^{3}} + \frac{y^{2}(3y - 2)}{12(y - 1)^{4}} \ln y , \\
F_{2}(y) & = \frac{y(5y - 3)}{12(y - 1)^{2}} + \frac{y(-3y + 2)}{6(y - 1)^{3}} \ln y , \\
G_{1}(y) & = \frac{y(-y^{2} + 5y + 2)}{24(y - 1)^{3}} + \frac{-y^{2}}{4(y - 1)^{4}} \ln y , \\
G_{2}(y) & = \frac{y(y - 3)}{4(y - 1)^{2}} + \frac{y}{2(y - 1)^{3}} \ln y .
\end{align*}
\]

Note that we neglect the contributions of the internal \( u \) and \( c \) quarks compared to one due to the internal \( t \) quark. In the 3HDM\((O_{2})\) model, the Wilson coefficients are obtained with the replacement \( \bar{\xi}_{U}^{(D)} \to \bar{\xi}_{U}^{(D)} \) and the redefinition of \( \lambda_{\theta} \), \( \lambda_{\theta} = \frac{1}{m_{c} m_{b}} \bar{\xi}_{N,tt}^{D} \bar{\xi}_{N,bb}^{D}(\cos^{2} \theta + i \sin^{2} \theta) \).

For the initial values of the Wilson coefficients in the model III (eqs. (14) and (15)), we have

\[
\begin{align*}
C_{1,3,6,9,10}^{2HDM}(m_{W}) & = 0 , \\
C_{2}^{2HDM}(m_{W}) & = 1 , \\
C_{7}^{2HDM}(m_{W}) & = C_{7}^{SM}(m_{W}) + C_{7}^{H}(m_{W}) , \\
C_{8}^{2HDM}(m_{W}) & = C_{8}^{SM}(m_{W}) + C_{8}^{H}(m_{W}) , \\
C_{1,2,3,6,9,10}^{2HDM}(m_{W}) & = 0 , \\
C_{7}^{2HDM}(m_{W}) & = C_{7}^{SM}(m_{W}) + C_{7}^{H}(m_{W}) , \\
C_{8}^{2HDM}(m_{W}) & = C_{8}^{SM}(m_{W}) + C_{8}^{H}(m_{W}) .
\end{align*}
\]

At this stage it is possible to obtain the result for model II, in the approximation \( m_{t} / m_{b} \sim 0 \) and \( m_{t}^{2} / m_{t}^{2} \sim 0 \), by making the following replacements in the Wilson coefficients:

\[
\begin{align*}
\bar{\xi}_{st}^{U} & = \frac{1}{\tan^{2} \beta} , \\
\bar{\xi}_{st}^{D} & = -m_{t} m_{b} ,
\end{align*}
\]

and taking zero for the coefficients of the flipped operator set, i.e \( C_{i}^{f} \to 0 \).
The evaluation of the Wilson coefficients are done by using the initial values \( C_{i}^{2HDM(3HDM(O_2))} \) and their contributions at any lower scale can be calculated as in the SM case [20].

**D Appendix**

The necessary functions used in the Wilson coefficients

The explicit forms of the functions \( I(m_q) \), \( J(m_q) \) and \( \triangle(m_q) \) appearing in eqs. 3 and 4 are

\[
I(m_q) = 1 + \frac{m^2_q}{m_{B_s}^2} \triangle(m_q),
\]
\[
J(m_q) = 1 - \frac{m_{B_s}^2 - 4m_q^2}{4m_{B_s}^2} \triangle(m_q),
\]
\[
\triangle(m_q) = \left( \ln \left( \frac{m_{B_s} + \sqrt{m_{B_s}^2 - 4m_q^2}}{m_{B_s} - \sqrt{m_{B_s}^2 - 4m_q^2}} \right) - i\pi \right)^2 \text{ for } \frac{m_{B_s}^2}{4m_q^2} \geq 1,
\]
\[
\triangle(m_q) = -2 \arctan \left( \frac{\sqrt{4m_q^2 - m_{B_s}^2}}{m_{B_s}} \right) - \pi \right)^2 \text{ for } \frac{m_{B_s}^2}{4m_q^2} < 1. \quad (49)

Figure 1: $A_{CP}$ as a function of $\sin \theta$ for $\xi_{N_{bb}}^D = 40 m_b$ and $m_H^\pm = 400 \text{GeV}$ in the region $|r_{tb}| < 1$, at the scale $\mu = m_b/2$, without LD effects, in model III. Here $A_{CP}$ is restricted in the region bounded by solid lines for $C_7^{ef} > 0$ and by dashed lines for $C_7^{ef} < 0$. 
Figure 2: The same as Fig. 1 but with LD effects.

Figure 3: The same as Fig. 1 but for $3HDM(O_2)$ and $\tilde{\epsilon}_{N,bb}^D = 40 \text{ } m_b$. 
Figure 4: The same as Fig. 3 but with LD effects.

Figure 5: $A_{CP}$ as a function of $m_{H^\pm}$ for $sin \theta = 0.5$ and $\xi_{N,bb}^D = 40 m_b$ in the region $|r_{tb}| < 1$, at the scale $\mu = m_b/2$, with LD effects, in model III. Here $A_{CP}$ is restricted in the region bounded by solid lines for $C_7^{eff} > 0$ and by dashed lines for $C_7^{eff} < 0$. 
Figure 6: The same as Fig ??, but for 3HDM($O_2$) and $\xi_{N,bb}^D = 40 \, m_b$.

Figure 7: $Br$ as a function of $\sin \theta$ for $\xi_{N,bb}^D = 40 \, m_b$ and $m_{H^\pm} = 400 \, GeV$ in the region $|r_{tb}| < 1$, at the scale $\mu = m_b/2$, without LD effects, in model III. Here $Br$ is restricted in the region bounded by solid lines for $C_7^{\epsilon jj} > 0$ and by dashed lines for $C_7^{\epsilon jj} < 0$. 
Figure 8: The same as Fig 7, but with LD effects.

Figure 9: The same as Fig 7, but for $3HDM(O_2)$ and $\tilde{\epsilon}_{N,bb}^D = 40 m_b$. 
Figure 10: The same as Fig. 9, but with LD effects.

Figure 11: $R$ ratio as a function of $\sin \theta$ for $\bar{\xi}_{N,bb}^D = 40 m_b$ and $m_H^\pm = 400$ GeV in the region $|r_{tb}| < 1$, at the scale $\mu = m_b/2$, in model III. Here $R$ ratio is restricted on the solid (dashed) line for $C_7^{eff} > 0$ ($C_7^{eff} < 0$). Note that, for $3HDM(O_2)$, $R$ ratio is almost the same as the one calculated in model III.
