Background: Nonmelanoma skin cancer (NMSC) mainly includes basal (BCC) and squamous (SCC) cell carcinoma. Trophoblast cell-surface antigen2 (TROP2), a cell–signal transduction, is one of the tumor-related calcium signal transducer gene family. TROP2 was highly expressed in many cancers, however, its role in BCC and SCC has not yet been studied.

Objective: To investigate TROP2 immunohistochemical expression in BCC and SCC (lesional and peri-lesional) skin compared to controls and correlates its expression with the clinicopathologic parameters of the studied cases.

Methods: This case–control study included 17 BCC and 15 SCC patients as well as 12 age and sex matched controls. History and clinical examination were completed. Histological examination of skin biopsies was done together with TROP2 immune-staining.

Results: In the studied BCC and SCC cases, there was a significant stepwise up-regulation of TROP2 H score from control to peri-lesional, ended by lesional epidermis in one hand (p=0.003 for BCC and p=0.001 for SCC) and tumor island in another hand (p=0.001 for BCC and p=0.003 for SCC). TROP2 expression in both BCC and SCC tumor tissues was not affected by any of the studied clinicopathological parameters of the investigated cases.

Conclusion: TROP2 could have an important role in BCC and SCC pathogenesis. TROP2 targeting may have appraising effect in clinical application in BCC and SCC management.

Keywords: BCC, SCC, TROP2, clinical, immunohistochemical

Introduction

Nonmelanoma skin cancer (NMSC) refers to all the types of cancer that occur in the skin other than melanoma. It represents a wide disease spectrum ranging from low-risk to high-risk skin tumors. Numerous types of skin tumors are found within the category of NMSC, with the most common varieties being SCC and BCC. Incidence of the skin cancers are by far the most common of all types of cancer. Approximately 5.4 million SCC and BCC are diagnosed yearly in the United States and about 80% of them were BCCs. In Egypt, NMSC represents around 1.3% of all cancers, with BCC being more common than SCC.

BCC, the most common type of NMSC in humans, is characterized by a constantly increasing incidence with significant complications. It arises from the basal layer of the epidermis or appendages mostly on sun-exposed areas, especially head and neck, where most of lesions are of nodular morphology.

SCC, the second recorded common NMSC, is of keratinocyte origin. It involves the trunk and other body parts and is mainly categorized histologically as well, moderately or poorly differentiated.
The human TROP2 is a cell-surface glycoprotein that was described for the first time as a protein highly expressed on cell surface of trophoblasts. It consists of 323 amino acids and has extracellular domain, short transmembrane domain and a cytoplasmic tail.

TROP2 message is detected in many normal human tissues, including skin, suggesting its important function in ordinary situations. It has been implicated in numerous intracellular signaling pathways as transducing calcium signals. It can also activate extracellular signal regulated kinase (ERK) providing essential signals required for cell proliferation, survival and self-renewal. Additionally, TROP2 was reported to have stem cell-like abilities regulating cell growth, regeneration, transformation and proliferation. Furthermore, TROP2 has an ability to function as an adhesion molecule for epithelial cells, as its extracellular domain shares a conserved cysteine-rich region with epithelial-specific cell adhesion molecule.

In tumor cells, TROP2 has dual functions as it can act as tumor suppressor gene or an oncogene. Although it is down-regulated in cholangiocarcinoma, TROP2 was highly expressed in various human cancers as lung, cervix and oral SCC. Regarding BCC and cutaneous SCC, the role of TROP2 was not yet identified.

In this study, we tried to investigate the role of TROP2 in BCC and cutaneous SCC through evaluation of its immunohistochemical expression in lesional and peri-lesional skin of patients compared to healthy controls, in addition to, correlating this expression with the available clinicopathologic parameters in those patients.

Patients and Methods

This case–control prospective study included 44 subjects. They were 12 apparently healthy volunteers (controls group), 17 patients having BCC (45 to 80 years) and 15 cases having SCC (46 to 75 years). BCC and SCC patients were selected from Dermatology Outpatient Clinic, Menoufia University Hospital during the period between March 2018 and April 2019. The study protocol was approved by the Ethical Committee of Human Right of Research at Menoufia University (IRB approval number; 1001/7/4/2019DERM), that was in accordance with the Declaration of Helsinki. An informed written consent was signed by every participant before the study initiation.

We included newly diagnosed cases of BCC and SCC from both sexes. We excluded those who received any treatment for SCC or BCC in the past 6 months. Also, patients having any other skin diseases were excluded. The investigated controls were selected from those attending Plastic Surgery Clinic having no relevant skin diseases, and were age (44–70 years) and sex (9 males and 3 females) matched with the studied patients.

For the all cases, complete history taking and general examination were performed. Dermatological examination was done for the presenting lesion to assess its site, size and shape (mass or ulcer). In case of ulcers, we also examined the base, floor and edges of each one.

Skin biopsies, either incisional or excisional, were taken from lesional tissues of BCC and SCC patients and their peri-lesional tissues (0.5 cm away from the affected skin), and from matched sites of controls. The biopsies were sent to Pathology Department, faculty of Medicine, Menoufia University for routine tissue processing with paraffin-embedded blocks formation. From each block 4 μm thick sections were cut; one to be stained by haematoxylin and eosin (H&E) for diagnosis either BCC or SCC and evaluation of the tumor margins together with grade in SCC. Other sections were mounted on positive charged slides for immunohistochemical staining (one test slide and one negative control slide). The method used for immunostaining was streptavidin-biotin amplified system. The primary antibody was rabbit polyclonal antibody raised against TROP2. It was received as 0.1 mL concentrated with a dilution of 1:200 (Bioryt Ltd, Cambridge, United Kingdom Cat. orb1521). The detection Kit was the ultravision detection system anti-polyvalent horse radish peroxidase/diaminobenzidine (HRP/DAB) (Ready to use; Dako, Ref K8000, Glostrup, Denmark). A positive reaction was detected using DAB as a substrate-chromogen solution. Slides of normal prostate were used as a positive control for each run. Negative control slides were used for each run by omitting the primary antibody.

TROP2 was evaluated in epidermis and tumor islands of BCC and SCC cases and epidermis of peri-lesional and control tissues as follows: 1) Either positive or negative where positivity was considered by membranocyttoplasmic or cytoplasmic staining in any percentage of cells. 2) The intensity was graded subjectively and blindly by two pathologists independently, as mild, moderate and strong. 3) Histo-score (H score): was evaluated for studied cases as follows: H score = % of mild stained cells x1 + % of moderate stained cells x2 + % of strong stained cells x3.
Statistical Analysis
Data were collected, tabulated, and statistically analyzed using a personal computer with the “Statistical Package for the Social Sciences” (SPSS) version 20 program (SPSS Inc., Chicago, IL, US). Chi-square test was used for evaluation of qualitative data while Mann–Whitney, F-test (ANOVA), Kruskal–Wallis and Post Hoc (Dunn’s multiple comparisons) tests were used for evaluation of quantitative data. \( P < 0.05 \) was considered significant.

Results
Personal and Clinical Data of the Studied Subjects
The clinic-pathological data of the studied cases and controls are demonstrated in Table 1. BCC patients had age ranged from 45 to 80 years and 58.8% of them were males in comparison to 46 to 75 years and 80% males in SCC as well as 44 to 70 years and 75% males in controls with a non-significant difference between the studied groups regarding age (\( p = 0.105 \)), and sex (\( p = 0.415 \)).

TROP2 Immunostaining of the Studied Groups

In control group (Figure 1), TROP2 immunoreactivity was observed in epidermal keratinocytes of 9 cases (75%) having H score ranged from 20 to 80 with a mean ± SD of 38.89 ± 20.28.

In BCC cases (Figures 1 and 2), TROP2 was expressed in the lesional skin; overlying epidermis (13 cases, 76.5%) having H score ranged from 30 to 160 with a mean ± SD of 93.85 ± 43.50, and tumor islands (15 cases, 88.2%) where H score ranged from 30 to 210 and its mean ± SD was 109.33 ± 50.49. Peri-lesional tissues were available for 14 cases, TROP2 was expressed in overlying epidermis of 6/14 cases (42.9%) where H score ranged from 50 to 100 with 76.67 ± 19.66 as mean ± SD.

Regarding SCC cases (Figures 1 and 3), TROP2 was expressed in the lesional skin; overlying epidermis (11 cases, 73.3%) where H score mean ± SD was 140.91 ± 62.36 and tumor islands (14 cases, 93.3%) where H score mean ± SD was 94.29 ± 39.75. Peri-lesional tissues were available for 12 cases, TROP2 was expressed in overlying epidermis of 6/12 cases (50%) where H score range was 40 to 70 and the mean ± SD was 60.0 ± 15.49.

A significant difference was reported between the three studied groups (control, BCC and SCC) regarding TROP2 H scores in peri-lesional epidermis (0.012), lesional epidermis (<0.001) as well as tumor islands (0.002). However, comparing TROP2 expression and H scores in both BCC and SCC cases did not reveal any significant difference (Table 2).

Comparison between controls and BCC cases revealed a significant stepladder increase of TROP2 H score from control (38.89 ± 20.28) to BCC peri-lesional epidermis (76.67 ± 19.66) (p=0.018), ended by its highest values in

![Figure 1](https://doi.org/10.2147/CCID.S299862)

Figure 1 Mild positive membrano-cytoplasmic expression of TROP2 in epidermis of: (A) normal control and (B) BCC peri-lesional tissue. Moderate positive cytoplasmic expression of TROP2 in epidermis of: (C) BCC and (D) SCC (Immunoperoxidase ×400 for all).
BCC skin lesional epidermis (93.85 ± 43.50) (p=0.003) when the three groups are compared. A similar relationship were obtained on comparing tumor islands TROP2 H score (109.33 ± 50.49) with that of control and peri-lesional ones (p=0.001). Furthermore, both lesional epidermis and tumor islands showed a significantly higher H scores of TROP2 when each of them was compared to normal controls (p<0.001 and p=0.001, respectively) with a non-significant difference between both of them (p=0.141) (Table 3).

Similarly, the comparison between controls and SCC cases revealed a significant stepwise increase of TROP2 H score from control (38.89 ± 20.28) to SCC peri-lesional epidermis (60.0 ± 15.49) ended by SCC skin lesional epidermis (140.91± 62.36) (p<0.001) when the three groups are compared. A similar relationship were obtained on comparing tumor islands TROP2 H Score (94.29 ± 39.75) with that of control and peri-lesional ones (p=0.003). Additionally, both lesional epidermis and tumor islands showed a significantly higher H scores of TROP2 when each of them was compared to normal controls (p<0.001 and p=0.001, respectively) with a non-significant difference between both of them (p=0.109) (Table 4).

**Figure 2** Tumor islands of BCC showing; (A) negative, (B) mild positive, (C) moderate positive and (D) strong positive TROP2 expression (Immunoperoxidase x200 for A and C, x400 for B and D).

**Relationships Between TROP2 H Scores of Tumor Islands and Clinicopathological Parameters of BCC and SCC Patients**

TROP2 expression in both BCC and SCC tumor islands was not affected by any of the studied clinicopathological parameters of the investigated cases (data not shown).

**Discussion**

Although rarely fatal, BCC can be extremely destructive causing local tissue disfigurement particularly if treatment is
delayed or inadequate.\textsuperscript{27} Regarding SCC, the majority of head and neck cases require complicated surgery which can cause deformities\textsuperscript{28} with 10–18% local recurrence.\textsuperscript{29} Consequently, it is authoritative to determine biologic elements associated with BCC as well as SCC that may help in treatment.

TROP2, the know member of the tumor-related calcium transducer gene family,\textsuperscript{16} could be targeted to reduce its expression and, accordingly, to inhibit the tumor progression and decline its size. One human clinical trial, using IMMU-132 (the antibody conjugate), was under way for Phase I and II treatments of epithelial cancer cells expressing TROP2.\textsuperscript{30}

Herein, we tried to investigate, for the first time, if TROP2 has any association with BCC and/or SCC, through evaluation of its immunohistochemical expression in BCC and SCC patients compared to healthy controls.

The current work revealed a significant up-regulation of TROP2 H score in peri-lesional epidermis, lesional epidermis as well as tumor islands of BCC and SCC when compared to normal controls with a non-significant difference between both BCC and SCC groups. Furthermore, in each tumor, there was a significant step-ladder increase of TROP2 H score from control to peri-lesional epidermis, ended by skin lesional epidermis on one hand and with tumor islands on the other hand indicating an important function of TROP2 in both tumors’ development. Therefore, we proposed that, TROP2 might have a dynamic role in the pathogenesis of both BCC and SCC and subsequently, TROP2 targeting may have appraising effect in clinical application in BCC and SCC managing program.

Likewise, Stepan et al\textsuperscript{31} reported that TROP2 was expressed in various types of adenocarcinomas. As well, TROP2 overexpression was demonstrated in many human cancer cell types\textsuperscript{30} including SCC of the oral cavity.\textsuperscript{24,32,33}

Additionally, Nakashima et al\textsuperscript{34} recognized serum anti-
Table 2 Comparison Between the Studied Groups (Control, BCC and SCC) Regarding TROP2 Expression and H Score

TROP2 antibodies in cases having esophageal SCC. Also, they demonstrated significantly higher TROP2 expression in esophageal SCC than immunized and normal esophageal mucosa.

It was reported that over expression of TROP2 is associated with tumorigenesis and malignancy.35,36 TROP2 stimulates epithelial–mesenchymal transition through PI3K/AKT signaling, thus promoting cell proliferation and migration as well as tumor metastasis37 that was reported in gallbladder cancer38 and osteosarcoma cells.39 Additionally, TROP2 holds sites for tyrosine-serine phosphorylation that adjust signal transduction or its activity rendering tumor cell lines resistant to apoptosis.33 Furthermore, TROP2 signals through β-catenin40 that promotes the progression of tumors24 via suppressing tumor-infiltrating CD8+ T-cells41 which represent the major immune effector cells in antitumor immunity.42 Recently, in glioblastoma cells, it was reported that TROP2 is a regulator of JAK2/STAT3 signaling.43

In the current studied BCC and SCC cases, a non-significant difference exist between lesional epidermis and tumor islands TROP2 H scores (p=0.141 for BCC and p=0.109 for SCC), meanwhile, TROP2 H score of each of them was significantly higher than normal controls. Furthermore, the observed increased TROP2 H score of the studied BCC and SCC peri-lesional tissues was midway between its high values in BCC and SCC lesions, and low values of controls. These suggest that even apparently normal skin adjacent to/or covering BCC or SCC may harbor structural alterations at the cellular level. Supporting this result, Brakhuis et al44 reported that normal looking cells adjacent to malignant ones were genetically abnormal and were part of the transformed cells in the tumor field (skin field cancerization). These subclinical pre-neoplastic deviations are frequently present in skin that surrounds or covers the malignancy as fields of genetically cloned pre-neoplastic keratinocytes.45,46

The current study demonstrated over expression of TROP2 in BCC and SCC was not significantly affected by any of the studied clinicopathological parameters. In line with this result, Jiang et al22 reported that high TROP2 in oral SCC did not differ regarding patient age, gender and lymph node metastasis. Also, Tang et al24 revealed non-significant correlations between TROP2 expression and age, sex, tumor size, location and distant metastases.

On the other hand, Zhang et al25 reported a significant correlation of TROP2 with poorly differentiated oral SCC. Furthermore, TROP2 has been actively studied as a prognostic marker for various cancers including colon cancer and oral SCC.32,47 The difference between the results of aforementioned studies and ours could be attributed to the different types of the investigated tumors in each study.

Conclusions
Up-regulated TROP2 may actively participate in pathogenesis and development of both BCC and cutaneous SCC which open the door for its targeting as a new therapeutic modality with an appraising effect in BCC and SCC managing program.

Acknowledgment
We acknowledge the staff in Pathology Department, Faculty of Medicine, Menoufia University for their help and
providing us with the instruments necessary for completion of the work.

Funding
No sources of funding were used to conduct this study or prepare this manuscript.

Disclosure
The authors reported no conflicts of interest in this study.
