We study various semiclassical observables in the duality proposed by Guarino, Jafferis and Varela, between a warped $AdS_4 \times$ squashed $S^6$ gravitational solution and a 3 dimensional $\mathcal{N} = 2$ SYM-CS$_k$ conformal gauge theory, deformed from the maximal $SU(N)\mathcal{N} = 8$ SYM. Baryon vertices corresponding to particle-like branes have unusual behaviour with $N$ and $k$ and present strong evidence for a certain level-rank duality. Wilson loops and the anomalous dimensions of operators of high spin scale like $(N/k)^{3/2}$. The entanglement entropy behaves like in a usual CFT. Giant magnon operators obey the same law as in 4 dimensional $\mathcal{N} = 4$ SYM, and giant gravitons are also sub-determinant operators.

September 27, 2016
1 Introduction

The AdS/CFT correspondence has proved very successful in obtaining the nonperturbative properties of strongly coupled field theories. The best understood is the one originally studied by Maldacena, the duality of 4 dimensional $SU(N) \mathcal{N} = 4$ SYM vs. string theory in $AdS_5 \times S^5$, which has been used as a toy model for the physics of strong interactions, i.e. QCD [1]. On the other hand, in 3 dimensions, the best understood duality is of the ABJM model vs. string theory in $AdS_4 \times \mathbb{CP}^3$ background [2], which has been used as a toy model for 3 dimensional condensed matter systems. The ABJM model is an $\mathcal{N} = 6$ superconformal theory with gauge group $SU(N) \times SU(N)$ and Chern-Simons gauge fields, which is why it is more useful for condensed matter than for particle physics. In both SYM and ABJM cases a very large number of different types of calculations have been performed, due to the simplicity of the theories, yet in both the theories are very special (they are toy models), so the applicability of the lessons learned is unclear.

Recently however, a very interesting duality has been proposed in 3 dimensions by Guarino, Jafferis and Varela, between a fixed point of an $\mathcal{N} = 2$ supersymmetric $SU(N)$ SYM gauge theory with a Chern-Simons term of level $k$ added and string theory in a certain warped, squashed $AdS_4 \times S^6$ background of massive type IIA theory [3]. The theory is still superconformal, but has less supersymmetry, has an extra parameter $k$ that forms a 't Hooft coupling $\lambda = N/k$, and has both the SYM term interesting for particle physics and a CS term at level $k$ that as we will see can dominate the IR and imply a certain interesting level-rank duality. The theory arises as a deformation of the maximal $\mathcal{N} = 8$ $SU(N)$ SYM (with adjoint fields) on the worldvolume of $N$ D2-branes, and the resulting SCFT has been studied in [4].

The logic that led to the GJV solution was as follows. The four dimensional $\mathcal{N} = 8$ $SO(8)$-gauged supergravity [5] arises as a consistent truncation of 11 dimensional supergravity (low energy of M-theory) on the seven sphere [6, 7]. But it was pointed out in [8–10] that the original de Wit-Nicolai solution [5] is, in fact, just one particular point in a continuous one-parameter family of solutions, where the parameter $\omega \in [0, \pi/8]$ determines the linear combination of the $SO(8)$ electric and magnetic gauge fields. In this framework, the de Wit-Nicolai solution is purely electric and can be embedded into the $D = 11$ supergravity as a consistent truncation. These dyonic gaugings cannot be embedded in string/M-theory, as recently proved in [11]. A related symmetry group, namely the $ISO(7) = SO(7) \ltimes \mathbb{R}^7$, can be obtained from $SO(8)$ through a Inönü-Wigner contraction [12]. Solutions with this symmetry also admit dyonic gaugings [9], and it has been proved [13] that the purely electric solutions can be embedded into $D = 11$ supergravity as a consistent truncation on $S^6 \times S^1$. Moreover, the $ISO(7)$-dyonically gauged solution consid-
ered by GJV [3] arises as a consistent truncation of massive type IIA solution on a squashed 6-sphere, that we denote by $S^5$, and preserves up to $\mathcal{N} = 3$ supersymmetries [3,14–16]. The magnetic coupling constant $m$ is identified with the Romans mass $F_0$. In fact, this solution has fixed points that uplift to $\mathcal{N} = 2$ $AdS_4 \times S^5$. Since the internal space has the topology of a sphere, we expect that this solution arises as the near horizon geometry of a stack of $N$ D2-branes, with the Romans mass inducing a Chern Simons term on the brane worldvolume.\footnote{A related duality conjecture has been considered in [17], where the authors studied a stack of $D2$-branes probing a Calabi-Yau threefold singularity in the massive type IIA supergravity. In this case, the field theory is an $\mathcal{N} = 2$ Chern-Simons quiver gauge theory $U(N)^G$, where $G$ is the Euler number of the resolved manifold. The authors in [17] argued that in the low energy, the D2-brane theory flows to a modification (resolution) of the gravity dual $\mathcal{N} = 2$ $AdS_4 \times S^5$ of GJV [3].}

In this paper, we will study the GJV duality from the point of view of various observables associated with semiclassical string theory objects in the gravity dual. Static D-branes wrapped on cycles in the geometry correspond, if there are nontrivial tadpoles, to baryon vertices in the field theory, the (external) quarks corresponding to long strings that must end on the D-brane. Moving D-branes wrapped on cycles correspond to giant gravitons (gravitons that polarize into nontrivial D-branes in the geometry), and correspond to certain subdeterminant operators. Long strings in the geometry can give Wilson loops, the anomalous dimension of high spin operators and giant magnon spin chain operators.

The paper is organized as follows. In section two we review the GJV solution, perform the quantization of the charges, and review the dual field theory. In section 3 we study D-branes on cycles and their gravity duals: baryon operators for the static branes and determinant operators for moving branes, i.e. giant gravitons, as well as the gauge coupling on the wrapped branes. In section 4 we study entanglement entropy from the holographic prescription. In section 5 we study strings in the geometry, giving Wilson loops and the anomalous dimension of operators of large spin. In section 6 we study giant magnons from the point of view of both gravity and field theory, and in section 7 we conclude.

## 2 Guarino-Jafferis-Varela solution and duality to SYM-CS

In [3] the authors showed that a consistent truncation of a massive type IIA SUGRA on the six sphere $S^6$ gives rise to the $ISO(8)$-dyonically-gauged SUGRA with the magnetic coupling constant related to the Romans mass. They also showed that this supergravity solution has a fixed point which uplifts to a new $\mathcal{N} = 2$ $AdS_4 \times S^5$.
solution, where $SS^5$ is the suspension of $S^5$ and is topologically equivalent to the six sphere $S^6$ [17].

The fixed point solution [3, 17] has metric (in the Einstein frame and the conventions of [18])

$$ds_{IIA}^2 = \Delta \left\{ ds_{AdS^4}^2 + \frac{3}{2} d\alpha^2 + \Xi ds_{\mathbb{C}P^2}^2 + \Omega \eta^2 \right\}$$

(2.1a)

where $\Delta = L^2 (3 + \cos 2\alpha)^{1/2} (5 + \cos 2\alpha)^{1/8}$, $\Xi = 6 \sin^2 \alpha / (3 + \cos 2\alpha)$, $\Omega = 9 \sin^2 \alpha / (5 + \cos 2\alpha)$ and $\alpha \in [0, \pi]$. Also $\eta = d\psi + \omega$, where $\psi \in [0, 2\pi]$ and $\mathcal{J} = \frac{1}{2} d\omega$ is the Kähler-form of $\mathbb{C}P^2$. We write the warp factor in string frame as

$$L_{\text{string}}^2 = e^{\phi/2} \Delta = L^2 e^{\phi_0/2} (5 + \cos 2\alpha)^{1/2}.$$  

(2.1b)

The determinant of the internal manifold metric

$$ds_{SS^5}^2 = \frac{3}{2} d\alpha^2 + \Xi ds_{\mathbb{C}P^2}^2 + \Omega \eta^2$$

(2.1c)

is

$$\det(G_{SS^5}) = \frac{3 \Xi^4 \Omega}{128} \sin^3 \theta \sin^6 \lambda \cos^2 \lambda.$$  

(2.1d)

In addition, in the internal manifold we have, for fixed $\psi$ and $\alpha$ (with $\alpha \neq 0, \pi$ to avoid the isolated conical singularities), a $\mathbb{C}P^2$ space, and for $\lambda = \pi/2$ and fixed $\sigma$ we have a $\mathbb{C}P^1$.

The solution contains the NS-NS fields

$$e^\phi = e^{\phi_0} \frac{(5 + \cos 2\alpha)^{3/4}}{(3 + \cos 2\alpha)}$$

(2.1e)

$$H_3 = 24 \sqrt{2} L^2 e^{\phi_0/2} \frac{\sin^3 \alpha}{(3 + \cos 2\alpha)^2} \mathcal{J} \wedge d\alpha$$

(2.1f)

in the NS-NS sector. For later convenience, we write $e^\phi \equiv g_s^\alpha$, $e^{\phi_0} \equiv g_s$ and $\gamma(\alpha) \equiv \frac{(5 + \cos 2\alpha)^{3/4}}{(3 + \cos 2\alpha)}$. With this notation, equation (2.1e) becomes

$$g_s^\alpha = g_s \gamma(\alpha).$$

(2.1g)

We note that the string coupling $g_s^\alpha$ is maximum at $\alpha = \pi/2$ and minimum at $\alpha = 0, \pi$ (its derivative with respect to $\alpha$ is positive on the interval $[0, \pi/2]$ and negative on the interval $[\pi/2, \pi]$).
The RR fields are
\[
\tilde{F}_0 = 3^{-1/2} L^{-1} e^{-5\phi_0/4} \equiv m
\]
\[
\tilde{F}_2 = -\sqrt{6} L e^{-3\phi_0/4} \left\{ \frac{4 \sin^2 \alpha \cos \alpha}{(3 + \cos 2\alpha)(5 + \cos 2\alpha)} J + \frac{3(3 - \cos 2\alpha)}{(5 + \cos 2\alpha)^2} \sin \alpha \, d\alpha \wedge \eta \right\}
\]
\[
\tilde{F}_4 = -\sqrt{6} L e^{-3\phi_0/4} \left\{ \frac{4 \sin^2 \alpha \cos \alpha}{(3 + \cos 2\alpha)(5 + \cos 2\alpha)} J - d \left( \frac{3 \cos \alpha}{5 + \cos 2\alpha} \right) \wedge \right\}
\]
\[
\tilde{F}_4 = L^3 e^{-\phi_0/4} \left\{ 6 \text{vol}(AdS_4) + 12 \sqrt{3} \frac{(7 + 3 \cos 2\alpha)}{(3 + \cos 2\alpha)^2} \sin^4 \alpha \, vol(CP^2)
\]
\[
+ 18 \sqrt{3} \frac{(9 + \cos 2\alpha)}{(3 + \cos 2\alpha)(5 + \cos 2\alpha)} J \wedge d\alpha \wedge \eta \right\}
\]
in the R-R sector. Finally, the constants are
\[
L^2 \equiv 2^{-5/8} 3^{-1} g^{-25/12} m^{1/12} \quad \text{and} \quad e^{\phi_0} \equiv 2^{1/4} g^{5/6} m^{-5/6}.
\]
2.1 Quantization of charges

We can consider the most appropriate flux in a supergravity background by the so-called, Page charges [20], defined as follows. Consider the $d$-closed $p$-form defined as

$$\hat{F}_p := \left[ e^{-B} \wedge (\tilde{F}_0 + \tilde{F}_2 + \tilde{F}_4 + \tilde{F}_6 + \tilde{F}_8) \right]_p. \quad (2.7)$$

Then the Page charges $N_k \in \mathbb{Z}$ are defined by

$$n_p := \frac{1}{(2\pi \ell_s)^{p-1}} \int_{\Sigma^p} \hat{F}_p, \quad (2.8)$$

where $\Sigma^p$ is a closed space-like $p$-cycle and $\ell_s = \sqrt{\alpha'}$. In particular,

$$k \equiv n_0 = 2\pi \ell_s F_0 = 2\pi \ell_s m. \quad (2.9)$$

is an integer that has a simple interpretation in the field theory as a CS level. In the solution considered in the last section, we have, on a 6-cycle (the whole compact space)

$$N \equiv n_6 = \frac{1}{(2\pi \ell_s)^5} \int_{S^5} \left( \tilde{F}_{(6)} - B \wedge dC_{(3)} - \frac{\tilde{F}_{(0)}}{6} B \wedge B \wedge B \right), \quad (2.10)$$

where $\tilde{F}_{(6)} = -e^{\phi/2} \ast \tilde{F}_4$, and the Hodge dual is taken with relation to the Einstein frame metric (2.1a), as the authors of [3] have shown. This integer will correspond to the rank of the gauge group in the field theory. In fact, these are the quantized charges that we have associated to the massive supergravity above, and the quantization of the fluxes implies that

$$L = \left( \frac{2^{43/2} \pi^9}{3^{22}(4 - \pi)^5} \right)^{1/24} k^{1/24} N^{5/24} \ell_s; \quad e^{\phi_0} = \frac{2^{11/6} 3^{1/3} \pi^{1/2} (4 - \pi)^{1/6}}{k^{5/6} N^{1/6} \ell_s \sqrt{5 + \cos 2\alpha}}. \quad (2.11)$$

The reader should compare the two expressions with those obtained in [17], where the authors considered the round sphere for the internal manifold.

Note that

$$L_{\text{string}} e^{\phi_0} = \frac{2\pi \ell_s}{\sqrt{3k}} [5 + \cos 2\alpha]^{1/4} \Rightarrow L_{\text{string}} g_\alpha^s = \frac{2\pi \ell_s}{k} \frac{5 + \cos 2\alpha}{\sqrt{3 + \cos 2\alpha}}. \quad (2.12)$$

In [20], the author showed that there are three distinct notions of charges associated to a given gauge field, namely, Brane charges, Maxwell charges and Page charges, and only the latter is quantized, as we have seen above.
Consider, for example, the 4-form field strength \( \tilde{F}_4 = dC_3 + C_1 \wedge H_3 + \frac{F_2}{2} B \wedge B \), that satisfies the Bianchi identity \( d\tilde{F}_4 = H_3 \wedge \tilde{F}_2 \). The first type of charge is given by the integral over the space \( \mathcal{M}^5 \) such that \( \partial \mathcal{M}^5 = \Sigma^4 \) of the current
\[
\star \mathcal{J}_{D4} = d\tilde{F}_4 - H_3 \wedge \tilde{F}_2 ,
\] (2.13a)
that is
\[
Q_{D4} = \frac{1}{8\pi^3 \alpha'^3/2} \int_{\mathcal{M}^5} \star \mathcal{J}_{D4} ,
\] (2.13b)
and this charge is gauge invariant but it is not quantized.

Similarly, we can define charges\(^2\) for the D2-branes and D6-branes, through the following currents
\[
\star \mathcal{J}_{D6} = d\tilde{F}_2 - \tilde{F}_0 H_3 \quad \Rightarrow \quad Q_{D6} = \frac{1}{2\pi \alpha'^{1/2}} \int_{\mathcal{M}^3} \star \mathcal{J}_{D6} ,
\] (2.14a)
\[
\star \mathcal{J}_{D2} = d\tilde{F}_6 - H_3 \wedge \tilde{F}_4 \quad \Rightarrow \quad Q_{D2} = \frac{1}{32\pi^5 \alpha'^{5/2}} \int_{\mathcal{M}^7} \star \mathcal{J}_{D2} ,
\] (2.14b)
where \( \tilde{F}_6 = - \star \tilde{F}_4 \).

We can define another important charge by regarding the right hand side of the equation
\[
d\tilde{F} = H_3 \wedge \tilde{F}
\] (2.15a)
as a source for the field strength \( \tilde{F} \), so that
\[
d\tilde{F}_{8-p} = \star \mathcal{J}_{Dp}^{Maxwell} .
\] (2.15b)
Integrating this equation and using the Stokes theorem, with the appropriate normalization, we find
\[
Q_{Dp}^{Maxwell} = \frac{1}{(2\pi \ell_s)^{7-p}} \int_{\Sigma^{7-p}} \tilde{F}_{8-p} .
\] (2.15c)

In the Guarino-Jafferis-Varela (GJV) solution, we can easily see that
\[
n_6 = Q_{D2}^{Maxwell} - \frac{1}{(2\pi \ell_s)^5} \int_{SS^5} \left( B \wedge dC_{(3)} + \frac{\tilde{F}_{(0)}}{6} B \wedge B \wedge B \right)
\] (2.16)
and since the additional terms vanish trivially, we find that the Maxwell charge is identical to the Page charge, that is \( Q_{D2}^{Maxwell} = N \).

Under this perspective, there is one more relevant cycle we may consider in the GJV solution, namely, the 4-cycle parametrized by the coordinates \( \Sigma^4 = (\lambda, \theta, \phi, \sigma) \). We can easily see that this cycle is the \( \mathbb{CP}^2 \) metric multiplied by the factor \( e^{\phi/2} \Delta \Xi \)

\(^2\)Defined as \( (2\pi \ell_s)^{7-p} Q_{Dp} = \int_{\mathcal{M}^5} \star \mathcal{J}_{Dp} \).
that vanishes at the points $\alpha = 0, \pi$, and since $\tilde{F}_4 |_{\Sigma^4}$ also vanishes at these points, we conclude that the Page charge $n_4$ is zero in this cycle. On the other hand, the Maxwell charge is not trivial, that is

$$Q^{\text{Maxwell}}_{D4} = \frac{1}{(2\pi \ell_s)^3} \int_{\Sigma^4} \tilde{F}_4$$

$$= \frac{3\sqrt{3}}{8\pi} \frac{L^3 e^{-\phi_0/4} (7 + 3 \cos 2\alpha)}{\ell_s^3 (3 + \cos 2\alpha)^2} \sin^4 \alpha. \quad (2.17)$$

Furthermore, the Page charges are well defined up to a large gauge transformations, that shifts the Kalb-Ramond flux

$$b = \frac{1}{2\pi \ell_s} \int_{\Sigma^2} B$$

by an integer. In fact, since $d\tilde{F}_2 = \tilde{F}_0 H_3$, we can write

$$B = \frac{\tilde{F}_2}{\tilde{F}_0} + B,$$  

where $B = -dC_1/\tilde{F}_0$ and we can easily verify that $\tilde{F}_0 B = -\tilde{F}_2$, so in principle it should be quantized, but once we consider a 2-cycle $\Sigma^2$ with legs in the coordinate $\alpha$, the integral $\int_{\Sigma^2} dC_1$, vanishes trivially, as well as the Maxwell charge associated to this cycle [21–24]. In particular, we can write the Kalb-Ramond flux as

$$b = \frac{2\pi \ell_s}{n_0} \left( n_2 + Q^{\text{Maxwell}}_{D6} \right), \quad (2.20)$$

and if the Maxwell charge $Q^{\text{Maxwell}}_{D6}$ vanishes, the flux $b$ goes with $n_2/n_0$.

### 2.2 Field theory dual

The field theory dual to this gravitational solution was proposed to be the maximal $\mathcal{N} = 8$ SYM theory in 2+1 dimensions with a single gauge group $SU(N)$, the $N$ corresponding to the integer in the quantized flux on $S^6$ (the Page charge $n_6$ of the previous subsection), deformed by Chern-Simons terms with level $k$ related to the mass parameter $m$ by the relation

$$m = \frac{k}{2\pi \ell_s}. \quad (2.21)$$

As we saw, $k$ is the same as the Page charge $n_0$ of the previous subsection.

The field theory has 7 adjoint scalars (corresponding to the 7 transverse coordinates to the 2+1 dimensional worldvolume in 10 dimensional string theory), and
8 fermions transforming under the R-symmetry group $SO(7)$. At low energy, an adjoint scalar dual to a photon completes the fundamental representation of the full $SO(8)$ R-symmetry group.

The addition of the Chern-Simons term

$$\frac{k}{4\pi} \text{Tr} \left[ A \wedge F + \frac{2}{3} A \wedge A \wedge A \right],$$

(2.22)
together with additional couplings, can preserve $\mathcal{N} = 2$ supersymmetry, like the gravitational solution. The SYM theory in 3 dimensions has a dimensionful coupling, but the theory flows in the IR to a fixed point with conformal symmetry, corresponding to the warped $AdS_4$ factor in the gravity dual. In this fixed point, the effective 't Hooft coupling is

$$\lambda = \frac{N}{k},$$

(2.23)

which must be $\gg 1$ for the supergravity approximation to hold in the gravity dual. Indeed, the curvature in string units is large only if $N/k \gg 1$, as can be see from (2.11).

In $\mathcal{N} = 2$ notation, we have an adjoint vector multiplet (that contains a real scalar and a complex fermion) and 3 chiral multiplets with complex scalars $Z, W, T$, like the dimensional reduction of the 3+1 dimensional $\mathcal{N} = 4$ SYM, with the same superpotential,

$$W = \text{Tr} (Z[W, T]).$$

(2.24)

The theory has R-symmetry $U(1) \times SU(3)$, with $SU(3)$ rotating the 3 complex scalars in the chiral multiplets.

The symmetries correspond to the symmetries of the gravity solution. The would-be $SO(7)$ symmetry of the $S^6$ is also broken by the squashing/fibration to $SU(3)$, acting on $\mathbb{C}P^2$, times $U(1)$, translating $\psi$, or rather $\eta$.

## 3 Particle-like branes and their field theory duals

In this section we consider branes wrapped on cycles, that look like particles from the point of view of the field theory, and their dual interpretation. We will study static D-branes and moving D-branes.

The D-brane action is inversely proportional to the string coupling. If $g_s$ would get large, we would have light D-brane states. But in fact, in [25], the authors argued that massive type IIA theory cannot be strongly coupled. In the examples considered in their work, the authors showed that the string coupling $g_s$ has two regimes. In
the first regime, $g_s$ increases with $N$ as usual in the massless theories, but then it reaches a second regime where it decreases for large $N$.

In the GJV solution, we can easily prove that there is no such phase transition, since the coupling $g_s^\alpha$ remains bounded,

$$g_s^\alpha = e^\phi \sim \frac{1}{k^{5/6}N^{1/6}} < \frac{\ell_s}{L_{\text{string}}}, \quad \forall \, N, k,$$

(3.1)

where from (2.11), $L_{\text{string}} \sim N^{1/6}k^{-1/6}\ell_s$ (see also (2.12)), and moreover as we said, must be taken to be $\gg \ell_s$ for validity of the supergravity approximation, by imposing $N \gg k$.

### 3.1 Branes on cycles in the GJV geometry

In this subsection we consider static branes, that will correspond to solitonic operators in the dual field theory.

We can write the action for a general $D_p$-brane as the sum of the DBI term and a WZ term,

$$S_{D_p} = -T_{D_p} \int d^{p+1}\xi e^{-\phi} \sqrt{-\det(G + F)} - T_{D_p} \int \sum_{\tilde{p}} C_{\tilde{p}} \wedge e^\tilde{F},$$

(3.2)

where $F = B + 2\pi\alpha' F$ and $T_{D_p} = (2\pi)^p \ell_s^{p+1}$. It has been shown in [26] that in the presence of Romans mass, we need to add the WZ term for $F_0$,

$$S_{m}^{D_p} = T_{D_p}F_0 \int \sum_{r=0} \left(2\pi\alpha'\right)^r \frac{\omega^r_{2r+1}}{(r+1)!} \bigg|_{p+1},$$

(3.3)

$$= \frac{kT}{(2\pi)^p\alpha'^p/2} \int \sum_{r=0} \left(2\pi\alpha'\right)^r \frac{\omega^r_{2r+1}}{(r+1)!} \bigg|_{p+1},$$

where $\omega^r_{2r+1}$ is a Chern-Simons form, such that $d\omega^r_{2r+1} = \text{tr}(F)^{r+1} \Rightarrow \omega^r_{2r+1} = \text{tr}(A \wedge F^r)$, and in the second expression we have used that $F_0 = n_0 T \sqrt{\alpha'} \equiv kT \sqrt{\alpha'}$, where $T = 1/(2\pi\alpha')$ is the string tension and $F = dA$. We consider just an abelian ($U(1)$) field strength $F$.

**D0-branes**

We start with the analysis of D0-branes, which therefore need not be wrapped on cycles, since they are already particle-like. The D0 brane action develops a tadpole from the WZ term (3.3), namely

$$S_{m}^{D_0} = -T_{D_0}F_0 \int_{\mathbb{R}} dt A_t = -n_0 T \int dt A_t.$$

(3.4)
That means that we need to add $k$ fundamental strings ending on the D0-brane. In principle, there is also the leading term in the WZ part, $\int_\Sigma C_1$, but since $C_1$ has no component along $dt$, corresponding to $\Sigma = R_t$, for a static D0-brane as we consider here, this contribution vanishes.

Moreover, from the DBI action

$$S_{DBI} = -T_{D0} \int_R dt \ e^{-\phi} \sqrt{|G_{tt}|},$$

we easily see that the brane mass is

$$M_{D0}(\alpha) = \frac{T_{D0}}{g_s^{\alpha}} \sim T_{D0}(Nk^5)^{1/6}\gamma(\alpha)^{-1}. \quad (3.6)$$

Since as we saw, the string coupling $g_s^{\alpha}$ is maximal at $\alpha = \pi/2$, where it takes the value $e^{\phi_0}/\sqrt{2}$, the D0-brane will stabilize at this value of $\alpha$, that minimizes its energy, giving

$$M_{D0} = T_{D0}k \left( \frac{N}{k} \right)^{1/6} \frac{(4 - \pi)^{1/6}}{2 \cdot 3^{1/3} \sqrt{\pi}}. \quad (3.7)$$

In conclusion, this D0-brane needs $k$ fundamental strings to end on it.

**D6-branes**

The D6-brane wrapping the whole internal space $SS^5$ develops a tadpole due to the WZ coupling

$$S^{WZ}_{D6} = -T_{D6} \int_{R \times SS^5} \tilde{F}_6 \wedge A = -NT \int_R dt A_t, \quad (3.8)$$

thus we need $N$ fundamental strings ending on this brane. The leading WZ coupling for the D6-brane would come from $C_7$ integrated over the compact space, where $\tilde{F}_8 = dC_7 - H_3 \wedge C_5 + ... = -e^{\phi/2}\tilde{F}_2$, but since $\tilde{F}_2$ has only components in the compact dimensions, $\tilde{F}_8$ is nonzero only when it has at least two non-compact directions. The same is true for the terms $H_3 \wedge C_5 + ...$, which means that the integral of $C_7$ over the compact space and time is zero.

The mass of the D6-brane is then given by

$$M_{D6} = T_{D6} \int d^6 \xi e^{-\phi} \sqrt{G_6} = \sqrt{\frac{3}{2}} \pi^{3/2} T_{D6} \int_0^\pi d\alpha \sqrt{\Omega \Xi^2 L_6^{string}} e^\phi \sim (T_{D6}\alpha'^3)^{N^{7/6}}k^{1/6}, \quad (3.9)$$

---

3Given a static D$p$-brane wrapping a $p$-cycle $\Sigma$ with a vanishing WZ term, its mass is given by the DBI term, $M_{Dp} = T_{Dp} \int_\Sigma g_s^{-1} \sqrt{\det_\Sigma(G + \mathcal{F})}$, where $\det_\Sigma$ means the determinant along the $p$-cycle $\Sigma$. 

11
where $G_6$ is the determinant of the internal manifold in (2.1a). More precisely, one obtains (also taking into account that $T_{D6}(2\pi\sqrt{\alpha'})^6 = T_{D6}$)

$$M_{D6} = T_{D6}N \left( \frac{N}{k} \right)^{1/6} \frac{2^{1/12}3^{1/6}}{6\sqrt{\pi}(4 - \pi)^{7/6}} \int_0^\pi d\alpha \sin^5 \alpha \frac{(5 + \cos 2\alpha)^{1/4}}{3 + \cos 2\alpha}. \quad (3.10)$$

An observation about the calculation in (3.9) is that the warp factor $L_{\text{string}}$ is $\alpha$-dependent, and since we still have one factor $L_{\text{string}}$ from the component $G_{tt}$ in the metric, the Dirac-Born-Infeld is not the product of (3.9) and the time integration of $\sqrt{G_{tt}}$.

**Bound state of D0-branes and D6-branes**

Considering a bound state consisting on $p$ D0-branes and $q$ D6-branes, the tadpole is

$$(pk + qN) \int A, \quad (3.11)$$

and this term vanishes when $p = -\frac{N}{k}q$. The leading term in the WZ piece is zero, as we just saw, so the mass of this system is

$$M_{D0-D6} = \sqrt{p^2M_{D0}^2 + q^2M_{D6}^2}. \quad (3.12)$$

In the case of $p \sim q$ and $N \gg k$ needed for the validity of the supergravity approximation, we can write

$$M_{D0-D6} \simeq qM_{D6} \sim qL_{\text{string}}^6 g_s \propto qN \left( \frac{N}{k} \right)^{1/6}. \quad (3.13)$$

But in general, the formula is symmetric under the interchange of $M_{D0}$ with $M_{D6}$ and $p$ with $q$.

**D2-branes and D4-branes**

In addition, we see that D2-branes and D4-branes are tadpole free, since if we consider that D2-branes on $\mathbb{CP}^1 \subset \mathbb{CP}^2$ and D4-branes on $\mathbb{CP}^2$, the $\alpha$-dependent Wess-Zumino terms

$$\int_{\mathbb{CP}^1 \times \mathbb{R}_t} dC_1 \wedge A \quad \text{and} \quad \int_{\mathbb{CP}^2 \times \mathbb{R}_t} dC_3 \wedge A \quad (3.14)$$

will be zero at the minimum. Indeed,

$$\int_{\mathbb{CP}^1} dC_1 = a_0(\alpha) \int_{\mathbb{CP}^1} 2\mathcal{J} = -2\pi a_0(\alpha) \propto \sin^2 \alpha$$

$$\int_{\mathbb{CP}^2} dC_3 = 3\sqrt{3}L^3 e^{-\phi_0/4} \frac{7 + 3\cos 2\alpha}{(3 + \cos 2\alpha)^2} \sin^4 \alpha \int_{\mathbb{CP}^2} \mathcal{J} \wedge \mathcal{J} \propto \sin^4 \alpha, \quad (3.15)$$
so are both minimized by \( \alpha = 0 \), where they take the value zero. In the absence of magnetic flux, these are the only tadpoles that could appear.

The leading term in the WZ piece for the D2-brane, coming from \( \int C_3 \), is trivially zero, but can be made nonzero by considering a moving trajectory, \( \eta = \eta(t) \) (so that the rest is \( \int_{\mathbb{C}P^1} J = -\pi \)). The leading term in the WZ piece for the D4-brane, coming from \( \int C_5 \), is also trivially zero, but can be made nonzero by a moving trajectory, again \( \eta = \eta(t) \) (or rather, \( \psi = \psi(t) \)). We will analyze these later.

**Branes with worldvolume magnetic flux**

Instead, we can consider a worldvolume magnetic flux given by \( F = N J \) in \( S^2 \equiv \mathbb{C}P^1 \in \mathbb{C}P^2 \), where \( J \) is the Kähler form of \( \mathbb{C}P^2 \), at fixed \( \lambda \), and \( N \in 2\mathbb{Z} \), see [27–29]. For now, we ignore the subtle issue of the Freed-Witten anomaly [30,31].

The D2-brane wrapping \( \mathbb{C}P^1 \), for any \( \alpha \) (including \( \alpha = 0 \)), develops the coupling (from the \( \int F_0 \wedge F \wedge A_{WZ} \) term)

\[
-kN^2 T \int_{\mathbb{R}} dt A_t ,
\]

where we have used the fact that \( \int J = -\pi \) in \( \mathbb{C}P^1 \), so that now \( kN/2 \) fundamental strings are required to cancel this tadpole.

The magnetic flux also induces a dissolved D0-brane charge of \( N \) from the usual WZ coupling

\[
T_{D2} \int_{\mathbb{C}P^1} F \wedge \int_{\mathbb{R}_t} C_1 = -NT \int_{\mathbb{R}_t} C_1 .
\]

Moreover, the DBI term in the mass of the D2-brane wrapping the squashed space \( \tilde{\mathbb{C}P}^1 \) is

\[
M_{D2}(\alpha) = \frac{T_{D2}}{g_s^2} \int_{\tilde{\mathbb{C}P}^1} \sqrt{\det(G_{\alpha\beta} + 2\pi\alpha' F_{\alpha\beta})}
= \frac{\pi T_{D2}}{2g_s^2} \int_0^\pi d\theta \sqrt{\left[ (\Xi^2 - \Xi\Omega)L_{\text{string}}^4 + (\pi\alpha'N)^2 \right] \sin^2 \theta + L_{\text{string}}^4 \Xi\Omega} ,
\]

which is an elliptic integral. For the sake of simplicity, we ignore \( \Omega \), then

\[
M_{D2}(\alpha) = \frac{T_{D2}}{g_s^2} \int_{\mathbb{C}P^1} \sqrt{\det(G_{\alpha\beta} + 2\pi\alpha' F_{\alpha\beta})}
= \frac{\pi T_{D2}}{g_s^2} \left( \Xi^2 L_{\text{string}}^4 + (\pi\alpha'N)^2 \right)^{1/2} ,
\]

and we see that the mass of the brane has the usual term related to the brane wrapping an internal cycle, and a shift related to the magnetic charge \( N \). The first (flux-independent) term is proportional to

\[
\sin^4 \alpha(5 + \cos 2\alpha)^{1/4} ,
\]
so at $N = 0$, the whole mass (WZ term plus DBI) is minimized by $\alpha = 0$, at value $M = 0$. The second term however, is proportional to
\[
\frac{3 + \cos 2\alpha}{(5 + \cos 2\alpha)^{3/4}},
\]
which is minimal at $\alpha = \pi/2$ and maximal at $\alpha = 0$. Together, at $N \neq 0$, the mass of the D2-brane (DBI plus vanishing WZ term) is minimized at $\alpha \neq 0$, for a nonzero mass.

The **D4-brane** wrapping the $\mathbb{CP}^2$ cycle at nonzero magnetic flux has a tadpole coming from
\[
-k\frac{N^2}{8} T \int_{R_t} dt A_t,
\]
and we need $kN^2/8$ fundamental strings to cancel this tadpole. Observe that now we cannot guarantee that $kN^2/8$ is an integer, since $N^2 \in 4\mathbb{Z}$. Similar to what occurs in the analysis [28], this suggests that a fractional number of fundamental strings should be added to the D4-brane worldvolume to cancel this tadpole. Moreover, we have a shift in the value of the D4-brane mass due to the magnetic field $F = N\mathcal{J}$, giving
\[
M_{D4}(\alpha) = \frac{\pi^2 T_{D4}}{2g_s^\alpha} \left( \Xi^2 L_{\text{string}}^4 + (\pi\alpha'N)^2 \right),
\]
where we have deliberately ignored the squashed term $\Omega$ in the metric $^4$. Exactly the same comments as for the D2-brane case apply for the minimization with respect to $\alpha$.

The D4-brane on $\mathbb{CP}^2$ also has an induced dissolved D2-brane charge coming from the WZ term
\[
S = 2\pi T_{D4} \int_{R_t \times \mathbb{CP}^2} C_3 \wedge F = \frac{N}{2} T_{D2} \int_{R_t} C_3
\]
and a dissolved D0-brane charge coming from the WZ term
\[
S = \frac{1}{2} (2\pi)^2 T_{D4} \int_{R_t \times \mathbb{CP}^2} = \frac{N^2}{8} D_{D0} \int_{R_t} C_1.
\]

Finally, the **D6-brane** does not have any tadpole related to the Romans mass $F_0$, since $\mathcal{J} \wedge \mathcal{J} \wedge \mathcal{J} = 0$. The reader should compare this result with [28], where the

---

$^4$In fact, the complete expression has the square root of the following determinant

\[
\det(G + 2\pi\alpha'F) = \frac{1}{128} \sin^2 \theta \sin^6 \lambda \left( L_{\text{string}}^4 \Xi^2 + \pi^2 \alpha'^2 N^2 \right) \times
\]
\[
\times \left[ \cos 2\lambda \left( L_{\text{string}}^4 \Xi (\Xi - \Omega) + \pi^2 \alpha'^2 N^2 \right) + L_{\text{string}}^4 \Xi (\Xi + \Omega) + \pi^2 \alpha'^2 N^2 \right].
\]
Romans mass contributes to the tadpole in a deformation of the ABJM theory [32]. On the other hand, the DBI contribution to the mass of the D6-brane is given by

\[ M_{D6} = T_{D6} \int d^6 \xi e^{-\phi} L_{\text{string}}^2 \sqrt{\text{det}(G_{SS5})} \left( L_{\text{string}}^4 \Xi^2 + (\pi \alpha')^2 \right), \]  

(3.25a)

where \( \text{det}(G_{SS5}) \) is the determinant (2.1d), so

\[ M_{D6} = \frac{\sqrt{3}}{8\sqrt{2}} T_{D6} \int d^6 \xi e^{-\phi} \sqrt{\Omega} L_{\text{string}}^2 \cos \lambda \sin^3 \lambda \sin \theta \left( L_{\text{string}}^4 \Xi^2 + (\pi \alpha')^2 \right) \]
\[ = \frac{3}{2} \sqrt{\frac{3}{2}} T_{D6} \int_0^\pi d\alpha \sqrt{\Omega} L_{\text{string}}^2 g_8 \left( L_{\text{string}}^4 \Xi^2 + (\pi \alpha')^2 \right), \]

(3.25b)

and we see that the magnetic flux shifts the mass of the D6-brane wrapping the internal manifold. Moreover, now we have an integration over \( \alpha \), so we don’t need to minimize with respect to it. The contribution of the WZ term \( \int C_7 \), where \( \tilde{F}_8 = -e^{\phi/2} \tilde{F}_2 \), is zero, since \( C_7 \) doesn’t have a term that covers the whole compact space (and time). Therefore the mass is given entirely by the DBI term.

In this case again there are induced dissolved D-brane charges, D2-brane charge coming from

\[ \frac{1}{2} T_{D6} \int C_3 \wedge F \wedge F, \]

(3.26)

but no D0-brane charges, since

\[ T_{D6} \int C_1 \wedge F \wedge F = 0 \]

(3.27)

gives zero \( (\mathcal{J} \wedge \mathcal{J} \wedge \mathcal{J} = 0) \).

### 3.2 Field theory dual: baryon operators

We would like to understand what these particle-like branes with strings ending on them mean from the point of view of the dual field theory.

We start by summarizing the results for the various branes we have found, in table (1).

The static solitonic branes with strings attached to them correspond to baryon vertex operators (when introducing external quarks in the theory), as understood first by Witten [33] in the context of the D5-brane wrapping \( S^5 \) in \( AdS_5 \times S^5 \) for \( \mathcal{N} = 4 \) SYM. More precisely, in that case for the gauge group \( SU(N) \), one could construct the baryon

\[ B^{I_1...I_N} = \epsilon_{i_1...i_N} q^{j_1I_1}...q^{j_NI_N}, \]

(3.28)
Dp-branes | Mass $M_{Dp}$ | $q = \#$ Strings
--- | --- | ---
D0-branes | $T_{D0}/g_s^2$ | $k$
D2-branes | $\pi T_{D2} \left( \Omega^2 L_{\text{string}}^4 + (\pi \alpha' N)^2 \right)^{1/2}/g_s^{\alpha}$ | $kN^2/2$
D4-branes | $\pi^2 T_{D4} \left( \Omega^2 L_{\text{string}}^4 + (\pi \alpha' N)^2 \right)/2g_s^{\alpha}$ | $kN^2/8$
D6-branes | $\sqrt{3/2\pi^3} T_{D6}/g_s \int d\alpha \frac{\sqrt{\Omega L_{\text{string}}^4 \alpha}}{\gamma(\alpha)} \left( L_{\text{string}}^4 \Omega^2 + (\pi \alpha' N)^2 \right)$ | $N$

Table 1: Branes configurations.

and the external (heavy) quarks $q^{i_1 k_k}$ correspond to long strings coming from the boundary and reaching the brane. The mass of the brane (3.10) corresponds to the mass of the baryon with the quark masses subtracted, i.e. the baryon vertex operator.

The field theory dual to the GJV solution is also a $SU(N)$ SYM theory, though now with a CS term at level $k$. As such, we again expect the presence of the same baryon vertex constructed using the $\epsilon_{i_1...i_N}$ tensor. We indeed find this from the D6-brane wrapped over the compact space, which indeed corresponds in the T-dual type IIB theory to the D5-brane wrapped over the compact space.

The D2-brane and D4-brane baryons are harder to understand, but they appear only in the presence of magnetic flux, so they represent some interesting dynamical objects, that should be studied further.

Also the D0-branes, giving a baryon made up of $k$ external quarks, are harder to understand from the point of view of the $SU(N)$ gauge theory. But it is known that many Chern-Simons gauge theories have level-rank duality, as reviewed, derived and extended in the recent paper [34]. In certain cases, an $SU(N)_k$ theory is dual to an $SU(k)_N$ theory [35, 36], or even in the case of $U(N)_k$ we can have a duality to $U(k)_N$ [37]. In [34], a duality valid in general was proposed between a $SU(N)$ theory at level $k$ and an $U(k)$ theory at level $-N$.

In our case, the theory contains other fields besides the gauge fields, and also a SYM term, not just the CS term (the SYM term however is subdominant to the CS term at low energies), so the physics is not very clear, but we would expect from the level-rank dual formulation to have at the very least a baryon constructed with the $\epsilon_{i_1...i_k}$ tensor. Moreover, the mass of this baryon vertex must match (3.7). An interesting observation is that both (3.7) and (3.10) are proportional to $T_{D0}(N/k)^{1/6} = T_{D0}\lambda^{1/6}$, whereas the D0-brane mass is proportional to $k$ and the D6-brane mass with $N$. This suggests that level-rank duality certainly plays a role, in exchanging the $N$ and $k$ prefactors, whereas the coupling dependence stays the same $\lambda^{1/6}$, and is not inverted as naive replacing of $N$ with $k$ would suggest.
Finally, we have also bound states of the D0-branes and D6-branes, giving new bound states of the two types of baryon vertices. Again from the point of view of the field theory, we have evidence of level-rank duality, when we exchange \( N \) with \( k \), \( p \) with \( q \), while leaving \( \lambda = N/k \) invariant, as seen in (3.12). The case of \( p = -\frac{N}{k}q \) (the minus sign signifies considering anti-baryons) is very interesting: in this case there is no tadpole, so it would seem like we don’t need external quarks, but rather have a solitonic object composed of only glue, and yet with the symmetry properties of a combination of baryons. Unlike the case of a usual \( N \)-baryon/\( N \)-antibaryon combination, where the result would be annihilation, in this case the bound state would seem to be stable, which is quite unusual.

We see that we have strong evidence for level-rank duality in the field theory and, since such a relation is expected for our theory, this also is strong evidence for the correct identification of the field theory dual to the gravitational GJV solution.

Another observation is that it is expected that the external magnetic flux breaks the level-rank duality, and indeed we see that the D2 and D4 baryonic vertices are not level-rank dual to each other (or to themselves).

### 3.3 Brane stability and operator bounds

Now we try to proceed as in [27,28] and analyze the dynamical stability of the brane configurations of subsection (3.1). This will give bounds on the magnetic fluxes, that can be reinterpreted as bounds on the dissolved charges (since those depend only on \( N \), as we saw).

We want to consider the system of a D\(_p\)-brane wrapping the \( p \)-cycle and \( q \) fundamental strings necessary to cancel the tadpole, that is

\[
S = S_{Dp} + S_{qFS} ,
\]

where we consider the string at fixed \( \alpha \), defined by the minimum in the mass of the D\(_p\)-brane, \( \alpha_{min} \).

\[
S_{Dp} = -M_{Dp} \int dt \ L_{string} u \equiv -M_{Dp}^L \int dt \ u \quad (3.30a)
\]

\[
S_{qFS} = -qTL_{string}^{2} \alpha_{min.} \int dx dt \sqrt{u^4 + u'^2} \quad (3.30b)
\]

and we have considered a string configuration with \( x = -\sigma, t = \tau \) and \( u = u(\sigma) \). There are two contributions to the equations of motion of this system, one from the...
bulk and another from the boundary [38–40]. These equations are, respectively,

$$\partial_{\sigma} \frac{\partial \mathcal{L}}{\partial x^\prime} = 0 \Rightarrow \frac{u^4}{\sqrt{u^4 + u^2}} = c_0$$

(3.31a)

Boundary \Rightarrow \frac{u^0}{\sqrt{u_0^4u_0^2 + u_0^2}} = \frac{M_{Dp}^L}{L_{\text{string},\alpha,\text{min},qT}^2} \text{.} \quad (3.31b)

We define

$$\sqrt{1 - \beta^2} \equiv \frac{M_{Dp}^L}{L_{\text{string},\alpha,\text{min},qT}^2} \Rightarrow \beta = \sqrt{1 - \left( \frac{M_{Dp}^L}{L_{\text{string},\alpha,\text{min},qT}^2} \right)^2}, \quad (3.32)$$

so that we write the equations of motion for the Dp-brane q-strings as one single equation

$$\frac{u^4}{\sqrt{u^4 + u^2}} = \beta u_0^2 \text{.} \quad (3.33)$$

Integrating this equation, we find the size of the brane configuration,

$$l_{wb} = \frac{1}{u_0} \int_1^\infty dy \frac{\beta}{y^2 \sqrt{y^4 - \beta^2}}, \quad (3.34)$$

where \(y = u/u_0\). This equation is similar to the equations in [27,28], and the integral is solved in terms of hypergeometric functions.

**D0-brane**

Consider first the D0-brane. Reality of the function (3.32) implies

$$0 < \frac{M_{D0}^L}{L_{\text{string},\alpha,\text{min},qT}} = \frac{2\pi \ell_s}{g_{s,\text{min},kL_{\text{string},\alpha,\text{min}.}}} < 1 , \quad (3.35)$$

but this is always satisfied, because from (3.1) we have

$$1 > \frac{\ell_s}{g_s^\alpha L_{\text{string},\alpha}} > \frac{2\pi \ell_s}{g_s^\alpha L_{\text{string},\alpha} k} . \quad (3.36)$$

Consider next D2-branes and D4-branes with worldvolume magnetic flux.

**D2-brane**

Neglect the squashed term \(\Omega\) in the metric. For the D2-brane, with \(q = k\mathcal{N}/2\), reality of \(\beta\) in (3.32) implies

$$\frac{M_{D2}}{L_{\text{string},\alpha,\text{min},T}} < \frac{k\mathcal{N}}{2} \text{,} \quad (3.37)$$
which gives, since $\pi T_{D2}/T = 1/(4\pi \alpha')$,

$$
\left( \frac{\Xi L_{\text{string,a,min}}}{2 \ell_s g_{s,\text{min}}^a} \right)^2 + \left( \frac{kN}{2} \right)^2 \left( \frac{\sqrt{3}(3 + \cos 2\alpha_{\text{min.}})}{2(5 + \cos 2\alpha_{\text{min.}})} \right)^2 < \left( \frac{kN}{2} \right)^2,
$$

(3.38)

which is a lower bound on $q = kN/2$, or (at fixed $k$) on the dissolved charge $N$. Parametrically, we obtain

$$
(kN)^2 > O[N^{2/3}k^{1/3}] \Rightarrow N > O \left[ \left( \frac{N}{k} \right)^{1/3} \right].
$$

(3.39)

In [27,28], the authors showed that there are stable D2-brane configurations in the presence of magnetic flux $N$ until some upper bound, interpreted as an upper bound on dissolved charges, related to the stringy exclusion principle. In the case (3.38) however, we have a lower bound, which means that stability of this configurations implies the presence of a minimum magnetic flux on the brane worldvolume.

**D4-brane**

A similar situation occurs for the D4-brane, with $q = kN^2/8$. Stability of the configuration requires that $\beta$ in (3.32) is real, which implies

$$
\frac{M_{D4}}{L_{\text{string,a,min,T}}} < \frac{kN^2}{8}.
$$

(4.40)

This in turn gives

$$
\frac{1}{2} \left[ \frac{\Xi^2 L_{\text{string,a,min,}/\ell_s^3}}{8\pi g_s^a} + \frac{kN^2 \sqrt{3}(3 + \cos 2\alpha_{\text{min.}})}{8(5 + \cos 2\alpha_{\text{min.}})} \right] < \frac{kN^2}{8},
$$

(3.41)

which is again a lower bound on $q = kN^2/8$, or (at fixed $k$) on the dissolved D0-brane charge $N^2/8$. It is then also a lower bound on the magnetic flux on the worldvolume that makes the D4-brane stable, parametrically also

$$
kN^2 > O[N^{2/3}k^{1/3}] \Rightarrow N > O \left[ \left( \frac{N}{k} \right)^{1/3} \right].
$$

(3.42)

**D6-brane**

Finally, we consider the case of D6-branes, with $q = N$. In this case there is a small difference: the coordinate $\alpha$ is integrated over on the D6-brane worldvolume, but the strings need to be at given $\alpha$. Minimizing their action means that their $L_{\text{string}}^2$ factor must be minimum, i.e. for $\alpha = \pi/2$, when

$$
L_{\text{string}}(\pi/2) g_s = \frac{2\pi \ell_s}{k} \sqrt{\frac{2}{3}}.
$$

(3.43)
The stability bound is again the reality of $\beta$, which gives
\[
\frac{M_{D6}^2}{L_{\text{string}}^2(\pi/2)T} = \frac{M_{D6}}{L_{\text{string}}(\pi/2)T} < N ,
\]
and is rewritten as
\[
\frac{k}{(2\pi \ell_s)^6} \pi^3 \int d\alpha \sqrt{\Omega \alpha} L_{\text{string}}^2 [L^4 \Xi^2 + (\pi \ell_s N)^2] < N .
\]

This is now really an upper bound on the magnetic flux $N$, or more precisely on the induced dissolved D2-brane charge $\sim N^2$, just like in [27, 28]. In order of magnitude, we obtain
\[
k \left[ \mathcal{O} \left( \frac{N}{k} \right) + \mathcal{O}^2 \left( \left( \frac{N}{k} \right)^{1/3} \right) \right] < N \Rightarrow N^2 < \mathcal{O} \left( \left( \frac{N}{k} \right)^{2/3} \right) .
\]

In conclusion, we see that D0-branes are always stable, but the regions of stability of the D2-branes and D4-branes, and of the D6-branes are parametrically opposite: $N > \mathcal{O}[(N/k)^{1/3}]$ and $N < \mathcal{O}[(N/k)^{1/3}]$, respectively. There might be a window for all of them to be stable, depending on the exact numerical factors, which one would have to compute numerically.

### 3.4 Reducing the number of fundamental strings

Following [29, 38] we can consider a configuration with a reduced number $r$ of fundamental strings going to the boundary, the rest of the strings (up to the number required to cancel the tadpole) can go to the IR of the gravity solution. In holographic terms, this means that the baryons we consider have less quarks than the baryons of the previous subsections.

Using the conventions of [29], the configuration we consider consists of a D$p$-brane wrapped on a $p$-cycle and located at $u = u_0$ in the radial direction. In addition, we consider $l$ strings stretching from $u_0$ to the boundary of AdS4 (parametrized in polar coordinates) and $(q - l)$ straight strings stretching from $u_0$ to $u = 0$. The action is given by
\[
S = S_{DBI} + S_{lFS} + S_{(q-l)FS}
\]
where
\[
S_{DBI}^{Dp} = -M_{Dp} L_{DBI} \int dt u
\]
\[
S_{lF1} = -l T_{F1} L_{\text{string}}^2 \int dt du \sqrt{1 + u^4 r^2}
\]
\[
S_{(q-l)F1} = -(q - l) T_{F1} L_{\text{string}}^2 \int dt u .
\]
The equation of motion for the $l$ strings implies that
\[ r' = \frac{\tilde{u}^2}{u^2 \sqrt{u^4 - \tilde{u}^4}} , \]  
(3.49)
where $0 \leq \tilde{u} \leq u_0$ is the turning point of each string, and we see that at the turning point $r' \to \infty$. Moreover, as in [29], the boundary equation can be written as
\[ \frac{1}{a} \sqrt{1 - \tilde{\beta}^2} + \frac{1}{a} (1 - a) = \sqrt{1 - \frac{\tilde{u}^4}{u_0^4}} \leq 1 \]  
(3.50)
where $a = l/q$ and
\[ \sqrt{1 - \tilde{\beta}^2} = \frac{M_{Dp}^L}{L_{string}^2 T_{F1} q} \leq 1 , \]  
(3.51)
and this bound must be satisfied in order to get a stable configuration. Moreover, from the boundary equation (3.50) we conclude that
\[ l \geq \frac{q}{2} \left( \sqrt{1 - \tilde{\beta}^2} + 1 \right) \]  
(3.52)
and this bound defines the minimum value of quarks to create a stable baryon in the field theory. Furthermore, from the table 1 we see that fundamental strings attached to D2-branes and D4-branes are possible just in the presence of magnetic field, therefore, the condition (3.52) also depends on the magnitude of the magnetic field on the brane worldvolume. We can easily see that for $\beta = 0$, that occurs when $M_{Dp}^L = L_{string}^2 T_{F1} q$, the quark configurations are made of $q$-quarks, and the results reduce to what we obtained in the previous subsection.

Moreover, using (3.49) we can easily show that the size of this configuration is
\[ l_{wb} = \frac{\tilde{u}^2}{u_0^2} \int_1^\infty dz \frac{1}{z^2 \sqrt{z^4 - \frac{\tilde{u}^4}{u_0^4}}} , \]  
(3.53)
where $z = u/u_0$, and similarly to (3.34), this result can be integrated in terms of hypergeometric functions, giving as there
\[ l_{wb} = \frac{\tilde{u}^2}{u_0^2} F_1 \left( \frac{1}{2}, \frac{3}{4}, \frac{7}{4}; \frac{\tilde{u}^4}{u_0^4} \right) . \]  
(3.54)

3.5 Giant gravitons: gravity calculation

Giant gravitons in a gravitational solution correspond to solitonic states, obtained by wrapping D-branes on cycles in the geometry, which are therefore extended states,
that are moving in a direction transverse to the cycle, and that are degenerate in energies with graviton states. A proper treatment of the giant gravitons will take a separate paper, so here we will just sketch the main points.

The GJV gravity solution with metric (2.1a) is a solution of massive type IIA string theory, and we saw that there are wrapped D2-branes and D4-branes that are tadpole-free (in the absence of magnetic flux), thus could be interpreted as as giant gravitons. Moreover, we have already said that we could obtain a nonzero mass (by a nonzero WZ term) for a moving brane, whereas the static brane will have vanishing mass. This is exactly the giant graviton case.

1. We can obtain a standard kind of giant graviton by wrapping a D2-brane on an $S^2$. The $AdS_4$ metric to be considered is

$$ds^2_{AdS_4} = -(1 + r^2)dt^2 + \frac{dr^2}{1 + r^2} + r^2 d\Omega^2_2,$$

where $d\Omega^2_2 = d\vartheta^2 + \sin^2 \vartheta d\varphi^2$ parametrizes the two sphere $S^2$, on which the D2-brane is wrapped.

2. Another type of giant graviton is obtained by wrapping a D2-brane on an $\mathbb{CP}^1 = S^2$ inside the compact geometry. We can consider the $S^2 = \mathbb{CP}^1 \subset \mathbb{CP}^2$ defined by $J$. By considering the leading WZ term $\int C_3$ in the case when $\eta = \eta(t)$, we will obtain a nonzero contribution to the mass, proportional to

$$\frac{7 + 3 \cos 2\alpha}{(3 + \cos 2\alpha)^2} \sin^4 \alpha \dot{\eta},$$

but the DBI term for the moving brane will also be modified.

3. Yet another type of giant graviton will be obtained by considering D4-branes wrapping the $\mathbb{CP}^2$. Again, the leading WZ term in $\int C5$ for $\eta = \eta(t)$ will give a nonzero contribution to the mass (note that $\tilde{F}_6 = -e^{\phi/2} \ast \tilde{F}_4$).

### 3.5.1 D2-brane on $S^2 \subset AdS_4$

We consider the metric (3.55) for the $AdS_4$ space, with the sphere $S^2$ parametrized by $(\vartheta, \varphi)$. The ansatz for the giant gravitons is given by

$$\xi^0 = t, \xi^1 = \vartheta, \xi^2 = \varphi, \psi = \psi(t),$$

and we set $\lambda = \pi/2$ and $\alpha = \pi/2$. We study the giant gravitons dynamics following the well known recipe [41–43], in particular, giant gravitons in the GJV solution are similar to the configurations considered in the ABJM case [44–46]. The induced metric on the brane is

$$ds^2_{D2} = L_{string}^2 \left[ \left( \frac{9}{4} \dot{\psi}^2 - (1 + r^2) \right) dt^2 + r^2 d\Omega^2_2 \right].$$
and the DBI plus WZ action is

\[ S_{D2} = -4\pi T_{D2} \frac{L_{\text{string}}^3}{g_s} \int dt \left( r^2 \sqrt{1 + r^2 - \chi^2} - r^3 \right) \]  

(3.59)

where we have defined \( \chi \equiv \frac{3}{2} \psi \). When we write the momentum \( P_\chi \) as

\[ P_\chi = 4\pi T_{D2} \frac{L_{\text{string}}^3}{g_s^\alpha} \frac{r^2 \dot{\chi}}{\sqrt{1 + r^2 - \chi^2}} \equiv 4\pi T_{D2} \frac{L_{\text{string}}^3}{g_s^\alpha} p \]  

(3.60)

and the Hamiltonian is simply

\[ \mathcal{H} = \frac{4\pi T_{D2} L_{\text{string}}^3}{g_s^\alpha} \left( \sqrt{(1 + r^2)(p^2 + r^4)} - r^3 \right) \]  

(3.61)

and this functional has two minima, with \( \mathcal{H} = P_\chi \), namely \( r = 0, p \) and the latter we call giant graviton. Furthermore, if we insert the giant graviton into (3.60) we find \( \chi = t \), so that the angular velocity \( \dot{\chi} \) equals the speed of light.

As a technical detail, one may notice that the giant gravitons in [44, 45] move in a circle \( S^1 \subset \mathbb{C}P^3 \) parametrized by the coordinate \( \sigma \) in the Fubini-Study metric

\[ ds_{\mathbb{C}P^3} = d\lambda^2 + \frac{1}{4} \sin^2 \lambda (d\bar{\theta}^2 + \sin^2 \theta d\phi^2) + \frac{1}{4} \cos^2 \lambda (d\tilde{\theta}^2 + \sin^2 \tilde{\theta} d\tilde{\phi}^2) \]

\[ + \frac{1}{4} \cos^2 \lambda \sin^2 \lambda (d\sigma + \cos \theta d\phi - \cos \tilde{\theta} d\tilde{\phi}) , \]  

(3.62)

that has a subspace \( \mathbb{C}P^2 \) for constant \( (\tilde{\theta}, \tilde{\phi}) \). Therefore, in order to have a proper identification of the giant graviton of this section with the giants of [44, 45], we must consider the motion confined in the coordinate \( \sigma \), instead of \( \psi \), in squashed 6-sphere of the GJV solution. The derivation is isomorphic to what we have done so far, so we will not repeat the calculations.

### 3.5.2 D2-brane on the squashed \( S^2 \subset S S^5 \)

When we consider that the D2-branes wraps a two sphere inside the internal space \( S S^5 \) defined by (2.1c), the calculations are more involved because of the non-diagonal terms in the metric, but the idea is essentially the same, with one remarkable difference, the role of the angular coordinates, as we will see below.

The ansatz is given by

\[ \xi^0 = t , \xi^1 = \theta , \xi^2 = \phi , \psi = \psi(t) , \]  

(3.63)
and we set \( r = 0 \) and constant \( \lambda \) and \( \sigma \). The induced metric on the brane is

\[
ds_{D_2}^2 = L_{\text{string}}^2 \left[ (\Omega \dot{\psi}^2 - 1)dt^2 + \frac{\Xi \sin^2 \lambda}{4} d\theta^2 + 2\Omega \frac{\dot{\psi} \sin^2 \lambda \cos \theta}{2} dt d\phi \right. \\
\left. + \frac{\sin^2 \lambda}{4} \left[ \Xi (\sin^2 \theta + \cos^2 \lambda \cos^2 \theta) + \Omega \sin^2 \lambda \cos^2 \theta \right] d\phi^2 \right],
\]

(3.64)

and the Dirac-Born-Infeld action reads

\[
S_{\text{DBI}} = -\frac{T_{D_2} L_{\text{string}}^3 \pi}{2 g_s^2} \int d\theta dt \sin^2 \lambda \sqrt{\Xi (\Xi \cos^2 \theta \cos^2 \lambda + \Xi \sin^2 \theta + \Omega \cos^2 \theta \sin^2 \lambda)} \times \\
\times \sqrt{1 - \frac{(\Xi \cos^2 \theta \cos^2 \lambda + \Xi \sin^2 \theta - 3\Omega \cos^2 \theta \sin^2 \lambda)}{(\Xi \cos^2 \theta \cos^2 \lambda + \Xi \sin^2 \theta + \Omega \cos^2 \theta \sin^2 \lambda)} \Omega \dot{\psi}^2}.
\]

(3.65)

The \( \theta \)-integration can be carried out easily and gives an expression in terms of elliptic functions. But in order to avoid unnecessary complications, we will keep it as it is. Together with the Wess-Zumino term

\[
S_{WZ} = -\frac{T_{D_2} L_{\text{string}}^3 \pi}{2 g_s^2} \int d\theta \sin \theta \int dt \sin^2 \lambda \frac{3\sqrt{3}(7 + 3 \cos 2\alpha)}{(3 + \cos 2\alpha)^3} \sin^4 \alpha \dot{\psi},
\]

(3.66)

we have the D2-brane action

\[
S_{D_2} = - \int d\theta \int dt \left( f(\alpha, \lambda; \theta) \sqrt{1 - g(\alpha, \lambda; \theta) \dot{\psi}^2} - h(\alpha, \lambda; \theta) \dot{\psi} \right)
\]

(3.67)

where we write the action in terms of the functions \( f(\alpha, \lambda; \theta) \), \( g(\alpha, \lambda; \theta) \) and \( h(\alpha; \theta) \) given by

\[
f(\alpha, \lambda; \theta) = \frac{T_{D_2} L_{\text{string}}^3 \pi}{2 g_s^2} \sin^2 \lambda \sqrt{\Xi (\Xi \cos^2 \theta \cos^2 \lambda + \Xi \sin^2 \theta + \Omega \cos^2 \theta \sin^2 \lambda)}
\equiv f_0(\alpha) \sin^2 \lambda \sqrt{f_1(\alpha; \theta) \cos^2 \lambda + f_2(\alpha; \theta)}
\]

(3.68)

\[
g(\alpha, \lambda; \theta) = \frac{\Omega (\Xi \cos^2 \theta \cos^2 \lambda + \Xi \sin^2 \theta - 3\Omega \cos^2 \theta \sin^2 \lambda)}{(\Xi \cos^2 \theta \cos^2 \lambda + \Xi \sin^2 \theta + \Omega \cos^2 \theta \sin^2 \lambda)}
\equiv g_1(\alpha; \theta) \cos^2 \lambda + g_2(\alpha; \theta)
\]

(3.69)

\[
h(\alpha, \lambda; \theta) = -\frac{T_{D_2} \pi L_{\text{string}}^3 \sin \theta \sqrt{3}(7 + 3 \cos 2\alpha)}{2 g_s^2} \sin^4 \alpha \sin^2 \lambda \equiv h_1(\alpha; \theta) \sin^2 \lambda.
\]

(3.70)

For the sake of simplicity, we assume that \( \lambda = \pi/2 \).

With these definitions, the momentum (up to a \( \theta \)-integration) is

\[
P_\psi = \frac{g f \dot{\psi}}{\sqrt{1 - g \dot{\psi}^2}} + h,
\]

(3.71)
which we can invert to write \( \dot{\psi} \) in terms of \( P_\psi \), as

\[
\dot{\psi} = \frac{P_\psi - h}{\sqrt{(fg)^2 + g[P_\psi - h]^2}}. 
\]  

(3.72)

The Hamiltonian becomes

\[
\mathcal{H} = P_\psi \dot{\psi} - \mathcal{L} \\
= \frac{1}{g} \sqrt{g(P_\psi - h)^2 + f^2 g^2}.
\]  

(3.73)

Writing down explicitly the equation \( \partial_\alpha \mathcal{H} \equiv \mathcal{H}' = 0 \), we have

\[
-2g'\mathcal{H}^2 + \frac{1}{g} \left[ g'(2f^2 g + (P_\psi - h)^2) - 2g(P_\psi - h)h' + 2g^2 ff' \right] = 0,
\]

(3.74)

and solving the condition for the angle \( \alpha \) that follow from this equation, we find the pointlike and giant gravitons solutions.

The solution that corresponds to the pointlike graviton is given by sin \( \alpha \) cos \( \alpha \) = 0. Since \( \alpha = 0, \pi \) are isolated conical singularities, the system is not well defined at these points. We set \( \alpha = \pi/2 \) for the pointlike gravitons. For the giant graviton solution, we must solve the equation \( \partial_\alpha \mathcal{H} = 0 \), for \( \alpha \neq \pi/2 \), that gives an algebraic equation which must be solved for \( X = \sin^2 \alpha \).

The non-diagonal terms in the metric make the explicit verification of these algebraic conditions very involved. For simplicity then, we consider a dielectric brane, such that the electric field is conveniently chosen to cancel the non-diagonal terms of the metric \([47]\). In this somewhat contrived case, the D2-brane action (3.67) reduces to

\[
S_{D2} = -\int d\theta \int dt \left( f(\alpha, \lambda; \theta) \sqrt{1 - \Omega \dot{\psi}^2} - h(\alpha, \lambda; \theta) \psi \right),
\]

(3.75)

with momentum

\[
P_\psi = \frac{f \Omega \dot{\psi}}{\sqrt{1 - \Omega \dot{\psi}^2}} + h \Rightarrow \dot{\psi} = \frac{P_\psi - h}{\sqrt{(f \Omega)^2 + \Omega(P_\psi - h)^2}},
\]

(3.76)

and energy given by

\[
\mathcal{H} = \frac{1}{\Omega} \sqrt{(f \Omega)^2 + \Omega(P_\psi - h)^2},
\]

(3.77)

that is equivalent to the replacement \( g \rightarrow \Omega \) in the Hamiltonian (3.73). In this case the pointlike gravitons have again \( \alpha = \pi/2 \).
3.5.3 D4-brane on the squashed $\mathbb{CP}^2 \subset S^5$

Finally, we consider a D4-brane wrapping the whole squashed complex projective space $\mathbb{CP}^2$, so the induced metric on the D4-brane is

$$\begin{align*}
\left. ds^2_{D4} \right|_{S^5} = L^2_{\text{string}} \left\{ (-1 + \Omega \dot{\psi}^2) dt^2 + 2 \frac{\Omega \dot{\psi} \sin^2 \lambda}{2} (d\sigma + \cos \theta d\phi) dt + \Xi \frac{\sin^2 \lambda}{4} d\theta^2 + \Xi d\lambda^2 \\
+ \frac{\sin^2 \lambda}{4} [\Xi \sin^2 \theta d\phi^2 + (\Xi \cos^2 \lambda + \Omega \sin^2 \lambda) (d\sigma + \cos \theta d\phi)^2] \right\}.
\end{align*}$$

\hspace{1cm} (3.78)

It gives the Dirac-Born-Infeld action

$$S_{\text{DBI}} = -\tilde{f}(\alpha) \int dt d\lambda \sin^3 \lambda \sqrt{\Omega (1 - \cos 2\lambda) + \Xi (1 - \Omega \dot{\psi}^2)(1 + \cos 2\lambda)},$$

\hspace{1cm} (3.79)

where

$$\tilde{f}(\alpha) = T_{D4} \frac{\sqrt{2} L^5_{\text{string}} \pi^2/2}{g_s^2}. \hspace{1cm} (3.80)$$

Given the 6-form RR field $\tilde{F}_6$ defined by $\tilde{F}_6 = -e^{\phi/2} * \tilde{F}_4$, its restriction to $S^5$ is

$$\left. \tilde{F}_6 \right|_{S^5} = -\left( \frac{3 L^3 e^{-\phi_0/4}}{4} \sqrt{\frac{3}{2}} \Delta \sqrt{\Omega \Xi^2 e^{\phi/2} \sin^3 \lambda \cos \lambda \sin \theta} \right) \psi d\theta d\lambda d\phi d\sigma \hspace{1cm} (3.81)$$

where the wedge product of forms is implicit. We may write this expression as

$$\left. \tilde{F}_6 \right|_{S^5} = dC_5^{S^5}, \hspace{1cm} (3.82)$$

where

$$C_5^{S^5} = -\left( 81 L^5 e^{\phi_0/4} \sqrt{\frac{3}{2}} A(\alpha) \sin^3 \lambda \cos \lambda \sin \theta \right) \psi d\theta d\lambda d\phi d\sigma \hspace{1cm} (3.83)$$

and

$$A(\alpha) = \frac{\sin^5 \alpha}{(3 + \cos 2\alpha)^2} = \frac{1}{2} \arctan(\cos \alpha) - \frac{\cos \alpha}{4} - \frac{\cos \alpha}{3 + \cos 2\alpha}. \hspace{1cm} (3.84)$$

Therefore, the Wess-Zumino term for a D4-brane wrapping the squashed space $\mathbb{CP}^2$ is

$$S_{WZ} = -T_{D4} \int C_5^{S^5} = \bar{g}(\alpha) \int dt d\lambda \sin^3 \lambda \cos \lambda \dot{\psi}, \hspace{1cm} (3.85)$$

26
where we have defined \( \tilde{g}(\alpha) = 324T_{D4} \sqrt{6 \pi^2} e^{\phi_0/4} A(\alpha) \). Finally, the D4-brane action is simply

\[
S_{D4} = - \int dt d\lambda \left( \tilde{f}(\alpha) \sin^3 \lambda \sqrt{\Omega(1 - \cos 2\lambda) + \Xi(1 - \Omega \dot{\psi}^2)}(1 + \cos 2\lambda) - \tilde{g}(\alpha) \sin^3 \lambda \cos \lambda \dot{\psi} \right).
\]

(3.86)

We leave the \( \lambda \)-integral untouched, since the result is quite complicated. Therefore, the Hamiltonian (up to a \( \lambda \)-integration) is

\[
\mathcal{H} = \sqrt{\Xi(1 + \cos 2\lambda) + \Omega(1 - \cos 2\lambda)} \times
\]

\[
\sqrt{\tilde{f}^2 \sin^2 \lambda \Xi^2 \Omega^2 (1 + \cos 2\lambda)^2 + \Xi \Omega (P_{\psi} - \tilde{g} \sin^3 \lambda \cos \lambda)^2},
\]

(3.87)

and again, studying the condition that follows from \( \partial_\alpha \mathcal{H} = 0 \) we find the pointlike and giant graviton solutions.

### 3.6 Giant gravitons: field theory operators

As usual, the field theory operators corresponding to the giant gravitons are subdeterminants, of the type

\[
\epsilon_{a_1...a_k a_{k+1}...a_N} \epsilon^{b_1...b_k b_{k+1}...b_N} (Z_{b_1}^{a_1}...Z_{b_k}^{a_k}),
\]

(3.88)

or with \( W \) and \( T \) replacing any of the \( Z \) fields. More generally, the operators are Schur polynomials for some complicated represntation of the symmetry group.

- For the D2-brane wrapping \( S^2 \subset \mathbb{C}P^2 \), the fields inside the bracket are \( Z \)'s and \( W \)'s in an \( SU(2) \) invariant combination, forming representations of \( SU(2) \).

- For the D2-brane wrapping \( S^2 \subset AdS_4 \), we should replace the \( Z \)'s with \( D_a Z \)'s, where \( a \) corresponds to the two angles on \( \Omega_2 \), the spatial 2-sphere in \( AdS_4 \). Again, the combinations of \( D_a Z \)'s should be in some representation of \( SU(2) \).

- For the D4-brane wrapping \( \mathbb{C}P^2 \), we should have all the \( Z, W, T \) inside the bracket, transforming under \( SU(3) \) (the symmetry group of \( \mathbb{C}P^2 \)), i.e. forming a representation of this symmetry group.

### 3.7 Gauge coupling from wrapped brane

One can easily show that given a induced metric on a Dp-brane wrapping an \( n \)-cycle \( \Sigma^n \) of the form,

\[
d s^2_{Dp} = e^{2A} \eta_{\mu\nu} dx^\mu dx^\nu + d s^2_{\Sigma},
\]

(3.89)
the gauge coupling defined on the Minkowski worldvolume of the brane is
\[ \frac{1}{g_{YM}^2} = T_{Dp}(2\pi\alpha')^2 \int_{\Sigma} d^n\xi e^{(3+n-p)A-\phi} \sqrt{\det (G + B)_{ab}} \] (3.90)
where \( \phi \) is the dilaton and \( G_{ab} \) and \( B_{ab} \) are the metric and the Kalb-Ramond field along the \( n \)-cycle \( \Sigma^n \).

In the GJV solution, we can wrap a probe D4-brane on a 2-cycle parametrized by \((\theta, \phi)\) at \( \lambda = 0 \). In this case, the (3 dimensional) gauge coupling of the probe is given by
\[ \frac{1}{g_{YM}^2} = \Delta^{3/2} \Xi e^{-\phi/4} \frac{1}{y} \sim \frac{(N^2k)^{1/3}}{y} = \frac{N}{\lambda^{1/3}} \frac{1}{y}, \] (3.91)
where we have used the \( AdS_4 \) coordinate system \( ds^2_{AdS_4} = (dy^2 + \eta_{\mu\nu}dx^\mu dx^\nu) / y^2 \).

We observe that, as expected, the probe gauge coupling is now given by the curvature in string units as \( \propto \lambda^{1/6} \).

4 Strings in the geometry

4.1 Wilson loops

Despite the fact that the Yang-Mills gauge coupling is dimensionful in three dimensions, and that we are studying the gravity dual of a conformal field theory, Wilson loops are interesting observables to consider. Using the standard prescription of [39,40,48] in the metric background (2.1a), we consider a string configuration that consists of an open string with its endpoints attached to the \( AdS_4 \) boundary, \( u \to \infty \), at the points \( x = 0 \) and \( x = L_{qq} \), and that extends into the bulk and reaches a minimum radial coordinate \( u_0 \) exactly at \( x = L_{qq}/2 \).

The ansatz for this configuration is given by \( t = \tau, \ x = x(\sigma) \) and \( u = u(\sigma) \), so that the Nambu-Goto action is
\[ S = \frac{L_{string}^2}{2\pi\alpha'} \int dt d\sigma \sqrt{u'^4 + u'^2} \] (4.1)
where the prime denotes derivative with relation to \( \sigma \). From the equations of motion for this system we have
\[ \frac{du}{dx} = -\frac{u^2}{u_0^2} \sqrt{u^4 - u_0^4} \quad \text{for} \quad x < \frac{L_{qq}}{2} \] (4.2)
\[ \frac{du}{dx} = \frac{u^2}{u_0^2} \sqrt{u^4 - u_0^4} \quad \text{for} \quad x > \frac{L_{qq}}{2}. \] (4.3)
Using these equations, we can determined that the quark-antiquark distance is given by
\[
L_{q\bar{q}} = \frac{2}{u_0} \int_1^\infty \frac{1}{y^2 \sqrt{y^4 - 1}} = \frac{1}{u_0} \frac{(2\pi)^{3/2}}{\Gamma(1/4)^2}.
\] (4.4)
where \( y = u/u_0 \).

Furthermore, if we replace this solution, the quark-antiquark potential diverges, so that we renormalize this system by removing the mass of two W-bosons, that consists of two strings stretching from the boundary into the bulk of the AdS space. Therefore, we find that the potential is given by
\[
E_{q\bar{q}} = -\frac{(2\pi)^2}{\Gamma(1/4)^4} \frac{L_{\text{string}}^2}{\alpha' L_{q\bar{q}}},
\] (4.5)
which is similar to the result of [39]. It still has the conformal form \( \propto 1/L_{q\bar{q}} \), but there is an interesting difference when we write it in terms of the 't Hooft coupling \( \lambda \). In the \( AdS_5 \times S^5 \) case one obtains a quark-antiquark potential that behaves as the square root of the 't Hooft coupling, \( E_{q\bar{q}} \sim \sqrt{\lambda}/L_{q\bar{q}} \); but in our case, since the 't Hooft coupling is \( \lambda = N/k \) (see also [25, 32]), we have the one third power of the coupling,
\[
E_{q\bar{q}} \sim \frac{(2\pi)^{3/2}}{3^{5/3}(4 - \pi)^{1/3}\Gamma(1/4)^4} \frac{\sqrt{5 + \cos 2\alpha \lambda^{1/3}}}{L_{q\bar{q}}} \sim \frac{\lambda^{1/3}}{L_{q\bar{q}}}. \] (4.6)

4.2 Operators of large spin

Strings rotating around the circle \( S^2 \in AdS_4 \) in global coordinates will be dual to high spin operators [49], and the anomalous dimension of these operators in SYM is generically
\[
E - S = f(\lambda) \ln S.
\] (4.7)

We take the \( AdS_4 \) metric as
\[
d^{2}s_{AdS_4} = -\cosh^2 \rho dt + d\rho^2 + \sinh^2 \rho (d\vartheta^2 + \sin^2 \vartheta d\varphi^2) \] (4.8)
and we consider that the string is at the equator of \( S^2 \), \( \vartheta = \pi/2 \) and
\[
t = \tau, \quad \rho = \rho(\sigma), \quad \varphi = \omega \tau. \] (4.9)

The Nambu-Goto action is then
\[
S_{NG} = -\frac{4L_{\text{string}}^2}{2\pi \alpha'} \int_0^{\rho_0} d\rho \sqrt{\cosh^2 \rho - \sinh^2 \rho \dot{\varphi}^2}
\] (4.10)
and the 4 comes from the fact that the closed string forms a loop that consists of two parallel segments, and spins as a rigid rod around its center at $\rho = 0$ and extends to $\rho_0$, determined by $\omega^2 = \coth^2 \rho_0$ [49]. Similarly, the string energy and spin are

$$
E = \frac{4L_{\text{string}}^2}{2\pi \alpha'} \int_0^{\rho_0} d\rho \frac{cosh^2 \rho}{\sqrt{cosh^2 \rho - sinh^2 \rho \omega^2}}
$$

$$
S = \frac{4L_{\text{string}}^2}{2\pi \alpha'} \int_0^{\rho_0} d\rho \frac{\omega sinh^2 \rho}{\sqrt{cosh^2 \rho - sinh^2 \rho \omega^2}}
$$

respectively.

Consider now that the string length is much larger than the $AdS_4$ radius, $L \sim L_{\text{string}}$, then $S >> L_{\text{string}}^2$, and it corresponds to the limit $\omega \rightarrow 1$. Taking $\omega \approx 1 + 2\eta$ for $\eta << 1$, one can easily obtain $2\rho_0 = \ln(1/\eta)$ and

$$
E = \frac{L_{\text{string}}^2}{2\pi \alpha'} (1/\eta + \ln(1/\eta) + \cdots), \quad S = \frac{L_{\text{string}}^2}{2\pi \alpha'} (1/\eta - \ln(1/\eta) + \cdots),
$$

so that the cusp anomalous dimension is found to be

$$
f(\lambda) = \frac{L_{\text{string}}^2}{\pi \alpha'} \propto \lambda^{1/3},
$$

and the proportionality constants are easily obtained from (2.11). Note that, in contrast to [2, 49], the anomalous cusp dimensional scales as $\lambda^{1/3}$ instead of $\lambda^{1/2}$.

## 5 Entanglement entropy

The metric of the GJV solution (2.1a) has the form of a warped, squashed $AdS_4 \times S^6$. Because of this, it is worth to consider the calculation of the holographic entanglement entropy, according to the prescription of Ryu and Takayanagi [50], extended by Klebanov, Kutasov and Murugan to more general gravity duals in [51].

We consider a $d+2$ dimensional gravity dual, with a $d+1$ dimensional quantum field theory at its boundary, and we want to compute the entanglement resulting from introducing a closed $d-1$ dimensional spatial surface $\partial A$ that separates the spatial region $A$ from the rest of $d$ dimensional space (at constant time). Consider then the $d$ dimensional spatial surface $\gamma$ in the gravity dual that ends on the same boundary surface, $\partial \gamma = \partial A$. Then the holographic entanglement entropy is given by

$$
S_A = \frac{1}{4G_N^{(d+2)}} \int_\gamma d^d\sigma \sqrt{G_{\text{ind}}^{(d)}}.
$$

For a 10 dimensional metric, moreover in the presence of a nontrivial dilaton field $\phi$, we have instead

$$
S_A = \frac{1}{4G_N^{(10)}} \int_\gamma d^8\sigma e^{-2\phi} \sqrt{G_{\text{ind}}^{(8)}}.
$$
Here \( G_{\text{ind}} \) is the induced string frame metric on the surface \( \gamma \).

The string frame metric \( ds^2_{\text{string}} = e^{\phi/2}ds^2_E \) for the GJV solution, (2.1a), is

\[
ds^2_{\text{string}} = L^2 e^{\phi_0/2}(5 + \cos \alpha)^{1/2} \left[ ds^2_{\text{AdS}_4} + \frac{3}{2} d\alpha^2 + \Xi ds^2_{\mathbb{C}P^2} + \Omega \eta^2 \right],
\]

which can be put in the form

\[
ds^2_{\text{string}} = A(z) \left[ ds^2_{\text{AdS}_4} + dz^2 + g_{ij}(z) d\theta^i d\theta^j \right] + dz^2,
\]

where \( z = \alpha \sqrt{3/2} \) and \( A(z) = L^2 e^{\phi_0/2}(5 + \cos \alpha)^{1/2} \).

This type of metric is somewhat more general than metrics considered before, for instance than in [51].

Consider the region \( A \) to be the interval \((-l, l)\) in one of the spatial directions, called \( x \), times the full space in the others, so that \( \partial A \) are the two endpoints of the interval, times the full space in the other directions. The surface \( \gamma \) in the gravity dual is then a curve \( y(x) \) with boundary conditions \( y(-l) = 0 = y(l) \), where \( y \) is the radial coordinate of AdS. This is the same as in the simple \( AdS_{d+2}/CFT_{d+1} \) case. In our \( AdS_4 \) case, \( d = 2 \), and we can take \( x_1 = x \), \( x_2 \) being trivial, but the discussion is more general than this \( d = 2 \) case.

The induced metric on \( \gamma \) (with \( y = y(x) \)) is then in this more general case (with \( d - 1 \) coordinates \( \vec{x} \) and one \( x \))

\[
ds^2_{\text{string}} = A(z) \left[ dx^2(1 + y^2) + dx^2 \right] + dz^2.
\]

Denoting

\[
V_{\text{int}}(z) \equiv d^{D-d-3} \theta \int \sqrt{\det g_{ij}},
\]

the entanglement entropy of the interval becomes

\[
S_A \equiv \frac{1}{4G_N^{(10)}} \int d^{d-1}\vec{x} \int dz \int_{-l}^l dx e^{-2\phi} V_{\text{int}}(z) y(x)^{-d} A(z)^{d+1}.
\]

\[
= \left\{ \frac{1}{4G_N^{(10)}} \int dz e^{-2\phi(z)} V_{\text{int}}(z) A(z)^{d+1} \right\} \int d^{d-1}\vec{x} \int_{-l}^l dx y(x)^{-d} \sqrt{1 + (y'(x))^2}.
\]

The square brackets offer a constant renormalization of \( G_N^{(10)} \), but otherwise the result is the same as for \( AdS_{d+2} = AdS_4 \). The same profile for \( y(x) \) is obtained, and the same final result for the entanglement entropy as a function of \( l \).
We now turn to some large string theory objects, specifically giant magnons, that come from long (macroscopic) strings in the gravity dual, and correspond in the gauge theory to spin chain states of large momentum.

### 6.1 Gravity calculation

#### 6.1.1 Review of AdS$_5 \times S^5$ giant magnons

The giant magnons were defined by Hofman and Maldacena in [52]. Since the regular magnons (spin excitations) correspond to quantum states of the string on the pp wave, obtained as a Penrose limit of the gravity dual, giant magnons correspond to classical, i.e. long, strings in the gravity dual. Specifically, since we look for giant magnons in the $SU(2) = SO(3)$ sector of the field theory (made up from two complex scalars $Z$ and $W$), in the gravity dual the motion of the strings is restricted to $\mathbb{R}_t \times S^2$.

The spatial $S^2$ is embedded in the $S^5$ of AdS$_5 \times S^5$ as

$$ds^2_{S^5} = \sin^2 \theta d\phi^2 + d\theta^2 + \cos^2 \theta d\Omega^2_3,$$

by $d\Omega = 0$. We consider the gauge $t = \tau$, $\phi - t = \phi' \equiv \sigma$, where $(\tau, \sigma)$ are the string worldsheet coordinates. Then the induced metric on the string worldsheet is

$$ds^2_{\text{induced}} = -d\tau^2 - \frac{ds^2_{S^5}}{d\tau^2} d\tau^2 + \frac{ds^2_{S^5}}{d\sigma^2} d\sigma^2 + 2d\sigma d\tau \frac{ds^2_{S^5}}{d\tau} d\sigma.$$

Then the string action is

$$S = \frac{\sqrt{\lambda}}{2\pi} \int d\sigma \sqrt{-\text{det} g_{ab,\text{induced}}} d\tau = \frac{\sqrt{\lambda}}{2\pi} \int dt \int d\phi' \sqrt{\cos^2 \theta \phi'^2 + \sin^2 \theta},$$

and its (integrated) equation of motion is

$$\sin \theta = \frac{\sin \theta_0}{\cos \phi'},$$

and $\theta_0$ is an integration constant, such that $\phi' \in [-\pi/2 - \theta_0, +\pi/2 - \theta_0]$. This is a string that rotates around $S^2 \in S^5$, while describing an arc that starts and ends on the Equator, with an angle $\Delta \phi = \Delta \phi' = 2(\pi/2 - \theta_0)$ between the endpoints.

The (lightcone) energy of the string is

$$\epsilon = E - J = \frac{\sqrt{\lambda}}{\pi} \left| \sin \frac{p}{2} \right|.$$
6.1.2 Giant magnons in the gravity dual

In the GJV gravity dual, we could consider various giant magnon solutions (spinning classical strings). But here we are interested simply in embedding the simple $SU(2)$-invariant giant magnons from the $AdS_5 \times S^5$ case in the present context. For that, it suffices to find an $S^2$ fiber inside the metric (2.1a).

We can write the $\mathbb{CP}^2$ metric as (see (A.6))

$$ds^2_{\mathbb{CP}^2} = d\lambda^2 + \frac{1}{4} \sin^2 \lambda (\Sigma_1^2 + \Sigma_2^2 + \cos^2 \lambda \Sigma_3^2), \quad (6.6)$$

where the left-invariant one-forms are

$$\Sigma_1 = -\sin \sigma d\theta + \cos \sigma \sin \theta d\phi$$
$$\Sigma_2 = \cos \sigma d\theta + \sin \sigma \sin \theta d\phi$$
$$\Sigma_3 = d\sigma + \cos \theta d\phi. \quad (6.7)$$

Here $\lambda \in [0, \pi/2]$, $\sigma \in [0, 4\pi]$, $\theta \in [0, \pi]$ and $\phi \in [0, 2\pi]$. Note that

$$\Sigma_1^2 + \Sigma_2^2 = d\theta^2 + \sin^2 \theta d\phi^2, \quad (6.8)$$

so this combination forms an $S^2$.

We then have two obvious possibilities for $S^2$ embedding:

- $\lambda = \pi/2$, $\theta = \theta_0$, which gives (the range for $\theta$ and $\phi$ is also correct)

$$ds^2_{\mathbb{CP}^2} \to \frac{1}{4} (d\theta^2 + \sin^2 \theta d\phi^2) = \frac{1}{4} ds^2_{S^2}. \quad (6.9)$$

- $\sigma = \sigma_0$, $\phi = \phi_0$, which gives

$$ds^2_{\mathbb{CP}^2} \to (d\lambda^2 + \sin^2 \lambda (d(\theta/2))^2, \quad (6.10)$$

however with the range $\theta/2 \in [0, \pi/2]$, $\lambda \in [0, \pi/2]$. Since for the giant magnon solution we would need $\theta/2$ to be in $[0, 2\pi]$, we could extend the domain by symmetry (the metric is unchanged for the extension).

6.2 Field theory

As we saw, the dual field theory has 3 complex scalars in chiral multiplets, transforming under $SU(3)$, $Z, W, T$. For the giant magnons, we want to consider an $SU(2)$ ($=SO(3)$) sector, that corresponds to the motion on the $S^2$ with the same symmetry. We choose $Z, W$ to be the fields transforming under it.
We consider a spin chain formed from $Z$ and $W$ in the "dilute gas approximation", where the states are formed mostly from $Z$'s, with just a few $W$ excitations, similar to the BMN construction in 3+1 dimensions [53]. As there, the ground state is

$$|0, p^+\rangle = \frac{1}{\sqrt{JN}} T \{ [Z^J] \}.$$  

(6.11)

We consider a few excitations made by inserting in the $l$'th position $W e^{2\pi i l / J}$ inside the trace.

Exactly like in the case of 3+1 dimensional $\mathcal{N} = 4$ SYM, described in Appendix A of [46], we obtain a Hamiltonian with eigenenergies of

$$\epsilon(p) = \sqrt{1 + \frac{\lambda}{\pi^2} \sin^2 \frac{p}{2}},$$  

(6.12)

where $p = 2\pi n / J$ is the momentum of the giant magnon. For a regular magnon with $n \sim 1$, and in the limit $\lambda / J^2$ finite (as $\lambda, J \to \infty$) we would have

$$\epsilon(p) \sim \sqrt{1 + \frac{\lambda n^2}{J^2}},$$  

(6.13)

which is the result in the BMN limit, corresponding to the Penrose limit. But if we take instead the limit $\lambda$ fixed and large, $p \sim 1$, we get

$$\epsilon(p) = \frac{\sqrt{\lambda}}{\pi} |\sin \frac{p}{2}|,$$  

(6.14)

matching exactly the giant magnon solution in the gravity dual.

### 6.2.1 Hamiltonian and diagonalization

For completeness, we will reproduce some of the steps in Appendix A of [46], that give the energies above. The introduction of the various fields inside the trace (which gives a cyclic ordering) can be described by the introduction of Cuntz oscillators $a_i$, $i = 1, \ldots, J$ acting on a vacuum, i.e. something like $a_i^\dagger a_i b_i^\dagger a_i |0\rangle$, where $a$ and $b$ correspond to $Z$ and $W$, respectively. The Cuntz oscillators satisfy

$$a_i a_j^\dagger = \delta_{ij}; \quad \sum_i a_i^\dagger a_i = 1 - |0\rangle \langle 0|; \quad a_i |0\rangle = 0.$$  

(6.15)

If we only have a few "impurities" $W$ inside the trace, we can switch to a description in terms of independent Cuntz oscillators $b_i^\dagger$ at each site, satisfying

$$b_i b_i^\dagger = 1; \quad b_i^\dagger b_i = 1 - (|0\rangle \langle 0|); \quad b_i |0\rangle_i = 0,$$  

(6.16)
and
\[ [b_i, b_j] = [b_i^+, b_j] = [b_i^+, b_j^+] = 0, \quad \forall i \neq j. \] (6.17)

Defining the Fourier modes \( b_n \) by
\[ b_j = \frac{1}{\sqrt{J}} \sum_{n=1}^{J} e^{2\pi i j n} b_n, \] (6.18)
and acting only on states in the dilute gas approximation, i.e.
\[ |\psi_{\{n_i\}}\rangle = |0\rangle_{1,1}...|n_{i_1}\rangle_{j_1}...|n_{i_k}\rangle_{j_k}|0\rangle_J, \] (6.19)
one obtains the commutation relations
\[ [b_n, b_m^+]|\psi_{\{n_i\}}\rangle = \left( \delta_{nm} - \frac{1}{J} \sum_k e^{2\pi i j (m-n)} \right) |\psi_{\{n_i\}}\rangle; \quad [b_n, b_m] = [b_n^+, b_m^+] = 0, \] (6.20)
so, up to \( 1/J \) corrections, the usual oscillator commutation relations.

The interaction term in the Lagrangean (the same in 2+1 as in 3+1 dimensions)
\[ L_{\text{int}} = -\frac{g_Y^2}{2} \text{Tr} [Z, W][\bar{Z}, \bar{W}], \] (6.21)
where \( 4\pi g_s = g_Y^2 \), becomes equivalent, under the definition of the discretized field \( \phi_j = (b_j + b_j^+)/\sqrt{2} \), to
\[ -\frac{g_s N}{\pi} \sum_j (\phi_j - \phi_{j+1})^2. \] (6.22)

Then the total Hamiltonian acting on the states created by Cuntz oscillators, including a free part, is found to be
\[ H = \sum_{j=1}^{J} \frac{b_j b_j^+ + b_j^+ b_j}{2} + \frac{\lambda}{8\pi^2} \sum_{j=1}^{J} (b_{j+1} + b_{j+1}^+) (b_j + b_j^+ - (b_j + b_j^+)^2, \] (6.23)
where \( \lambda = g_Y^2 N \). This Hamiltonian can be diagonalized by the redefinition
\[ b_n = \frac{c_{n,1} + c_{n,2}}{\sqrt{2}}, \quad b_{J-n} = \frac{c_{n,1} - c_{n,2}}{\sqrt{2}}, \] (6.24)
followed by the Bogoliubov transformation
\[ \bar{c}_{n,1} = a_n c_{n,1} + b_n c_{n,1}^+, \quad \bar{c}_{n,2} = a_n c_{n,1} - b_n c_{n,1}^+, \quad a_n = \frac{(1 + \alpha_n)^{1/4} + (1 + \alpha_n)^{-1/4}}{2}, \quad b_n = \frac{(1 + \alpha_n)^{1/4} - (1 + \alpha_n)^{-1/4}}{2}. \]
\[ \alpha_n = \frac{\lambda}{8\pi^2} (\cos(2\pi n/J) - 1) = -\frac{\lambda}{(2\pi)^2} \sin^2 \frac{\pi n}{J}, \quad (6.25) \]

leading finally to

\[ H = \sum_{n=1}^{J/2} \omega_n \left[ \frac{\tilde{c}^\dagger_{n,1} \tilde{c}_{n,1} + \tilde{c}^\dagger_{n,1} \tilde{c}^\dagger_{n,1} + \tilde{c}^\dagger_{n,2} \tilde{c}_{n,2} + \tilde{c}^\dagger_{n,2} \tilde{c}^\dagger_{n,2}}{2} \right], \quad (6.26) \]

where

\[ \omega_n = \sqrt{1 + 4|\alpha_n|} = \sqrt{1 + \frac{4\lambda}{(2\pi)^2} \sin^2 \frac{\pi n}{J}}. \quad (6.27) \]

In this section we have studied giant magnons, but an obvious question is what happens with regular magnons. They will give the usual pp wave (Penrose) limit of the gravity dual. This limit will be studied further in [54].

7 Conclusions

In this paper we have studied various observables for the GJV duality between the warped, squashed AdS$_4 \times S^6$ background and the 3 dimensional $\mathcal{N} = 2$ SYM-CS theory at level $k$ at the fixed point.

We have found that static wrapped D-branes give baryon vertices. At zero magnetic flux, we have D0-brane and D6-brane baryons, as well as their bound states, and they present evidence for the existence of a level-rank duality: besides the baryon vertex for $N$ quarks we also have a baryon vertex for $k$ quarks, and their masses are proportional to $N$ and $k$, respectively, other than the $\lambda^{1/6}$ piece. At nonzero magnetic flux, we have some interesting new baryon vertices that depend on the flux $N$. Brane probes give a gauge coupling proportional to $\lambda^{1/6}$.

Moving wrapped D-branes give giant gravitons, and we have found that we can have a D2-brane wrapped on $\mathbb{CP}^1$ or a D4-brane wrapped on $\mathbb{CP}^2$, both moving in the transverse $\eta$ (or $\psi$) direction. They correspond as usual to subdeterminant (or more generally Schur polynomial) operators.

Entanglement entropy, calculated from the holographic prescription generalizing the one of Ryu and Takayanagi, gives nothing new with respect to AdS space, other than a renormalization of the Newton’s constant. Wilson loops and the anomalous dimensions of operators of large spin are obtained from long strings in the dual, and both are proportional to $\lambda^{1/3}$.

Finally, giant magnons are found, also long strings in an $S^2$ subspace of the geometry, that correspond to spin chain operators in the field theory. Their Hamiltonian
gives the same eigenergies as coming from the string calculation, and the same as in
the 4 dimensional SYM case.

The GJV duality has many more important issues to be studied. A novel one is
the level-rank duality discovered here. Others, like the Penrose limit, will be studied
elsewhere [54]. It seems like this is just the tip of an iceberg, that should see many
new developments in the near future.

A Conventions

The metric of the space $\text{AdS}_4$, normalized as $R^\text{AdS}_4 = -3g^\text{AdS}_4$, is
\[
\frac{ds^2_{\text{AdS}_4}}{u^2} + u^2 dx^\mu dx_\mu = \frac{1}{y^2}(dy^2 + dx^\mu dx_\mu) = -(1 + r^2)dt^2 + \frac{dr^2}{1 + r^2} + r^2 d\Omega^2,
\]
(A.1)
or in global coordinates
\[
\frac{ds^2_{\text{AdS}_4}}{\lambda^2} = \cosh^2 \rho dt^2 + d\rho^2 + \sinh^2 \rho d\Omega^2,
\]
(A.4)
where $d\Omega^2 = dv^2 + \sin^2 \vartheta d\phi^2$ with $v \in [0, \pi]$ and $\varphi \in [0, 2\pi]$, defines a two sphere $S^2$.

In addition, the metric of the complex projective space $\mathbb{CP}^2$, normalized in such
a way that $R^\mathbb{CP}^2 = 6g^\mathbb{CP}^2$, see [46, 55], is
\[
ds^2_{\mathbb{CP}^2} = d\lambda^2 + \frac{1}{4} \sin^2 \lambda \left\{ \theta^2 + \sin^2 \theta d\phi^2 + \cos^2 \lambda (d\sigma + \cos \theta d\phi)^2 \right\} = d\lambda^2 + \frac{1}{4} \sin^2 \lambda \left\{ \Sigma^2_1 + \Sigma^2_2 + \cos^2 \lambda \Sigma^2_3 \right\}
\]
(A.5)
where $0 \leq 2\lambda, \theta, \phi/2, \sigma/4 \leq \pi$. In this coordinate system, the Kähler potential can be written as
\[
\omega = \frac{\sin^2 \lambda}{2} (d\sigma + \cos \theta d\phi),
\]
(A.7)
with Kähler-form $\mathcal{J} = \frac{1}{2} d\omega$ and volume form $\text{vol}(\mathbb{CP}^2) = \frac{\pi^2}{2} \mathcal{J} \wedge \mathcal{J}$ and the volume of $\mathbb{CP}^2$ is $\int \text{vol}(\mathbb{CP}^2) = \frac{\pi^2}{2}$. Since, for fixed $\sigma$ and $\lambda = \pi/2$ we have a $\mathbb{CP}^1$ then
\[
\int_{\mathbb{CP}^1} \mathcal{J} = -\pi \quad \text{and} \quad \int_{\mathbb{CP}^2} \mathcal{J} \wedge \mathcal{J} = -\pi^2.
\]
(A.8)
Finally, it will be useful to consider the $SU(2)$ symmetry of this metric. Then, we can write the metric in terms of the Maurer-Cartan forms of the group $SU(2)$ given by

\begin{align}
L_1 &= \frac{1}{\sqrt{2}} (-\sin \sigma d\theta + \cos \sigma \sin \theta d\phi) \equiv \frac{1}{\sqrt{2}} \Sigma_1 \\
L_2 &= \frac{1}{\sqrt{2}} (\cos \sigma d\theta + \sin \sigma \sin \theta d\phi) \equiv \frac{1}{\sqrt{2}} \Sigma_2 \\
L_3 &= \frac{1}{\sqrt{2}} (d\sigma + \cos \theta d\phi) \equiv \frac{1}{\sqrt{2}} \Sigma_3.
\end{align}

(A.9)

that satisfies $dL^i = \frac{\epsilon^{ijk}}{\sqrt{2}} L^j \wedge L^k$ and \( \Sigma_1 \wedge \Sigma_2 \wedge \Sigma_3 = \sin \theta d\theta \wedge d\sigma \wedge d\phi \).
