Abstract: Background: The prevalence of hepatitis B varies (HBV) among countries. Although an overall reduction has been described in Greece, data are limited. Methods: We reviewed the HBsAg/anti-HBc/anti-HBs seroprevalence among military recruits and compared data between 2005 and 2019. The study included 2001 (group 1) and 1629 (group 2) male recruits in 2019 and 2005, respectively. Age and descent were recorded. Results: The prevalence of HBsAg, anti-HBc and anti-HBs positivity in group1 vs. group 2 was estimated as: 0.2%, 1.3% and 67% vs. 0.4%, 1.6% and 62%, respectively. Only anti-HBs positivity achieved a statistically significant difference between the two groups ($p = 0.007$). HBsAg and anti-HBc were more frequently positive in non-Greeks than in Greeks (9/237 (4%) vs. 2/3393 (0.06%), $p < 0.001$), (26/237 (11%) vs. 26/3393 (0.8%), $p < 0.001$ respectively), while anti-HBs was more frequently positive in Greeks than in non-Greeks (84/164 (51%) vs. 1461/2213 (66%), $p < 0.001$). Conclusions: Our data suggest a further reduction in HBV prevalence in Greece about 20 years after the adoption of the National HBV Immunization Program, with Greek participants experiencing a more effective HBV Immunization Program than non-Greeks.

Keywords: hepatitis B virus (HBV); HBsAg; anti-HBc; anti-HBs; HBV immunization program

1. Introduction

More than two billion individuals have serologic evidence of hepatitis B virus (HBV) infection worldwide. Despite advances in antiviral therapy, a functional cure is rare. Although the prevalence of hepatitis B surface antigen (HBsAg) varies between European countries, the incidence of HBV has declined over the past ten years from 6.7 cases per 100,000 population in 1995 to 1.5 cases per 100,000 population in 2000. This decline has been achieved mainly due to effective vaccination programs, blood donor control, pre-delivery evaluation of pregnant women, and passive-active immune-prophylaxis treatment of infants born from chronic HBV-infected mothers [1–6].

In the past, Greece has been considered part of a group of European countries with a high burden of HBV as the prevalence of HBsAg positivity was 2–7%. However, although published general population data are limited, nowadays HBV prevalence in Greece seems to be around 2% [7–10]. Moreover, studies on military recruits exhibit a significant decline in HBsAg prevalence, from 4% in 1973 to 0.95% in 1999 and finally to 0.32% in 2005,
mainly due to the modification of economic status and to the successful National HBV Immunization Program (Hellenic National Immunization Program for hepatitis B) that the Hellenic Government adopted in 1998 [11–14].

Migration to Greece from low- and middle-income countries in Eastern Europe with a high prevalence of HBV has increased since the 1990s. The relative contribution of first-generation migrants from intermediate and high-endemicity countries to the overall chronic hepatitis B (CHB) case burden in Greece has been estimated to be 29% [6,15]. This study aimed to examine a possible shift in HBV epidemiology among military young adults between 2005 and 2019 and evaluate potential associations with epidemiological characteristics and HBV vaccination.

2. Materials and Methods

2.1. Study Population

The study sample consisted of 2001 volunteer male recruits (group 1), with a mean age of 21 (range: 18–39) years, who were referred to the Supply and Transportation Corps Training Centre of the Hellenic Army (Sparta, Greece) in 2019 and 1629 volunteer male recruits (group 2), with a mean age of 20 (range: 17–34) years, who were referred to the same Training Center back in 2005. The representativeness of group 2 has been previously presented in [13]. The study was performed according to the World Medical Association Declaration of Helsinki and approved by the Medical Directorate of the Hellenic Army General Staff.

2.2. Laboratory Testing

A venous blood specimen was taken from each subject under aseptic conditions. Sera were evaluated in the Microbiology Laboratory of 401 Army General Hospital of Athens within three hours to process HBsAg, anti-HBs, and anti-HBc using commercially available enzyme immunoassays. Thus, HBsAg and anti-HBc markers were evaluated in all participants, while anti-HBs was assessed in 748/2001 (37.5%) subjects of the first group and in all participants of the second.

All study participants were informed of the test results through personal interviews, while infected patients were referred to 401 Army General Hospital of Athens for further evaluation.

2.3. Definitions

The following different patterns were revealed: (1) HBsAg(+)/anti-HBc(+) as positive HBsAg, (2) HBsAg(−)/anti-HBc(+) as indicative of past HBV exposure, (3) HBsAg(−)/anti-HBc(−)/anti-HBs(+) with a titer > 10 IU/mL as indicative of immunity due to successful HBV vaccination, (4) HBsAg(−)/anti-HBc(+)anti-HBs(+) as indicative of immunity due to natural HBV infection, and (5) HBsAg(−)/anti-HBc(−)/anti-HBs(−) as susceptible subjects [16].

2.4. Data Collection

Personal interviews were conducted to collect epidemiological data regarding age and geographic area of descent. Participants with no available data about age or descent were excluded in both groups. Immunization history with hepatitis B vaccine was obtained by checking the immunization certificate in 723/2001 (36%) participants of group 1.

2.5. Statistical Analysis

All data were analyzed using the statistical package MedCalc (version 18.2). Statistical analysis was performed using the chi-squared test for comparisons of qualitative data between groups. A two-tailed p-value < 0.05 was considered to be statistically significant.
3. Results

All recruits in group 1 and group 2 were male, and their mean age was 21.73 ± 2.72 and 20.6 ± 2, respectively. Participants of group 2 were statistically significantly younger than those of group 1 (p < 0.001). Although most subjects were Greek, a statistically significant difference among the two groups was revealed (92.5% vs. 94.5%, p = 0.008 respectively). The vast majority of non-Greek subjects were second-generation migrants from Eastern Europe, mainly Albania. The baseline characteristics of both groups are shown in Table 1.

### Table 1. Baseline characteristics of group 1 and group 2 participants.

| Group   | N, number of participants | Mean age ± SD, years | p-Value |
|---------|---------------------------|----------------------|---------|
| Group 1 | 2001                      | 21.73 ± 2.72         | <0.001  |
| Group 2 | 1629                      | 20.6 ± 2             |         |

| Group of Age, n/N (%) | 17–19 | 20–22 | ≥23  | Greeks, n/N (%) |
|-----------------------|-------|-------|------|-----------------|
| 17–19                 | 543/2001 (27) | 771/2001 (38.5) | 687/2001 (34.5) | 1852/2001 (92.5) |
| 20–22                 | 731/1629 (45) | 605/1629 (37)    | 293/1629 (18)   | 1541/1629 (94.5) |
| ≥23                   | <0.001 | <0.001 | <0.001 | 0.008           |

The number of positive HBsAg patients was: 5/2001 (0.2%) in group 1 and 6/1629 (0.4%) in group 2 (p = 0.364). Subjects with past HBV exposure were: 26/2001 (1.3%) in group 1 and 26/1629 (1.6%) in group 2 (p = 0.271).

Subjects with indicative immunity due to successful HBV vaccination were: 502/748 (67%) in group 1 and 1006/1629 (62%) in group 2 (p = 0.007). To evaluate the long-term immune status after HBV immunization, we further analyzed 723 participants of group 1 who were all vaccinated in childhood against HBV according to their immunization schedule certificate. Finally, 507/723 (70%) of these previously vaccinated participants had protective anti-HBs titers.

Subjects with immunity due to natural HBV infection were: 19/748 (2.5%) in group 1 and 18/1629 (1.1%) in group 2 (p = 0.009). Susceptible subjects were: 220/748 (29.5%) in group 1 and 597/1629 (36.5%) in group 2 (p < 0.001). The results of the above-mentioned serologic analysis are shown in Table 2.

### Table 2. HBV serologic markers among group 1 and group 2 participants.

|                     | Group 1 * | Group 2 | p-Value |
|---------------------|-----------|---------|---------|
| HBsAg(+) / anti-HBc(+) | 5/2001 (0.2) | 6/1629 (0.4) | 0.364   |
| HBsAg(–) / anti-HBc(+) | 26/2001 (1.3) | 26/1629 (1.6) | 0.271   |
| HBsAg(–) / anti-HBc(–) / anti-HBs(+) | 502/748 (67) | 1006/1629 (62) | 0.007   |
| HBsAg(–) / anti-HBc(–) / anti-HBs(–), n/N (%) | 19/748 (2.5) | 18/1629 (1.1) | 0.009   |
| HBsAg(–) / anti-HBc(–) / anti-HBs(–) | 220/748 (29.5) | 597/1629 (36.5) | <0.001  |

* Anti-HBs was evaluated in 748/2001 (37.5%) of the group 1.

Among all participants, HBsAg and anti-HBc were more frequently positive in non-Greeks than in Greeks (9/237 (4%) vs. 2/3393 (0.06%), p < 0.001), (26/237 (11%) vs. 26/3393 (0.8%), p < 0.001, respectively), while anti-HBs was more frequently positive in Greeks than in non-Greeks (84/164 (51%) vs. 1461/2213 (66%), p < 0.001). To exclude the possibility that this finding did not reflect the statistically significant difference in descent between the two groups, we performed the same analysis in each group separately. Nevertheless, even in each group analysis, HBsAg and anti-HBc were more frequently positive in non-Greeks than in Greeks (4/149 (2.5%) vs. 1/1852 (0.05%), p < 0.001), (17/149 (11.5%) vs. 9/1852 (0.5%), p < 0.001) and (5/88 (5.5%) vs. 1/1541 (0.06%), p < 0.001), (9/88 (10.2%) vs. 17/1541 (1.1%), p < 0.001) in group 1 and group 2, respectively, while anti-HBs was more frequently
positive in Greeks than in non-Greeks (41/76 (54%) vs. 480/672 (71.5), \( p = 0.002 \)) and (43/88 (49%) vs. 981/1541 (63.5%), \( p = 0.004 \)) in group 1 and group 2, respectively (Table 3).

**Table 3.** Factors associated with HBsAg, anti-HBc and anti-HBs positivity.

| Descent       | HBsAg Positive, n/N (%) | HBsAg Negative, n/N (%) | anti-HBc Positive, n/N (%) | anti-HBc Negative, n/N (%) | anti-HBs Positive, n/N (%) | anti-HBs Negative, n/N (%) | \( p \)-Value |
|---------------|-------------------------|-------------------------|---------------------------|---------------------------|---------------------------|---------------------------|--------------|
| Both Groups   |                         |                         |                           |                           |                           |                           | <0.001       |
| non-Greeks    | 9/237 (4)               | 228/237 (96)            | 26/237 (11)               | 211/237 (89)              | 84/164 (51)               | 80164/(49)                |              |
| Greeks        | 2/3393 (0.06)           | 3391/3393 (99.94)       | 26/3393 (0.8)             | 3367/3393 (99.2)          | 1461/2213 (66)            | 752/2213 (34)             | <0.001       |
| Group 1 *     |                         |                         |                           |                           |                           |                           | <0.001       |
| non-Greeks    | 4/149 (2.5)             | 145/149 (97.5)          | 17/149 (11.5)             | 132/149 (88.5)            | 41/76 (54)                | 35/76 (46)                |              |
| Greeks        | 1/1852 (0.05)           | 1851/1852 (99.95)       | 9/1852 (0.5)              | 1843/1852 (99.5)          | 480/672 (71.5)            | 192/672 (28.5)            |              |
| Group 2       |                         |                         |                           |                           |                           |                           | <0.05        |
| non-Greeks    | 5/88 (5.5)              | 83/88 (94.5)            | 9/88 (10.2)               | 79/88 (89.8)              | 43/88 (49)                | 45/88 (51)                |              |
| Greeks        | 1/1541 (0.06)           | 1540/1541 (99.94)       | 17/1541 (1.1)             | 1524/1541 (98.9)          | 981/1541 (63.5)           | 560/1541 (36.5)           |              |

* Anti-HBs was evaluated in 748/2001 (37.5%) of the group 1.

Age, either as a quantitative or as a qualitative variable, was not associated as a prognostic factor of any HBV serology marker in both groups of participants.

4. Discussion

The primary scope of our study was to determine the prevalence of seropositivity for HBsAg during the last 14 years. In 2005, HBsAg seroprevalence among military recruits was estimated at 0.4% [13]. Furthermore, we documented a further reduction as we have an estimated HBsAg seropositivity prevalence of 0.2% in 2019. Although this finding is not statistically significantly different among the two groups of participants, it confirms a continuing trend in the reduction in HBsAg positivity prevalence in Greece about 20 years after the adoption of universal immunization against HBV in the Greek population [11]. In 1971, HBsAg positive prevalence in military recruits was estimated as 4.9%, while in 1998, in a similar military population it was 0.95% [11,17]. General population published data are limited in Greece, whereas the best-studied group is that of blood donors. In 1999, a large population study of blood donors on the island of Crete for five consecutive years revealed that the mean prevalence of HBsAg was 0.4% [8]. Only one published study concerning the general population has been conducted in the region of South-Western Greece in 2002 and it revealed a seroprevalence for HBsAg positivity of 2.1% [7]. Although our study’s results cannot be extrapolated to women or high-risk populations such as people who inject drugs (PWIDs), sex workers, multi-transfused patients, or patients in hemodialysis, it included a significant number of second-generation migrants from high-prevalence HBsAg positive areas of Eastern Europe [10,18]. Although non-Greek participants were more likely to be HBsAg and/or anti-HBc positive than Greeks, they did not seem to significantly modify the epidemiological data, as the prevalence of HBsAg positivity in group 1 was only 0.2%. Thus, we believe that our results, even with the limitations of the selected included population, are consistent with an overall reduction in HBV prevalence in Greece [19].

The key to this reduction in HBsAg positivity seems to be the effective Hellenic National Immunization Program for hepatitis B, which was adopted in 1998 and included all infants and all 12-year-old children at that time. As the mean age of participants in group 1 was 21.73 ± 2.72 years old, most of them were born around 1998. Thus, most of them should have been vaccinated against HBV. Indeed, we found that 67% of these subjects had an adequate titer of anti-HBs. Moreover, among a sub-group of 723 participants with a certificate proving vaccination, 507 of them (70%) had protective anti-HBs levels, which are the highest mentioned in the literature [20–23]. Interestingly, we found that group 2, aged 20.6 ± 2 years old, who were born around the middle of the 1980s, also achieved an adequate anti-HBs titer of 62%, which is consistent with the successful immunization
program of all 12-year-old children in 1998 mentioned above. However, a statistically significant difference in protective anti-HBs titer favors group 1 participants, which is compatible with a more effective vaccination program in those who were born in Greece in the late 1990s. This finding underlines the significant role of migrants in the epidemiology of HBV infection as >45% of non-Greek participants in both groups were more likely to be susceptible to HBV infection due to non-vaccination.

5. Conclusions
In conclusion, our data suggest a further reduction in HBV prevalence in Greece. Moreover, the Hellenic National Immunization Program for hepatitis B seems to have been largely successful in reducing the prevalence of hepatitis B infection and it has increased the immunity levels in the population. However, the migration of people from countries of high endemicity may contribute to a modification of the epidemiological data. Since the most effective means of prevention against HBV is vaccination, health care professionals should raise awareness about hepatitis B and encourage adherence to guidelines according to the National Immunization Program for hepatitis B [24].
