ABSTRACT. In this article we show the following: Let \( \Pi \) be a translation plane of even order \( q^2 \) that admits \( GL(2,q) \) as a collineation group. Then \( \Pi \) is either Desarguesian, Hall or Ott-Schaeffer.

KEY WORDS AND PHRASES. Translation planes, Desarguesian, Hall, Ott-Schaeffer planes.

AMS(MOS) SUBJECT CLASSIFICATION (1970) CODES. 50D05, 05B25.

1. INTRODUCTION.

The author and Ostrom recently studied translation planes \( \Pi \) of even order that admit \( SL(2,2^s), s \geq 1 \). In [10], we considered the case where \( \Pi \) has dimension 2 over its kernel and in [9] no assumption was made concerning the kernel.

Schaeffer [13] has shown that if a translation plane of even order \( q^2 \) whose kernel \( \cong GF(q) \) admits \( SL(2,q) \), then the plane is Desarguesian, Hall
or Ott-Schaeffer.

In [9], it is shown that if the assumption on the kernel is dropped, the planes admitting $SL(2,q)$ must have properties quite similar to the Desarguesian, Hall or Ott-Schaeffer planes but it is an open question whether such planes must, in fact, be in one of these three classes.

In the dimension 2 situation, if the plane admits $SL(2,2^s)$ then the plane also admits $GL(2,2^s)$ (see (2,2)). So, in particular, the Hall and Ott-Schaeffer planes of even order $q^2$ must admit $GL(2,q)$ as a collineation group.

In this paper we observe that this situation can be reversed (see Theorem (2.7)).

We assume the reader is familiar with the papers [9] and [10].

2. THE MAIN THEOREM.

(2.1) NOTE. If $\pi$ is a translation plane of even order with kernel $\geq GF(2^s)$ and admitting $SL(2,2^s)$, $s > 1$, then $\pi$ admits $GL(2,2^s)$ as a collineation group.

PROOF. $GL(2,2^s) = SL(2,2^s) \times \mathfrak{C}$ where $\mathfrak{C}$ is the center of $GL(2,2^s)$. Conversely, if $\pi$ admits a group $SL(2,2^s) \times K$ where $K$ is cyclic of order $2^s-1$, then, by the obvious isomorphism, $SL(2,2^s) \times K$ is isomorphic to $GL(2,2^s)$.

Since the kern homology group $K$ of order $2^s-1$ commutes with elements of the linear translation complement and $SL(2,2^s)$ is linear by [10] (see the proof of (2.1)), we have a group $SL(2,2^s) \times K$ (since $SL(2,2^s)$ is simple).

(2.2) COROLLARY. If $\pi$ is a translation plane of even order $2^{2r} = q^2$ whose kernel contains $GF(q)$ admits $SL(2,2^s)$, $s > 1$, then $\pi$ admits $GL(2,2^s)$.

PROOF. $s \mid r$ by [10] ((2.2) and (2.4)). Thus, there is a cyclic subgroup $\overline{K}$ (of the group of kern homologies) of order $2^s-1$. By (2.1), we have the proof to (2.2).
We also note that (2.2) is not valid for translation planes of odd order (see Foulser [4]).

If a translation plane is of dim 2 then the group \( \mathcal{J} \) in the linear translation complement generated by all Baer involutions is always \( \text{SL}(2, 2^s) \) if there are no elations and the group is nonsolvable (see [10], (3.27)). However, essentially nothing is known concerning the group \( \mathcal{J} \) without assuming that the Baer subplanes are disjoint (as subspaces).

(2.3) THEOREM. Let \( \pi \) be a translation plane of even order admitting a collineation group \( \mathcal{J} \) whose sylow 2-subgroups fix Baer subplanes pointwise.

Let \( Q \) be a sylow 2-subgroup of \( \mathcal{J} \). Then either

1. \( Q \) is normal in \( \mathcal{J} \),
2. \( |Q| = 2 \),

or

3. the subgroup generated by the Baer involutions is \( \text{SL}(2, 2^s) \) for \( s > 1 \).

PROOF. Suppose neither (1) nor (2). Consider \( \eta_\mathcal{J}(Q^x) \cap Q \) (normalizer of \( Q^x \) in \( \mathcal{J} \)) for \( x \in \mathcal{J} \).

Suppose \( g \in \eta_\mathcal{J}(Q^x) \cap Q \) so that \( Q^x g = Q^x \) for \( g \in Q \). Since \( |g| = 2 \) by Foulser ([2], (2.5)), \( g \) must centralize some involution \( h \) of \( Q^x \). Thus, \( \langle g, h \rangle \) is an elementary abelian 2-group and so is contained in a sylow 2-subgroup \( \overline{Q} \).

Let \( Q^x, Q, \overline{Q} \) respectively fix the Baer subplanes \( \pi_1, \pi_2, \pi_3 \) pointwise. Then \( g \in Q \cap \overline{Q} \) so \( g \) fixes \( \pi_2 \) and \( \pi_3 \) pointwise. Thus, \( \pi_2 = \pi_3 \) and similarly \( \pi_1 = \pi_3 \). Thus, \( \langle Q^x, Q \rangle \) fixes \( \pi_1 \) pointwise. By Foulser [3] (Theorem 2), \( \langle Q^x, Q \rangle \) is a subgroup of a one-dimensional affine group. So, the involutions of \( \langle Q^x, Q \rangle \) belong to the same sylow 2-subgroup. Thus \( Q^x = Q \) and \( x \in \eta_\mathcal{J}(Q) \).

Thus, \( \eta_\mathcal{J}(Q^x) \cap Q = \langle 1 \rangle \) for \( x \in \mathcal{J} - \eta_\mathcal{J}(Q) \).
We can thus apply Hering's main theorem of [7]. Let $S$ denote the normal closure of $Q$ in $\mathfrak{K}$. Then $S$ is isomorphic to $\text{SL}(2,2^s)$, $s > 1$, $S_2(2^s)$, $\text{PSU}(3,2^s)$, or $\text{SU}(3,2^s)$. But only $\text{SL}(2,2^s)$ has elementary abelian sylow 2-subgroups which must be the case by Foulser ([2], (2.5)).

Clearly, $S$ is the group generated by the Baer involutions of $\mathfrak{K}$.

(2.4) THEOREM. (Special case of the main theorem of Foulser-Johnson, Ostrom [5].) Let $\pi$ be a translation plane of order $q^2$ which admits $\text{GL}(2,q)$ and where the $p$-elements ($p^r = q$) are elations. Then $\pi$ is Desarguesian.

(2.5) THEOREM. Let $\pi$ be a translation plane of order $q^2 \neq 4$ or 9 which admits $\text{GL}(2,q)$ where the sylow $p$-subgroups, $p^r = q$, fix Baer subplanes pointwise. Then $\pi$ is a Hall plane.

PROOF. If $|\pi|$ is even then by Johnson and Ostrom [9], (4.1), the Baer subplanes fixed pointwise fall into a derivable net $\eta$. Thus, the derived plane is Desarguesian by (2.4) since $\text{GL}(2,q)$ must fix the net. If $|\pi|$ is odd, the Baer subplanes fall into a derivable net by Foulser [2] if $q \neq 3$ (Theorem (5.1)) and thus (2.4) applies.

(2.6) THEOREM. Let $\pi$ be a translation plane of even order $q^2$ which admits $\text{GL}(2,q)$ where the sylow 2-groups fix subsets of order $q$ that are contained in components. Then $\pi$ is an Ott-Schaeffer plane.

PROOF. By [9], (4.6), we have orbits on $I_\infty$ of lengths $q+1$, $\frac{1}{2}q(q-1)$, and $\frac{1}{2}q(q-1)$ under $\text{SL}(2,q)$.

Let $\sigma$ be in the center of $\text{GL}(2,q)$. Then $\sigma$ must fix each Baer subplane which is fixed pointwise by an involution and must fix each line of the orbit of length $q+1$.

The $q-1$ Baer subplanes fixed pointwise by elements of a sylow 2-group of $\text{SL}(2,q)$ cover the components other than the components in the orbit of length $q+1$. 
Let $\prod_{i=1}^{\lambda} p_i^{\alpha_i}$ be the prime decomposition of $q-1$ and let $\sigma_i$ be an element of order $p_i^{\alpha_i}$. Then, since $\sigma_i$ fixes each Baer subplane $\pi_j$ indicated above and $\pi_j$ shares precisely one component with the orbit of length $q+1$, $\sigma_i$ fixes a component from each Baer subplane $\pi_j$ and so fixes each component of $\pi$. Thus, $\prod_{i=1}^{\lambda} \sigma_i = \sigma$ fixes each component of $\pi$. Therefore, $\pi$ has $\dim 2/\ker \sigma$ so that $\pi$ is an Ott-Schaeffer plane by Schaeffer.

We can now state our main theorem.

(2.7) **Theorem.** Let $\pi$ be a translation plane of even order $q^2$ which admits $\text{GL}(2,q)$ as a collineation group. Then the fixed point space of each Sylow 2-subgroup is a component, Baer subplane, or Baer subline and

(i) $\pi$ is Desarguesian if and only if the Sylow 2-subgroups fix components pointwise,

(ii) $\pi$ is Hall if and only if the Sylow 2-subgroups fix Baer subplanes pointwise,

(iii) $\pi$ is Ott-Schaeffer if and only if the Sylow 2-subgroups fix Baer sublines (sublines of order $q$) pointwise.

**Proof.** By (2.3), (2.4), (2.5), and (2.6), it remains to show that the fixed point spaces are as asserted. We can thus assume that the involutions are Baer. We can assume that a Sylow 2-subgroup $Q$ does not pointwise fix a component, Baer subplane, or Baer subline. Let $Q$ fix $X$ pointwise.

Let $\mathcal{C}$ denote the center of $\text{GL}(2,q)$.

**Case 1:** The center is fixed-point-free.

Let $\mathcal{C} = \langle \sigma \rangle$. Then, if $P \in X$, $\sigma^P \in X$. If $X$ intersects, nontrivially, a line fixed by $\sigma$ then $Q$ fixes $\ge q$ points of a component. So, assume $X$ does not nontrivially intersect any component fixed by $\sigma$.

Obviously then $X$ cannot lie on a component of $\pi$ and is thus a subplane of order $2^s$. If $p \in Q$ and fixes the Baer subplane $\pi_p$ pointwise then $X$
is a subplane of $\pi_p$. Thus, $2^8 \leq \sqrt{q}$ (since $X \neq \pi_p$ by assumption). Let $L$ be a component of $X$ and $\langle \sigma^i \rangle$ the stabilizer of $L$ in $\langle \sigma \rangle = \delta$. Thus, $|\langle \sigma^i \rangle| \leq 2^8 - 1$ since $\delta$ is fixed-point-free and the $\delta$-orbit of $L$ has length $2^8 + 1$ since $\delta$ fixes $X$ and $X$ has $2^8 + 1$ components. So, 

$q - 1 \leq (2^8 - 1)(2^8 + 1) = 2^{2s} - 1 \leq q - 1$ so that $X$ has order $\sqrt{q}$ and the orbit length of $L$ is $\sqrt{q} + 1$.

By Foulser ([3] (Theorem 2)), $Q|\pi_p$ has order $\leq \sqrt{q}$. Let $Q$ be the maximal subgroup of $Q$ which fixes $\pi_p$ pointwise. Then $|Q| \geq \sqrt{q}$. If $q = 4$ then $|Q| = 2$. If $\sqrt{q} > 2$, $\langle Q, Q^x \rangle \cong SL(2, \sqrt{q})$ or $SL(2, q)$ by [9](2.1) for some $x \in GL(2, q)$. That is, if $Q$ and $Q^x$ are in distinct Sylow 2-subgroups then $\langle Q, Q^x \rangle \cong SL(2, 2^s)$ for some $s \geq 1$. Since $|Q| \geq \sqrt{q}$, $2^s \geq \sqrt{q}$.

But, $\langle Q, Q^x \rangle \cong SL(2, q)$ so $2^s = \sqrt{q}$ or $q$. By [9](2.9), we know that $|Q| = \sqrt{q}$.

Let the normalizer of $Q$ in $SL(2, a)$ be $QC$. $Q$ fixes $\pi_p$ pointwise so there is a subgroup $C$ of $C$ of order $\sqrt{q} - 1$ that fixes $\pi_p$. Moreover, since $\delta$ is transitive on the points of $X$ and $C$ permutes the points fixed by $Q$, we have that if $C = \langle \sigma \rangle$ then there is an element $g$ of $\delta$ such that $Qg$ fixes a point of $X$ and thus fixes $X$ pointwise.

Let the fixed point subplane of $\langle Qg \rangle$ be $\pi$.

Now there are $\sqrt{q} + 1$ distinct subgroups $Q_i$ of $Q_i$ each fixing $X$ pointwise and also fixing pointwise a Baer subplane $\pi_i$. ($C$ is regular on the involutions of $Q \setminus \{1\}$.) That is, $Q = \left( \bigcup_{i=1}^{\sqrt{q}+1} Q_i \setminus \{1\} \right) \cup \{1\}$.

Suppose $L$ is a component not in $X$ common to $\pi_i$ and $\pi_j$. Then $\langle Q_i, Q_j \rangle$ fixes $L$ and fixes $X$ pointwise and thus fixes a Baer subplane pointwise. Hence, $\pi_i$ and $\pi_j$ share no components outside of $X$.

So there are $(\sqrt{q} + 1)(q - \sqrt{q})$ components that are permuted by $C = \langle \sigma \rangle$. [9]
Since $\mathcal{G}$ fixes each subplane $\pi_1$ and also leaves $X$ invariant, $\mathcal{G}$ fixes $\pi_1-X$ and thus permutes the same set of components.

So, $\langle \mathcal{G} \rangle$ permutes the remaining set $\mathcal{J}$ of $q^2+1-(\sqrt{q}+1)(q-\sqrt{q})+\sqrt{q}+1)$ components $= q\sqrt{q}(\sqrt{q}-1)$.

Let $Q^X$ fix a subplane $Y$ of order $\sqrt{q}$ pointwise. If $X \cap Y \neq \emptyset$ then $X = Y$ since $\mathcal{G}$ is regular on $X-O$ and fixes $X$ and $Y$. But, $\langle Q^X, Q \rangle \cong SL(2,q)$ then fixes $X$ pointwise, contrary to [9] (4.3).

If $X$ and $Y$ share a component then they share $\sqrt{q}+1$ components.

Since $Q$ fixes $X$ pointwise, $Q$ maps $Y$ onto $q$ other pairwise disjoint subplanes of order $\sqrt{q}$ which are pointwise fixed by the $q$ other Sylow 2-subgroups. (By [9] (4.3), it follows that $GL(2,q)$ acts on these sets of subplanes of order $\sqrt{q}$ as it acts on the Sylow 2-subgroups.) Thus, each of the $q+1$ subplanes is on the same set of $\sqrt{q}+1$ components. Thus, $\langle Q, Q^X \rangle$ fixes each of these components. $\mathcal{G} \cong SL(2,q)$ fixes each of $\sqrt{q}+1$ components and permutes the remaining set $\mathcal{J}$ of $q^2-\sqrt{q}$ components. Let $\rho \in \mathcal{J} \cap |\rho|$ is 2-primitive. Then $\langle \rho \rangle$ and $\langle \rho^X \rangle$ cannot fix a common component $\mathcal{L}$, for otherwise $\langle \rho, \rho^X \rangle = \mathcal{G}$ fixes $\mathcal{L}$ and a Sylow 2-subgroup fixes a Baer subplane pointwise. Let $\rho$ fix $k$ components of $\mathcal{J}$ so $k$ is odd. There are $\frac{1}{2}q(q-1)$ conjugates of $\rho$, none of which can fix any of these $k$ components. So there is an orbit under $\mathcal{G}$ of length $\frac{1}{2}q(q-1)k^*$ where $k^*$ is odd (the normalizer of $\rho$ contains an involution $\tau$ which must fix one of these $k$ components). So $\tau$ fixes a component $\mathcal{L}$ of $\mathcal{J}$ and fixes a Baer subplane $\pi_\tau$ pointwise. Clearly, the Sylow 2-subgroup containing $\tau$ must have a subgroup of order $\sqrt{q}$ fixing $\pi_\tau$ pointwise. Unless, $\sqrt{q} = 2$, we have a contradiction. However, we have considered planes of order 16 in [11] and this possibility does not occur.

Thus, $X$ and $Y$ do not share a component. Thus, $\langle Q \rangle$ fixes $Y$
(C fixes two subplanes X and Y if C normalizes Q and Q^X) and fixes X pointwise. So the elements in \langle \alpha \rangle of prime power order \sqrt[1]{q}-1 must fix a component of Y and thus fix a Baer subplane pointwise \Pi. So \langle \alpha \rangle must fix \Pi and by Foulser [3] (Thm. 2) there is a subgroup \mathcal{C} of order \geq \sqrt[1]{q+1} fixing \Pi pointwise. (That is, \langle \alpha \rangle fixes pointwise a Baer subplane X of \Pi so \langle \alpha \rangle \Pi \lessgtr \sqrt[1]{q}-1.) Let \sqrt[1]{q}-1 = \prod p_i^{\alpha_i} be the prime decomposition. There exist elements \beta_1 of order p_i^{\alpha_i} in \langle \alpha \rangle which fix Baer subplanes \langle \alpha \rangle Y \Pi_{\beta_1} pointwise. Each \Pi_{\beta_1} is fixed pointwise by a subgroup \mathcal{C} of order \sqrt[1]{q+1} (by uniqueness of subgroups of \langle \alpha \rangle of a given order). Thus, \Pi_{\beta_1} = \Pi. So \Pi_{\beta_1} \Pi_{\beta_1} \Pi pointwise. Let \beta be the element of order \sqrt[1]{q+1}. Thus, \Pi_{\beta_1} \Pi_{\beta_1} \Pi = \alpha \Pi_{\beta_1} \Pi pointwise.

We assert that Y \subset \Pi. If not, then \langle \alpha \rangle fixes Y and acts faithfully on Y. Since \mathcal{C} is regular on Y-\{\mathcal{O}\}, no element of \langle \alpha \rangle can fix a point of Y. Since the elements of order dividing \sqrt[1]{q}-1 fix a component of Y, we must have that \langle \alpha \rangle fixes a component of Y and thus cannot act faithfully on Y. That is, \Pi and Y must share a component.

Let \tau be an involution that maps X \leftrightarrow Y. Thus \Pi and \Pi \tau both contain X and Y. Since X \cap Y = \emptyset, \Pi = \Pi \tau (X and Y are r-dim subspaces of \Pi and \Pi \tau).

Note that Q \leftrightarrow Q^X since X \leftrightarrow Y. Thus, \langle \tau, C \rangle stabilizes \{Q, Q^X\} and is thus dihedral of order 2(q-1)=\mathcal{D}_q-1. Thus \sigma^\tau = \sigma^{-1} and \langle \alpha \rangle^\tau = \sigma^{-1} \alpha. Since \sigma^{-1} \alpha also fixes \Pi pointwise, then \sigma^{-1} \alpha = \alpha \Pi = \alpha \Pi \Pi pointwise. Since g^2 \in \mathcal{C}, g^2 = 1 and thus g = 1.

So \langle \alpha \rangle = C fixes \Pi pointwise. Let the q+1 subplanes of order \sqrt[1]{q} fixed pointwise by the Sylow 2-subgroups be denoted by \Pi_{X_1}, \Pi_{X_2}, \cdots, \Pi_{X_{q+1}}. Let \Pi_{X_i} be the Baer subplane containing \Pi_{X_i} and fixed pointwise by the
cyclic subgroup $C_{1,j}$ of SL(2,q). (Recall that SL(2,q) is 3-transitive on its Sylow 2-subgroups and thus on the subplanes $\{X_i\}$.)

Note that $\Pi$ contains precisely $X$ and $Y$, for otherwise $\Pi$ would contain all $q+1$ subplanes of order $\sqrt{q}$ as $C$ is regular on remaining subplanes $\neq X$ or $Y$.

We assert that $\pi_{X_1,X_2}$ and $\pi_{X_1,X_j}$, $j \neq 2$, share only the components of $X_1$.

**PROOF.** If the subplanes share a component $z$ then $\langle z, X_1 \rangle$ is a Baer subplane (smallest subplane properly containing $X_1$ has order $(\sqrt{q})^2$) so $\pi_{X_1,X_2} = \pi_{X_1,X_j}$, $j \neq 2$, but then $X_1, X_2, X_j$ are in $\pi_{X_1,X_2}$, contrary to the above.

We also assert that $\pi_{X_1,X_2}$ and $\pi_{X_3,X_4}$ share no common component.

**PROOF.** Let $z$ be a common component. Then $\langle C_{1,2}, C_{3,4} \rangle$ fixes $z$ since $C_{1,2}$ fixes $\pi_{X_1,X_2}$ pointwise. Note that $q > 4$. That is, since $X_1$ and $X_2$ share no common components $q+1 \geq 2(\sqrt{q}+1)$. So

- $C_{1,2}$ is regular on $\{X_3, \ldots, X_{q+1}\} = \mathcal{S}_{1,2}$
- $C_{3,4}$ is regular on $\{X_1, X_2, X_3, \ldots, X_{q+1}\} = \mathcal{S}_{3,4}$.

Since $q > 4$, $\mathcal{S}_{1,2} \cap \mathcal{S}_{3,4} \neq \emptyset$ so that there is an orbit of length $q+1$. Thus, $(q+1)(q-1) | |\langle C_{1,2}, C_{3,4} \rangle|$. By examination of the subgroups of SL(2,q), it follows that $\langle C_{1,2}, C_{3,4} \rangle \cong SL(2,q)$.

So SL(2,q) fixes $z$ and acts faithfully on $z$. Then the Sylow 2-subgroups $Q_i$ fix subspaces of $z$ pointwise. Thus, $X_i$ intersects $z$ for each $i$. But, this is a contradiction.

We consider $\pi_{X_1,X_j} - \{X_1, X_j\}$ and $\pi_{X_k,X_m} - \{X_k, X_m\}$. By the above two statements, there are no common components if $[i,j] \neq [k,m]$. We thus may count the components of $\bigcup_{i,j} (\pi_{X_1,X_j} - \{X_1, X_j\})$, for the $\frac{q(q+1)}{2}$ unordered
pairs \((i, j)\), as \(\frac{q(q+1)}{2}(q+1-2(\sqrt{q}+1))\). We also have \(\bigcup_{i=1}^{q+1} X_i\), so we must have at least \((q+1)(\sqrt{q}+1)\) additional components. Therefore, \(q^2+1 \geq \frac{q(q+1)}{2}(q+1-2(\sqrt{q}+1))+(q+1)(\sqrt{q}+1)\) and \(q>4\) which is clearly a contradiction unless \(q+1-2(\sqrt{q}+1)<2\Rightarrow q=2\). So Case 1 is completed.

Case 2: The center \(\mathcal{A}\) is not fixed-point-free. Let \(\rho \in \mathcal{A} \setminus \langle 1 \rangle\) fix pointwise a set of affine points \(\mathcal{J} \neq \emptyset\). \(\langle \rho \rangle\) is characteristic in \(\mathcal{A}\) and \(\mathcal{A}\) is normal in \(\text{GL}(2,q)\). So \(\text{SL}(2,q)\) fixes \(\mathcal{J}\).

Case 2a: \(\mathcal{J}\) is a subplane of order \(2^s\).

So \(\text{SL}(2,q)\) permutes \(2^s+1\) components and unless \(2^s+1 \geq q+1\), \(\text{SL}(2,q)\) must fix each component (see (8.23), p. 214 [8]). So, if \(2^s+1 < q+1\) then \(\text{SL}(2,q)\) must fix pointwise each set of \(2^s < q\) affine points on each of the components of \(\mathcal{J}\). That is, \(\text{SL}(2,q)\) must fix \(\mathcal{J}\) pointwise, which is a contradiction to [9] (4.3). So, \(2^s+1 \geq q+1\) or \(2^s = q\). Thus, \(\text{SL}(2,q)\) fixes a Baer subplane \(\mathcal{J}\) (since some element of \(\mathcal{A}\) fixes it pointwise).

\(\text{SL}(2,q)\) is faithful on \(\mathcal{J}\) by [9] (4.2) so \(\mathcal{J}\) is Desarguesian by Lüneburg [11] Satz 4 and the Sylow 2-subgroups of \(\text{SL}(2,q)\) act as elations on \(\mathcal{J}\). That is, the 2-groups either fix Baer subplanes or Baer sublines pointwise. Thus, we must have

Case 2b: \(\mathcal{J}\) is not a subplane so \(\mathcal{J}\) is contained in a component.

Assuming \(\mathcal{J}\) is prime, \(\rho\) fixes exactly two components, say \(x=0\) and \(y=0\). Thus, \(\mathcal{A}\) must fix both \(x=0\) and \(y=0\) and \(\text{GL}(2,q)\) must also fix \(x=0\) and \(y=0\).

Let \(\theta\) be an element such that \(\mathcal{J}\) is a prime 2-primitive divisor of \(q^2-1\) (which exists by [1] unless \(q=8\) and since \(q\) is assumed to be square this case does not come up). Then \(\theta\) is irreducible on any component \(\mathcal{J}\) fixes.

That is, \(\theta\) either fixes \(\mathcal{J}\) pointwise or is fixed point-free on \(\mathcal{J}\).
(since $\theta$ is completely reducible on $\mathcal{L}$ if $\theta$ fixes a subspace $\mathcal{R}$ of $\mathcal{L}$ pointwise then $\mathcal{R} \oplus \overline{\mathcal{R}} = \mathcal{L}$ implies $\theta$ fixes $\overline{\mathcal{R}}$ pointwise).

Thus, $\theta$ must fix $\mathcal{J}$. So we may take $\mathcal{J}$ to be $x = 0$. Thus, $\rho$ is a $((0), x=0)$-homology.

That is, either $\mathcal{J} = \mathcal{L}$ or $\mathcal{J} \not= \mathcal{L}$ and every prime 2-primitive divisor element fixes $\mathcal{J}$ pointwise. Since $\text{SL}(2,q)$ is simple and fixes $\mathcal{J}$, either $\text{SL}(2,q)$ fixes $\mathcal{J}$ pointwise or is faithful on $\mathcal{J}$. The first alternative cannot exist by [9] (4.2). So $\text{SL}(2,q)$ is faithful on $\mathcal{J}$ and thus $\mathcal{J} = \mathcal{L}$.

If $\mathcal{J}$ is f.p.f. on $y = 0$ then since $\text{SL}(2,q)$ fixes $y = 0$, we may apply our previous argument of Case 1. That is, a Sylow 2-subgroup $Q$ of $\text{SL}(2,q)$ must fix a subspace $\mathcal{X}$ of $\mathcal{L}$ pointwise. Since $\mathcal{J}$ is f.p.f. on $y = 0$ and fixes $\mathcal{X}$, then $|\mathcal{X}| \geq q$ contrary to our assumptions.

Thus, our argument shows that the group $\mathcal{J}$ induces on $x = 0$ ($y = 0$) is semiregular of order $|B| (|A|)$ if $\mathcal{J}$ is represented by $(x, y) \to (xA, yB)$. Thus, $|\mathcal{J}| = q^2 - 1 = \text{LCM}(|A|, |B|)$. Since $\text{SL}(2,q)$ fixes $x = 0$ and $y = 0$, a Sylow 2-subgroup fixes a subplane $\pi_{\mathcal{J}}$ of order $2^s$ pointwise where $2^s < q$.

But, $\mathcal{J}$ fixes $\pi_{\mathcal{J}} \cap (x=0)$ so $|B| \leq 2^s - 1$ and similarly $|A| \leq 2^s - 1$ so $\text{LCM}(|A|, |B|) \leq 2^s - 1$ which implies $q \leq 2^s$.

Thus, we have the proof to our theorem.

ACKNOWLEDGMENT. The author gratefully acknowledges the helpful suggestions of Professor D. A. Foulser in the preparation of this article.
