Abstract

Cerebrovascular diseases are significant causes of death and disability in humans. Improvements in diagnostic and therapeutic approaches strongly rely on adequate gyrencephalic, large animal models being demanded for translational research. Ovine stroke models may represent a promising approach but are currently limited by insufficient knowledge regarding the venous system of the cerebral angioarchitecture. The present study was intended to provide a comprehensive anatomical analysis of the intracranial venous system in sheep as a reliable basis for the interpretation of experimental results in such ovine models. We used corrosion casts as well as contrast-enhanced magnetic resonance venography to scrutinize blood drainage from the brain. This combined approach yielded detailed and, to some extent, novel findings. In particular, we provide evidence for chordae Willisii and lateral venous lacunae, and report on connections between the dorsal and ventral sinuses in this species. For the first time, we also describe venous confluences in the deep cerebral venous system and an ‘anterior condylar confluent’ as seen in humans. This report provides a detailed reference for the interpretation of venous diagnostic imaging findings in sheep, including an assessment of structure detectability by in vivo (imaging) versus ex vivo (corrosion cast) visualization methods. Moreover, it features a comprehensive interspecies-comparison of the venous cerebral angioarchitecture in man, rodents, canines and sheep as a relevant large animal model species, and describes possible implications for translational cerebrovascular research.

Introduction

Cerebrovascular diseases such as ischemic stroke and cerebral venous thrombosis (CVT) are major causes of mortality and neurological disabilities in adulthood. Thrombolysis is the most important and sometimes only therapeutic option for occlusive cerebrovascular diseases. While the treatment is restricted by a relatively narrow time window and a number of contraindications [1] in ischemic stroke, its use for cerebrovascular thrombosis remains a matter of debate [2,3]. Thus, there is an unmet need for additional therapeutic options to arise from preclinical research. Predictive animal models are crucial to assess the safety and efficacy of novel therapeutic approaches for human patients [4]. During the last decade, large animal models of cerebrovascular diseases [5,6] and neurosurgical interventions [7] became increasingly relevant. In particular, a number of sheep models emerged [8,9] since this species was found highly practicable for translational research. Among such models, experimental middle cerebral artery occlusion has been described [10,11] and, consequently the intracranial ovine arterial angioarchitecture has been studied in detail [12,13]. However, little is known about the venous drainage in the sheep although important anatomical differences to other species including humans may limit the use of ovine cerebrovascular disease models. Since profound anatomical knowledge is an important prerequisite for translational research, the present study aimed to provide an in-depth analysis of the ovine intracranial venous blood system and its connections to extracranial veins. Beyond a detailed anatomical description including hitherto unknown structures in sheep and a comprehensive inter-species comparison of the venous vasculature, this study evaluates the applicability and accuracy of clinical imaging techniques to provide a reliable reference for further translational research on cerebrovascular pathologies in this species.
Materials and Methods

Ethics Statement and Vascular Corrosion Casting

All animal experiments (n = 14) were approved by the responsible federal animal welfare authority at the Regional Board Saxony, Detachment Leipzig, Department 24: veterinary affairs and animal welfare (protocol numbers TVV 33/04 and TVV 26/09) and performed in accordance with the guidelines of the European Convention for the Protection of Vertebrate Animals Used for Experimental and Other Scientific Purposes. Venous corrosion casts were prepared from Merino ewes (n = 10), previously subjected to experimental surgery unrelated to the head and the vascular system. Four additional animals were subjected to both MRI and CT imaging.

Sheep were sacrificed by an intravenous injection of 20% hydroxyl-butyramid, 5% mebezonium iodide, and 0.5% tetracaine hydrochloride (T61, Hoechst Roussel; 0.3 ml/kg body weight). After confirmed death, animals were decapitated between the second and third cervical vertebrae. The external jugular veins were carefully dissected and cannulated with 6-mm metallic bulb-headed cannulas followed by manual injection of methyl methacrylate (Kallocryl; Speiko – Dr. Speier GmbH, Germany). The heads were stored at 4°C for 24 hours to allow polymerisation of the injected resin. Maceration was performed with pepsin-hydrochloric acid and amylase/protease solution (Biozym SE, 10%) at 50°C until all soft tissues were dissolved. Thereafter, the skulls were trepanated and two paramedian bone plates of 9×6 cm were removed.

Magnetic Resonance and Computed Tomography Vascular Imaging

Magnetic resonance venography (MRV) and computed tomography venography (CTV) were performed under general anaesthesia in four additional Merino ewes. Immediately after induction of anaesthesia, sheep were intubated and mechanically ventilated (Servo 900 D ventilator, Siemens, Germany). Table 1 provides details on medication schemes and contrast agents used.

Contrast enhanced MRV was performed using a 3T MRI Scanner (Magnetom Trio, Siemens, Erlangen, Germany) equipped with a surface flex coil. The following imaging parameters were applied: FLASH 3D, TR 3.25 s, TE 1.4 s, flip angle 19, slice thickness 1.2 mm, resulting in a voxel size of 0.5×0.5×1.2 mm.

Table 1. Medication schemes used throughout the study.

| Purpose                          | Drug                        | Supplier          | Application route | Dose/Concentration |
|----------------------------------|-----------------------------|-------------------|-------------------|--------------------|
| Induction of anesthesia          | 2% xylazine hydrochloride   | Ceva Santé Animal | i.v. bolus        | 0.1 mg kg⁻¹        |
|                                  | ketamine hydrochloride      | Medistar          | i.v. bolus        | 4 mg kg⁻¹          |
| midazolam (Midazolam)            | Braun Melsungen             | i.v. bolus        | 0.2 mg kg⁻¹        |
| Inhalation anesthesia (during CTV)| Isoflurane                  | CP Pharma         | ventilation       | 2.0%               |
| Oxygen                           | Linde Medical 035            | ventilation       | 40%               |
| Infusion anesthesia (during MRV) | Midazolam (Midazolam)       | Braun Melsungen   | i.v. infusion     | 0.1 mg kg⁻¹ h⁻¹    |
| Ketamine hydrochloride (Ketamin) | Medistar                    | i.v. infusion     | 2 mg kg⁻¹ h⁻¹     |

Figure 1. Morphology of the dorsal sagittal sinus. (A) Schematic drawing of corrosion cast, dorsal view. (B) Corrosion cast, dorsal view. The dorsal sagittal sinus (DSS) was the major cerebral venous drainage of the dorsal sinus system. Along its course, the DSS received ethmoidal, cerebral, meningeal, and diploic veins from the skull. Its superficial profile showed an axial groove over the whole length and nodular protrusions on the caudal one-third of the DSS (B, arrowheads). (C) Corrosion cast, lateral left view. The confluences of the dorsal cerebral veins (DCV) with the DSS showed pinhead-like openings called lateral venous lacunae (LVLs; A, C, D, E) and providing cerebrospinal fluid drainage into the venous system. (D) MRV, coronal section (maximum intensity projection of E, green). (E) MRV, sagittal section. The LVLs are interlinked between the DCV and the DSS in two different sections of MRV. DCV: dorsal cerebral vein, DSS: dorsal sagittal sinus, EV: ethmoidal vein, LVLs: lateral venous lacunae, SIS: sigmoid sinus, TeS: temporal sinus, TrS: transverse sinus. doi:10.1371/journal.pone.0092990.g001
CTV was performed with a 64 channel MDCT (Brilliance 64, Philips Healthcare, Hamburg, Germany) under the following imaging parameters: 0.8 mm slice thickness, 0.4 mm increment, 120 kV, 300 mAs, resulting in a voxel size of 0.5 × 0.5 × 0.8 mm. Imaging reconstructions and further processing were conducted using the Osirix 2.8 freeware (Osirix, Geneva, Switzerland).

Comparison of Structure Detectability

To investigate sensitivity and specificity of corrosion casts and MRV, a semi-quantitative score system was applied. The visualization of venous structures was categorized as not detectable (−), barely visible (+), moderately visible (+++) and distinctly visible (+++). In cases not allowing clear interpretation, CTV was performed as an independent imaging modality.

Results

All structure designations and abbreviations are given in table S1, providing termini as used in the Nomina Anatomica Veterinaria (NAV) and in both the Nomina Anatomica (NA) and the Terminologia Anatomica (TA).

Morphology of the Dorsal Sagittal Sinus

The dorsal sagittal sinus (DSS, Fig. 1A, 1B) collects blood from the dorsal parts of the brain and skull. It originates at the crista galli of the ethmoid bone (Fig. 1B) and runs within the falx cerebri to the internal occipital protuberance (Fig. 1B, 1C; for MRV see Fig. 7B). Corrosion casts unveiled a longitudinal median groove over its entire course. Nodular protrusions were seen in the caudal third, but not in the rostral part (Fig. 1B). Corrosion casts also provided evidence of trabecular structures (chordae Willisii) within the DSS, which prevented a complete filling of the vascular lumen. Due to those structures, discrete foci of contrast agent filling defects were detected in axial MRV projections (Fig. 6B). The DSS received inflow from the ethmoidal veins (EV) (rostrally; Fig. 1A–1C; for MRV see Fig. 5B and Fig. 6D), the dorsal cerebral veins (DCV) (laterally; Fig. 1A–1D; for MRV see Fig. 5C and Fig. 6B) and both diploic and meningeal veins (dorsally). DCV were connected to lateral, pinhead-size expansions of lateral venous lacunae (LVLs) of the DSS (Fig. 1A, 1C–1E). The DSS received the straight sinus (SS) and split into the bilateral transverse sinus (TrS) (Fig. 1A, 1B). This point of venous confluence is called confluence of sinuses (Fig. 2C, 2D).

Deep Cerebral Venous System

Both thalamostriate veins (TSVs) were identified by their convergent, dorsally convex course in a rostromedial direction in corrosion casts and MRV images. It was clearly visible in corrosion casts that each TSV received further venous input from the vein of the septum pellucidum (VSP) and the thalamostriate vein (TSV). The TSVs received inflow from caudate nucleus veins (VCN; A, B) and from the choroidal vein (ChV; A, B). The TSVs and their continuation into the ICV were convergent, dorsally convex in a rostromedial direction in corrosion casts but not by MRV. Likewise, the VCNs were only visible in corrosion casts where they were found to drain draining into the TSVs from rostral and lateral directions (Fig. 2A, 2B). The coalescence of the TSV and the VSP on each side formed the paired internal cerebral veins (ICV) (Fig. 2A, 2B) at the ‘confluens venosus rostralis’. TSVs and their continuation into the ICV were particularly apparent in MRV images (Fig. 7B–7D). After bending backwards, the ICVs merged into the unpaired great
cerebral vein (GCV) at the ‘confluens venosus caudalis’. Both veins were clearly visible in corrosion casts as well as in MRV. The GCV was found to be about 1.5 mm in diameter and between 7.0 and 8.0 mm in length. It runs caudally between the junctions of the ICVs and the vein of corpus callosum (VCC) (Fig. 2A, 2B). The GCV received input from the paired lateral veins (LV) of the lateral ventricle and the unpaired VCC. The VCC was observed as a large and conspicuous vein of about 4 cm length in corrosion casts (Fig. 2B). It appeared as a very small vessel in CTV (Fig. 2E) and was undetectable in MRV (Fig. 7B). Each LV received three tributaries: a central vein (CeV) taking its course rostrally, a dorsomedial basilar cerebral vein (DMBCV) running ventrally and a rostral ventral cerebellar vein (RVCrV) taking its course caudally (Fig. 2A, 2B). The DMBCV approached the ventral cerebral veins, but no anastomoses between these vessels were observed in our study. The fine LV branches could only be discriminated in corrosion casts, but not by in vivo imaging. After entering the falx cerebri, the GCV continued as the SS which ventrally joined the caudal third of the DSS (Fig. 2A–2D; for MRV see Fig. 5F, 5G; Fig. 7B).

Ventral Cerebral Veins

The basilar cerebral vein (BCV), being situated at the ventral brain base, received inflow from the rostral cerebral vein (RCV) and from the middle cerebral vein (MCV). This situation was clearly visible in corrosion casts (Fig. 3A, 3D), but not in MRV images. In the further course, the rhinal vein (RV) and the piriform lobe vein (PLV) formed a main outflow track which drained to the dorsal petrosal sinus (DPS) together with the BCV (Fig. 3A, 3B). The RCV arose from fine branches in the rostral cranial fossa near the ventral part of the crista galli (Fig. 3A, 3D), run caudally over the orbitosphenoidal crest and merged with the MCV (Fig. 3A, 3D), forming the BCV. The latter started dorsally of the optic canal (Fig. 3A, 3C, 3D). Some minor vessels took their course from the BCV in a ventromedial direction and anastomosed with the cavernous sinus (CS) (AR–BCV+CS) (Fig. 3A, 3B).
3C, for MRV see Fig. 5G) as detected in corrosion casts. The RV proceeded along the cerebral juga on the temporal brain surface (Fig. 3A–3C) and ran in a caudally convex arch, receiving input from the PLV before joining the DPS together with the BCV (Fig. 3A–3C). Despite being clearly detectable in corrosion casts, both veins were barely identifiable on MRV images (Fig. 5D, 5F; Fig. 6D–6G; Fig. 7C–7G). The pontine vein (PV) and the ventral cerebellar veins (VCrV) also joined the DPS. The former emerged at the pontine impression and ran in a caudolateral direction to reach the DPS (Fig. 3A, 3C) rostrally of the confluence of the VCrV (Fig. 3A, 3C). The PV and the VCrV could not be visualized in MRV. The paired DPS joined the ipsilateral transverse sinus and were well detectable in corrosion casts (Fig. 3A–3C), and, to a limited extent, in MRV (Fig. 5H; Fig. 6D–6G; Fig. 7D–7F).

Anastomoses of the Ventral Sinus System

The ventral sinus system encompassed a bilateral system of three main sinuses in the middle and caudal cranial fossae (from rostral to caudal): (1) the cavernous sinus (CS), (2) the ventral petrosal sinus (VPS) and (3) the ventral occipital sinus (VOS) (Fig. 3E, 3F; for MRV see Fig. 5E–5H, 5K; Fig. 6F–6J; Fig. 7B–7E). The paired CS displayed a plexiform structure which extended from the foramen orbitarotundum to the dorsum sellae. The ventral petrosal sinus (VPS) drained into the external jugular vein (EJV). The CS was a clearly visible structure in the sheep. The EJV drained into the external jugular vein (EJV).

Figure 4. Course of the emissary veins of the temporal sinus and the formation of the anterior condylar confluent. (A) 3D CT reconstruction of the head combined with schematic vein drawings (blue), lateral, left view. White frame: inset of B. The ovine extracranial veins can be observed in this view, particularly the outer drainage system of the intracranial veins. (B) 3D CT scan combined with schematic diagram of blue and orange colored veins (interrupted orange vein of temporal sinus shows the invisible part of the sinus in the temporal meatus), lateral view. The temporal sinus (TeS) ran through the temporal meatus and split into two distinct vessels, (1) the first emissary vein (EVRF-1), which left the main opening of the retroarticular foramen and joined the maxillary vein (MV), and (2) the second emissary vein (EVRF-2) which ran next to a tributary canal, passed a tributary foramen, and joined the profundal temporal vein (PTV). (D) Corrosion cast, lateral right view. (E) Corrosion cast, ventrolateral view. The emissary vein of the jugular foramen and the emissary vein of the hypoglossal canal converged towards an extracranial orifice and formed the ‘anterior condylar confluent’ (ACC). The emissary vein of the jugular foramen and hypoglossal canal (EVJHC) merged with an anastomotic ramus of the vertebral vein (AR-VV), to form the craniooccipital vein (COV), which drained into the external jugular vein (EJV). (F) 3D CT scan, ventrolateral view. The ACC is a clearly visible structure in the sheep. ACC anterior condylar confluent, AR-VV anastomotic ramus of the vertebral vein, COV craniooccipital vein, EJV external jugular vein, EVJHC emissary vein of the jugular foramen and hypoglossal canal, EVRF-1: first emissary vein of retroarticular foramen, EVRF-2 second emissary vein of retroarticular foramen, MV maxillary vein, PP pterygoid plexus, PTV profundal temporal vein, STV superficial temporal vein, TeS temporal sinus.
Figure 5. Coronal MRV slices through the head of a sheep after intravenous injection of Gadolinium (Dotarem). (A) Lateral, left view of the ovine brain. Lines delineate the levels of coronal MRV slices, letters correspond to the letters in coronal MRV images; B–K, MRV, coronal sections. The angioarchitecture of the dorsal and ventral sinus systems including their connecting veins was clearly depicted after contrast injection of...
corrosion casts (Fig. 3E, 3F) and MRV (Fig. 5F; Fig. 6J). A rostral intercavernous sinus could not be detected in any specimen. The CS emptied via an emissary vein through the foramen orbitotundum (EOvF), connecting the CS to the extracranial ophthalmic plexus (OP) (Fig. 6I). Another anastomotic branch between CS and extracranial pterygoid plexus (PP) (AR-CS+PP), which was also found to run through the foramen orbitotundum before turning laterally to the PP, was observed in corrosion casts (data not shown) as well as in MRV (Fig. 5D; Fig. 6J; Fig. 7D). This anastomosis has not been reported previously. The emissary vein of the oval foramen (EVOvF) was connected to the PP as well (Fig. 3E, for MRV see Fig. 5F; Fig. 6J; Fig. 7C). The CS continued caudally as the paired VPS which proceeded in a caudo-ventral direction. Before reaching the jugular foramen, the sinus was found to connect with its fellow, the anastomotic ramus of the VPS (AR-VPS) (Fig. 3E, 3F). The small-calibre AR-VPS was situated within the occipital bone between the pontine and medullary impressions and only visible in corrosion casts after bone removal. The VPS tapered and partly emptied into the emissary vein of the jugular foramen. The paired VOS, representing the caudal intercavernous sinus, emptied into the dorsal sagittal sinus (DSS) (H), the ventral occipital sinus (VOS; K), the anterior condylar confluent (ACC; J), as well as the great cerebral vein (GCV; E, F) and the straight sinus (SS; F, G). Note the faint signal of the thalamostrate veins (T5V; C, D), the internal cerebral veins (ICV, D), the basilar cerebral vein (BCV), and the dorsal petrosal sinus (DPS; D, F, H). Two anastomotic rami could be seen in MRV strongly: the anastomotic ramus between cavernous sinus and pterygoid plexus (AR-CS+PP; D) with a highly signal intensity and the anastomotic ramus between BCV and CS (AR-BCV+CS; G) as a diminutive vessel. ACC: anterior condylar confluent, AR-BCV+CS: anastomatic ramus between basilar cerebral vein and cavernous sinus, AR-CS+PP: anastomatic ramus between cavernous sinus and pterygoid plexus, AR-VOS: anastomotic ramus between both ventral occipital sinus, BCV: basilar cerebral vein, BuV: buccal vein, CIS: caudal intercavernous sinus, DCV: dorsal cerebral vein, DPS: dorsal petrosal sinus, DSS: dorsal sagittal sinus, EVJFHC: emissary vein of jugular foramen and hypoglossal canal, EVOvF: emissary vein of the foramen orbitotundum, EVRF1: emissary vein of the retroarticular foramen, EVRF2: second emissary vein of retroarticular foramen, GCV: great cerebral vein, ICV: internal cerebral vein, OP: ophthalmic plexus, PTV: profunatal temporal vein, RV: rhinal vein, SS: straight sinus, STV: superficial temporal vein, TeS: temporal sinus, TrS: transverse sinus, TSV: thalamostrate vein, VOS: ventral occipital sinus, VPS: ventral petrosal sinus.

doi:10.1371/journal.pone.0092990.g005

Course of the Emissary Veins of the Temporal Sinus and Formation of the Anterior Condylar Confluent

On either side, the transverse sinus (TrS) split into a rostral temporal sinus (TeS) and a caudal sigmoid sinus (SinS), clearly visible in corrosion casts (Fig. 1A, 1B) and on MRV images (Fig. 5G–5J; Fig. 6C; Fig. 7E–7H). The TeS entered the temporal meatus in a rostro-ventral direction where it split into two distinct vessels which emerged as emissary veins from the retroarticular foramen. The first emissary vein ran through the main retroarticular foramen (EVRF1) and joined the maxillary vein (MV) near the confluence of the superficial temporal vein (STV) (Fig. 4B, 4C; for MRV see Fig. 6E, 6F; Fig. 7H). The prominent second emissary vein of the tributary retroarticular foramen (EVRF2) was found along the tributary canal inside the temporal fossa and joined the deep temporal vein (PTV) as seen in both corrosion casts (Fig. 4B, 4C) and MRV (Fig. 5F; Fig. 6E, Fig. 7H). The SinS passed the condylar canal (CC) and drained into the VOS (Fig. 6E). Thus, the SinS connected the dorsal with the ventral sinus system. The VOS emptied into the internal vertebral venous plexus and into the emissary vein of the hypoglossal canal which left the skull through the hypoglossal canal. At the extracranial opening, the emissary veins of the jugular foramen and of the hypoglossal canal merged into a conspicuous, plexus-like structure which was detectable in corrosion casts (Fig. 4B, 4D, 4E) and on MRV images (Fig. 5J; Fig. 6I, 6J; Fig. 7D–7G). This structure is described as the anterior condylar confluent (ACC) in humans. It was located between the occipital condyle and the paracondylar process of the occipital bone. The ACC was concealed by the paracondylar process (Fig. 4D) in the lateral view. The ACC emptied into the emissary vein of the jugular foramen and hypoglossal canal (EVJFHC). The latter received the anastomotic ramus of the vertebral vein (AR-VV) prior to continuing as the craniooccipital vein (COV) which finally connected to the external jugular vein (EJV, Fig. 4B, 4D–4E).

Detectability of Cerebral Venous Structures by the Techniques Applied

A synopsis of the visibility of individual vessels in corrosion casts and by means of MRV is summarized in table 2. In principle, corrosion casts provide a superior visibility, particularly of very small structures. CTV could, to some extent, be used to compensate for occasional lack of detectability on MRV imaging.

Discussion

The major aim of the present study was to provide a comprehensive analysis of the ovine intracranial venous system by a combined approach using vascular corrosion casts and non-invasive in vivo imaging techniques. Relevant findings including hitherto not described anatomical structures are summarized in Fig. S1.

Interspecies Comparison: Most Relevant Differences and Species Assessment

Table 3 provides a comprehensive overview on the cerebral venous angioarchitecture in sheep, humans, dogs, and rats. Significant differences in cerebral arterial blood supply exist between rodents and humans. For example, numerous interarterial anastomoses can prevent major cortical infarction after distal (cortical) middle cerebral artery (MCA) occlusion in most non-hypertensive rodent strains [4]. These anastomoses are almost completely missing in humans (and domestic mammals), and occlusion of the MCA usually has disastrous consequences. Hence, similar differences may be presumed for the venous system. The cerebral venous drainage in rats and mice as the predominant cerebral venous outflow tracks should be explored thoroughly in further studies.

Canines represent an important model species used in translational cerebrovascular and neurointerventional research, since the anatomy of the arterial blood supply to the brain is very

Ovine Cerebral Venous System: Comparative Anatomy
Importantly, dogs lack a rete mirabile, a plexiform arterial network arising from the maxillary artery and forming the internal carotid artery, which is common in artiodactyls. Canines are therefore a preferred species for experimental arterial intravascular procedures. Anatomical and physiological similarities of assessed venous structures in comparison to human anatomy were slightly lower in dogs (16 out of 30) as compared to sheep (19 out of 30). Almost half of the structures (13 out of 30) have not been described in the rat, indicating a significant lack of knowledge about the species. Hence, the present study indicates a close resemblance of the intracranial venous system between sheep and man. The following paragraphs discuss functional and anatomical differences in selected venous structures between large animals and humans in more detail.

Overview on venous structures as seen in corrosion casts (CC) and MRV with respect to visibility of vessels (in alphabetical order). Visibility was rated by a score system: (−) not detectable; (+) barely visible; (++) moderately visible; (+++) distinctly visible. For structure denomination, please consult the table S1.

doi:10.1371/journal.pone.0092990.t002
Table 3. Interspecies comparison of venous structures in sheep, human, dogs and rats.

| Structure                      | Sheep                                      | Human                                      | Dog                                         | Rat                                         | Comparison                  |
|--------------------------------|--------------------------------------------|--------------------------------------------|---------------------------------------------|---------------------------------------------|-----------------------------|
| **Morphology of the dorsal sagittal sinus** |                                            |                                            |                                             |                                             |                             |
| DCVs                           | DCVs drain hemisphere surfaces, enter DSS [17,27,33,40,41] | Superior cerebral veins drain hemisphere surfaces, enter superior sagittal sinus [18] | DCV drain hemisphere surfaces, enter DSS [19,20,27,42] | denominated as superficial cerebral veins, enter superior sagittal sinus [15,44] | sheep = human = dog = rat |
| DSS                            | DSS begins at crista galli, some fine VE drain into the DSS, terminates into TrS [17,27,33,40,41] | denominated as superior sagittal sinus, anterior part sometimes absent, two superior cerebral veins replaced the sinus and functionally equivalent, sinus terminates into TrS [18,23,29] | DSS begins with large rostral dorsal cerebral veins, similar to sheep [19,20,27,42] | denominated as superior sagittal sinus, similar to sheep [15,43,44] | sheep = human = dog = rat (except the origin) |
| LVLs                           | LVLs are lateral DCV expansions, connected to DSS, contain arachnoid granulations for cerebrospinal fluid drainage [41] | LVLs communicate with irregularly shaped venous spaces in the dura mater near the superior sagittal sinus (DSS equivalent) [22] | similar to sheep [20,27] | n.d. | sheep = human = dog ≠ (?) |
| **Deep cerebral venous system** |                                            |                                            |                                             |                                             |                             |
| CIV                            | brush-like, with numerous short branches, drains TSV [27] | brush-like, with numerous short branches, drains TSV [45] | similar to sheep, but denominated as 'thalamic vein' [19,20] | n.d. | sheep = human = dog ≠ (?) |
| GCV (Gal)                      | formed by IVC at 'confluens venosus caudalis' [17,27] | formed by IVC and basal veins of Rosenthal forming at 'confluens venosus posterior' [18,24,45,46] | formed by IVC [19,20,27,42] | joins the aggregation of sinuses [43,44] | sheep = human = dog = (?) |
| IVC                            | formed by TSV and VSP [17,27] | formed by TSV and anterior septal veins [18,24,45] | similar to sheep [19,20,27] | similar to sheep [44] | sheep = human = dog = rat |
| LV                             | formed by Cv, DMBCV and RVCV and drained into the GCV | the lateral vein of lateral ventricle drain in the IVC, is denominated as 'lateral vein of lateral ventricle' [49] | n.d. | n.d. | sheep ≠ human ≠ (?) dog ≠ (?) |
| SS                             | formed by GCV (ventrally), and VCC (dorsally); drains into confluence of sinus or TrS [17,27,41] | receives inferior sagittal sinus, the great vein of Galen, and superior cerebellar veins; drains confluence of sinus or TrS [18,24,29] | similar to sheep [19,20,27,42] | similar to sheep [15,43,44] | sheep = human = dog = rat |
| TSP                            | receives venous drainage from VCN, VSP, and ChV [17] | receives venous drainage from VCN (anterior and transverse), anterior septal vein, and ChV, denominated as 'terminal vein' [18,45] | similar to sheep [19,20] | n.d. | sheep = human = dog ≠ (?) |
| VCC                            | collects blood regions of ethmoid and rostral cranial fossa, and chiasmatic sulcus, drains into the SS [27,41] | receives inflow from fala cerebri, upper surface of the corpus callosum, and medial surfaces of the hemispheres, denominated as 'inferior sagittal sinus' [18,29,45] | similar to sheep [19,20,27] | similar to sheep, but denominated as 'inferior sagittal sinus' [43,44] | sheep = human ≠ dog = rat |
| VCN                            | drains into TSV from rostrally and laterally | anterior and transverse caudate veins, drain into TSV [49] | n.d. | n.d. | sheep = human ≠ (?) rat |
Table 3. Cont.

| structure | sheep | human | dog | rat | comparison |
|-----------|-------|-------|-----|-----|------------|
| **VSP** connects with TSV, forming ICV on ‘confluens venosus rostralis’ | denominated as ‘anterior septal vein’ or ‘septal vein’ [18,45] | ‘choroidal vein’ is functionally and anatomically equivalent [20] | n.d. | sheep = human = dog ≠ (?) rat |
| **Ventral cerebral veins** | | | | | |
| **BCV** formed by RCVs and MCVs, Anastomosis to CS, enters DPS [17] | formed by anterior and deep middle cerebral, and inferior striate veins, terminates into ICV, SS or superior petrosal sinus, denominated as ‘basal vein of Rosenthal’ [18,24,45,46] | originates from several smaller veins, enters DPS | basal and rostral rhinal veins drain into the CS [15,43,44] | sheep = dog ≠ human ≠ rat |
| **DPS** forms main outflow track from the ventral cerebral veins, joins the ipsilateral TrS [17,27,33,41] | denominated as superior petrosal sinus, receives blood from the CS, from cerebellar and inferior cerebral veins [29] | similar to sheep [19,27] | drains into the TrS [15,44] | sheep = dog (?) rat ≠ human |
| **MCV** merges with RCV to form BCV, parallels MCA [17] | Deep middle cerebral veins form basal vein of Rosenthal with anterior cerebral and inferior striate veins [18,46] | similar to sheep, denominated as ‘deep middle cerebral vein’ [20] | n.d. | sheep = human = dog ≠ (?) rat |
| **superficial MCV** n.d. | starts at lateral hemispheric surface, ends in CS, sphenoparietal sinus or pterygoid plexus; anastomoses with veins of Trolard and Labbé [18,24,29] | n.d. | n.d. | only described in human |
| **RCV** arises from fine branches in the rostral cranial fossa, projects caudally and merges with MCV, forming the BCV [17] | denominated as anterior cerebral veins, form basal vein of Rosenthal together with deep MCV [18,24,29] | similar to sheep [20] | anterior/superficial cerebral veins arise from ventral capillaries and drain into the superior sagittal sinus; there is a posterior superficial cerebral vein receiving blood from dorsal capillary system [15] | sheep = human = dog ≠ rat |
| **RV** RV proceeds between impressions of the temporal and piniform lobes and receives input from the PLV before joining the DPS together with the BCV [17] | n.d. | not denominated anatomically, but potentially existing [20] | similar to sheep [48] | sheep = rat ≠ human ≠ dog |
| **Anastomoses of the ventral sinus system** | | | | | |
| **BP** n.d. | Basilar venous plexus communicates with inferior petrosal, cavernous, and marginal sinus [48] | n.d. | n.d. | sheep ≠ human ≠ rat ≠ dog |
| **CS** paired CS, next to occipital epidural rete mirabile [17,27,33,41] | paired CS, next to internal carotid artery [18,45,47] | paired CS, next to internal carotid artery [19,27,42] | paired CS, next to internal carotid artery [14,43,44] | sheep = human = dog = rat |
| **CS** are transversally connected | CS are transversally connected, complete ‘circular sinus’ [18,47] | n.d. [19,27,42] | n.d. | sheep = human ≠ (?) dog ≠ (?) rat |
| **RIS** n.d. | denominated as anterior intercavernous sinus, connects the two CS [18,47] | inconstant [19, 27, 42] | n.d. | sheep ≠ human ≠ dog ≠ (?) rat |
### Table 3. Cont.

| Structure | Sheep | Human | Dog | Rat | Comparison |
|-----------|-------|-------|-----|-----|------------|
| VOS       | caudal VPS continuation, receives input from SiS, drains into ACC and internal vertebral venous plexus. | n.d.; occipital sinus is functionally, but not anatomically equivalent [24] | similar to sheep [27] | n.d. | sheep = dog = human ≠ (?) rat |
| VPS       | caudal CS continuation, connects to ACC [17,27,33,41] | receives inflow from CS, internal auditory vein, and veins from the medulla oblongata, pons, and cerebellum, denominated as ‘inferior petrosal sinus’ [18,45] | similar to sheep [19,27,42] | n.d. | sheep = human = dog ≠ (?) rat |

**Course of the emissary veins of the temporal sinus and formation of the anterior condylar confluent**

| Structure | Sheep | Human | Dog | Rat | Comparison |
|-----------|-------|-------|-----|-----|------------|
| ACC       | formed by emissary vein of jugular foramen and emissary vein of hypoglossal canal, approximate size 10 to 12 mm x 7 mm, drains into the EVJFHC | formed by anterior and lateral condylar veins and branches of the internal jugular vein, the inferior petrosal sinus, the plexus of Rektorzik, and the prevertebral venous plexus, approximate size: 3 to 5 mm x 2 mm. [38,39] | n.d. | n.d. | sheep = dog ≠ (?) rat (location); sheep ≠ human = dog ≠ (?) rat (inflow) |
| SiS       | continued caudoventrally as caudal TrS branch, draining into VOS; connects dorsal and ventral sinus system. [17,27,33,41] | continuation of the TrS at occipitopetrosal junction; drains into internal jugular vein [18,24,29] | similar to sheep [19,27,42] | similar to sheep (origin) and human (end), respectively [48] | sheep = human = dog ≠ rat (origin); sheep ≠ human = rat ≠ dog (end) |
| TeS       | larger than SiS, merges with two emissary veins, drains into MV [27,33,41] and PTV | n.d. | similar to sheep [19,27,42] | functional equivalent: petrosquamosal sinus (but different anatomy) [14,43,44] | sheep = dog ≠ human ≠ rat |
| TrS       | DSS continuation, part of confluence of sinus [17, 27, 33, 41] | caudal continuation of superior sagittal sinus, part of the confluence of sinus [18,24,29] | similar to sheep [19,27,42] | similar to sheep [14,15,43,44] | sheep = human = dog = rat |

Other veins of Tro-lard, Labbé, n.d. Sylvius, and Rolando: present [18,24,29] | n.d. | n.d. | only described in human |

Morphology of the Dorsal Sagittal Sinus

The DSS is the main drainage system of the dorsal sinus system. In Merino sheep, it starts with the fusion of two to three dorsal rostral cerebral veins and collects blood from the DCV and from diploic veins [17]. This is similar to the situation in other domestic ruminants [17] and in humans, where the superior cerebral veins deliver blood to the superior sagittal sinus [18]. Variants have been described for dogs [19]. In canines, anastomoses between the rostral branches of the dorsal cerebral veins with branches of the RV have been reported [20], but no such variations were seen in our study. Moreover, some fine branches of ethmoidal veins delivered blood from the region of the crista galli to the DSS in our specimens. LVs of the DSS have been described in humans [21,22], monkeys [23], and dogs [20]. In humans, the LVs collect blood predominantly from the meningeal veins, but not from the cortical veins [24]. In contrast, the LVL were found to connect the DCG with the DSS in Merino sheep. Several types of chordae Willisii have been distinguished by using standard anatomical methods [21,25]. Our results corroborated these findings, with chordae displaying a trabecular, longitudinal or valve-like shape in sheep. Chordae Willisii in the median plane may functionally form a septum with trabecular and valve-like formations as seen in MRV. The latter are considered to prevent reverse blood flows and are also the most frequent type seen in humans [25]. In animals, the confluence of sinuses comprises the DSS, SS and TrS, whereas it encompasses the superior sagittal sinus, straight sinus, occipital sinus and transverse sinus in humans [26].

Deep Cerebral Venous System

In humans, the SS is connected either with the confluence of sinuses or, more commonly, with the left TrS [24]. The SS connects with the confluence of sinuses in Merino sheep, which is congruent with previous findings [27]. The VCG was very prominent in ovine corrosion casts, but less prominent in MRV and CTG, and may easily be confused with the human inferior sagittal sinus. The LVs, previously undescribed for sheep, joined the great cerebral vein. This is in contrast to the human anatomy, where LVs drain into ICVs. Ovine LVs receive inflow from three tributaries, which directly drain into the GCV in canines [20], omitting ICVs. The human equivalent of the ‘confluens venosus posterior’ is the ‘confluens venosus caudalis’. The ‘confluens venosus posterior’ in humans is formed of the GCV of Galen, as a merge of the internal cerebral veins and basal veins of Rosenthal [18]. In contrast, only the ICVs participate in the formation of the GCV in sheep. This formation has not been described in animals so far and, with respect to the human situation, may be denominated as ‘confluens venosus caudalis’. Another formation,
Figure 7. Sagittal MRV slices through the head of a sheep after intravenous injection of Gadolinium (Dotarem). (A) Dorsal view of the ovine brain. Lines delineate the levels of sagittal MRV slices, letters correspond to the letters in sagittal MRV images; B–H, MRV, sagittal sections. The sagittal sections provided a detailed depiction of all intracranial sinuses and veins, also the deep and ventral cerebral veins and particularly the confluence of sinus (B). Interestingly, the vein of corpus callosum (VCC) could not be detected in MRV. The thalamostriate vein (TSV; B, arrowheads) showed a cornu-like course and drained into the conspicuous internal cerebral vein (ICV; B). The weakly filled basilar cerebral vein (BCV; C, D, E, arrowheads) could easily be identified over a longer distances. BCVs and rhinal veins (RVs) drained through the dorsal petrosal sinus (DPS; D, E, F) into the transverse sinus (TrS; E, F, G). The TrS split into the temporal sinus (TeS) and the sigmoid sinus (SiS; F–H). Note the clear illustration of the TrS, TeS, SiS and the anterior condylar confluent (ACC; D–G). The ACC offered a large extent in these sagittal sections (D, arrowheads). The first (EVRF-1) and the second (EVRF-2; H, arrowhead) emissary vein of retroarticular foramen of sinus could be clearly identified. (EVRF-1) Dorsal view which allows the detection of vessels with relatively slow blood flow.

**Ventral Cerebral Veins**

The ventral cerebral veins are a group of veins which drain the rhinencephalon and enter the DPS, whereas the BCV is situated in the immediate vicinity of the arterial circle of Willis. This also applies to the RCV and MCV, which accompany the rostral and middle cerebral artery [17]. Several anastomoses to the more dorsal sinus system were noted in dogs [20]. In sheep, we found a correspondence to the RCV and the MCV. The basal vein in dogs continues on the lateral side of the cerebral peduncle and splits into dorsomedial and dorsolateral basal veins as described by Armstrong and Horowitz [20]. These authors also reported anastomoses between the dorsomedial basal vein and the GCV as well as between the basal vein and the cavernous sinus.

The first anastomosis could not be detected in our specimens. However, we found an anastomosis between the BCV and the CS. The basal vein in humans also commences at the anterior perforate substance by merging of the anterior cerebral, middle cerebral and striate veins [31]. The basal vein of each side takes its course around the midbrain and connects to the ICV or GCV [32]. The RV is the major vein of the ventral cerebral system and drains the caudo-ventral part of the hemisphere. The vein is rarely mentioned in the veterinary anatomy and has not been described in humans. BCV and RV connected with the DPS as opposed to the situation in humans, in which the basal vein empties into the ICV or GCV.

**Anastomoses of the Ventral Sinus System**

The CS starts at the foramen orbitorotundum in sheep [33], but at the orbital fissure in dogs [34]. It ends near the CIS. In humans, the CS extends from the superior orbital fissure to the top of the petrous pyramid [18]. The rostral intercavernous sinus is usually absent in sheep [27]. We could not detect a rostral intercavernous sinus, neither in corrosion casts nor in vivo by contrast-enhanced MRV or CTV, but found a prominent CIS in all specimens. In contrast to humans [18], however, no evidence of a completely ‘circular sinus’ was found in sheep. The rostral epidural rete mirabile is situated in close vicinity to the dura mater and invaginated into the CS [35,36]. The physiological function of this formation is thought to be the chilling of arterial blood supply to the brain. The absence of a rostral intercavernous sinus results in a horseshoe-shaped conformation of the ventral sinus system in dogs and sheep [27]. However, our data provide the first evidence for a strong anastomosis between the CS and PP, unveiling an additional outflow path from the CS. In our study, no evidence of a basilar sinus was found and the connection with the ventral internal vertebral plexus was established through the VOS.
Course of the Emissary Veins of the Temporal Sinus and Formation of the Anterior Condylar Confluent

In numerous species, the TrS divides into the TeS and the SiS on either side, with the intraosseous course of the TeS and the SiS only be visualized in MRV. The TeS connects with the MV via the emissary vein of the retroarticular foramen in sheep [37] and other species. The present work documents two possible venous routes in Merino sheep. The first is an emissary drainage from the TeS to the MV through the main retroarticular foramen, similar to the situation reported in dogs. The second is a strong vein connecting the TeS with the PTV through the tributary canal [17]. An anastomosis between the TeS and the OP, described by König [17], was neither seen in corrosion casts nor in MRV nor CTV. The second emissary pattern may be limited to ruminants (and horses) featuring a tributary canal of the temporal meatus of the TeS which is not observed in other species. Another novel finding in our study was a conspicuous, plexiform structure located extracranially near the openings of the jugular foramen and hypoglossal canal. To date, this venous confluent has only been reported in humans as the ‘anterior condylar confluent’ (ACC) [38,39]. It constitutes a vascular crossroad between the intracranial venous sinuses of the cranial canal fossa and the cranial cervical outflow tracks. The size of the human ACC ranges from 2 to 5 mm in a longitudinal direction and amounts to approximately 2 mm in its ventro-dorsal extension as seen in MRV.

Anatomical Implications for Translational Cerebrovascular Research

The anatomical similarity between sheep and humans might provide a solid basis for translational research on cerebrovascular diseases of the brain using ovine models. Notwithstanding, some fundamental differences to the human anatomy and hemodynamic physiology need to be considered carefully. For example, encephalic drainage preferentially occurs through vertebral, but not jugular veins in a physiological prone/upright position in both sheep and man [39]. In most quadrupeds including sheep, the longitudinal axes of skull and spine as well as those of major veins in this area meet at an obtuse angle. This is in contrast to humans where the longitudinal axes of skull and spine and major veins meet at a right angle. When lying in a supine position, main venous outflow shifts to the anterior, jugular tracks. This is a physiological situation in humans and, due to the right angle in which the venous vessels meet, does not cause any drainage problems. However, when animals are placed in a non-physiological supine position (e.g. for surgery or imaging procedures in large bore clinical scanners) and/or the head is fixed in a reclined position, both jugular and vertebral veins may become stretched and kinked, severely reducing the venous drainage capacity. This may lead to a significant backlog of venous blood and a concomitant increase of the intracranial pressure, severely damaging the brain over time.

Conclusions

Our study revealed novel aspects of the venous angioarchitecture of ovine intracranial venous sinuses and veins by means of ex vivo vascular corrosion casts, MRV and CTV. The detailed anatomical information obtained approves the notion of sheep as a relevant model species for translational research focussed on the cerebrovascular system. It also provides important implications for animal handling during such studies. An interspecies comparison between sheep, dogs and rats suggests that the cerebral venous angioarchitecture in large animals is better comparable with the human anatomy although substantial differences remain.

Supporting Information

Figure S1 Overview of the venous angioarchitecture of the sheep. This schematic representation summarizes the intracranial sinuses and veins including their interconnections and the connections with the extracranial venous system as shown in the figures. The marked veins in the red boxes have been described for the first time in the sheep. Uppercase numbers refer to references in the main document.

Table S1 Abbrevations of the described sinuses and veins according to the Nomina Anatomica Veterinaria, the Nomina Anatomica and the Terminologia Anatomica.

Acknowledgments

The authors thank Martina Fersterra and Uwe Lippmann (Institute of Anatomy, Histology and Embryology of the Faculty of Veterinary Medicine Leipzig), as well as Felix Schonlebe and Christian Georgieff for their excellent technical assistance during corrosion casts preparations. Moreover, the expert support during MRV and CTV imaging procedures provided by Anjize Dreyer, Teresa von Geymmüller and Violisa Zeissig (Fraunhofer Institute for Cell Therapy and Immunology, Leipzig) is gratefully acknowledged.
