Abstract We study residue formulas for push-forward in the equivariant K-theory of homogeneous spaces. For the classical Grassmannian, the residue formula can be obtained from the cohomological formula by a substitution. We also give another proof using symplectic reduction and the method involving the localization theorem of Jeffrey–Kirwan. We review formulas for other classical groups, and we derive them from the formulas for the classical Grassmannian. Next, we consider the homogeneous spaces for the exceptional group $G_2$. One of them, $G_2/P_2$ corresponding to the shorter root, embeds in the Grassmannian $Gr(2,7)$. We find its fundamental class in the equivariant K-theory $K^T(Gr(2,7))$. This allows to derive a residue formula for the push-forward. It has significantly different character compared to the classical groups case. The factor involving the fundamental class of $G_2/P_2$ depends on the equivariant variables. To perform computations more efficiently, we apply the basis of K-theory consisting of Grothendieck polynomials. The residue formula for push-forward remains valid for the homogeneous space $G_2/B$ as well.

1 Introduction

Suppose an algebraic torus $T = (\mathbb{C}^*)^r$ acts on a complex variety $X$ which is smooth and complete. Let $E$ be an equivariant complex vector bundle over $X$. Then, $E$ defines an element of the equivariant K-theory of $X$. In our setting, there is no difference whether one considers the algebraic K-theory or the topological one. We study the push-forward $p_!$ of the class of $E$ to the equivariant K-theory of a point (for the basics of equivariant K-theory see e.g. [12])

$$K^T(pt) \simeq R(T) \simeq \mathbb{Z}[t_1, t_2^{-1}, \ldots, t_r^{-1}].$$

Suppose that the fixed point set $X^T$ is finite. The localization formula allows to compute the push-forward using calculus of rational functions:

$$p_!(E) = \sum_{x \in X^T} \frac{E_x}{\prod_{i=1}^d \left( 1 - \frac{1}{L_i(x)} \right)}.$$ (1)

Here, the $T_x X = \bigoplus_{i=1}^d L_i(x)$ is the decomposition of the tangent space into a sum of one-dimensional representations. Identifying the representation ring $R(T)$ with Laurent polynomials, one obtains a sum whose summands are rational functions in $t_i$. After simplification, the result is a Laurent polynomial in $t_i$.

Formula (1) is a K-theoretic version of the cohomological Atiyah–Bott–Berline–Vergne localization formula [6,10]. It has appeared in the literature much earlier, see e.g. [5], [20, §4.7], [13, Cor. 6.12], [8]. This formula is also called “Holomorphic Lefschetz Theorem” in [7, (4.6)]. A relative version of the localization formula is given in [12, Th. 5.11.7]. In some of the quoted papers, one considers the actions of finite groups, but the modification to a torus action is purely formal.

We study the case when $X$ is a homogeneous space with the maximal torus action. One of the examples is the Grassmannian $X = Gr(m, n)$ of the $m$-dimensional spaces in $\mathbb{C}^n$. Suppose that $E$ is a vector bundle associated with a representation of $GL_m(\mathbb{C})$. Let $f(z_1, \ldots, z_m)$ be the character of this representation. Then, the formula (1) takes the form

$$p_!(E) = \sum_{A \subset \{t_1, t_2, \ldots, t_n\}, |A| = m} \frac{f(A)}{\prod_{a \in A} \prod_{b \in A^o} \left( 1 - \frac{a}{b} \right)}.$$ (2)

where $A^o = \{t_1, t_2, \ldots, t_n\} \setminus A$ and $f(A) = f(t_1, t_2, \ldots, t_m)$ for a subset $A = \{t_{i_1}, t_{i_2}, \ldots, t_{i_m}\}$ of the basic characters. (In Sect. 2, we introduce notation which allows to write this formula in a compact manner.)

Suppose $X$ is a space obtained by the symplectic reduction construction. This is the case for the Grassmannian, since

$$Gr(m, n) = \text{Hom}(\mathbb{C}^m, \mathbb{C}^n) \sslash U(m).$$

Equivalently, $Gr(m, n)$ is a GIT quotient $\text{Hom}(\mathbb{C}^m, \mathbb{C}^n) \sslash GL_m(\mathbb{C})$. Precisely, the Grassmannian is the geometric quotient of the open set consisting of the injective
maps $\mathbb{C}^m \to \mathbb{C}^n$. Then, the push-forward in equivariant K-theory can be expressed by a residue, just as in the case of cohomology. A generalization of the theory of Jeffrey–Kirwan [16] or Guillemin–Kalkman [14] applied to the homogeneous spaces leads to explicit residue formulas for the push-forward in equivariant cohomology. Such formulas for complete flag varieties first appeared in [9]. They were generalized to Grassmannians for the classical groups in [24]. A conceptual proof based on the Jeffrey–Kirwan theory is presented in [25]. Similar formulas can be obtained in equivariant K-theory. Formulas for Grassmannians and complete flag varieties appeared already in [1], see also [2]. In [1], the proof is omitted since it is stated that the proof is similar to [24] and that it just “requires more notation and paper”. Nevertheless, the proofs can be explained conceptually. The Jeffrey–Kirwan method can be applied for a class of generalized cohomology theories as shown in [18]. For the Grassmannian $Gr(m, n)$, the formula for the push-forward obtained via symplectic reduction is the following

$$p!(E) = \frac{1}{m!} \text{Res}_{Z=0, \infty} f(Z) \prod_{z \neq z'} \left(1 - \frac{z}{z'}\right) \prod_{t \in T} \prod_{z \in Z} \left(1 - \frac{t}{z}\right) \prod_{z \in Z} \frac{dz}{z},$$

(3)

where $Z = \{z_1, z_2, \ldots, z_m\}$ is an auxiliary set of variables. The operation $\text{Res}_{Z=0, \infty}$ is the iterated residue at 0 and $\infty$

$$(\text{Res}_{z_1=0} + \text{Res}_{z_1=\infty}) \circ (\text{Res}_{z_2=0} + \text{Res}_{z_2=\infty}) \circ \cdots \circ (\text{Res}_{z_m=0} + \text{Res}_{z_m=\infty}).$$

In our case, the order of taking the residues does not matter.

The formula for the classical Grassmannian allows one to write immediately the residue formulas for orthogonal and Lagrangian Grassmannians, using the embeddings $OG(2n) \subset Gr(n, 2n)$, $OG(2n+1) \subset Gr(n, 2n+1)$ and $LG(n) \subset Gr(n, 2n)$. The results are presented in Sect. 5. The general case requires embedding the homogeneous space in question into a flag variety and presenting the flag variety as a symplectic reduction. For classical groups, this is achieved in [26], where the cohomology formulas are derived. The case of K-theory is analogous and is discussed shortly in Sect. 4.2, and we give examples of resulting formulas in the final section. Our main goal is to present residue formulas for the exceptional group $G_2$. An embedding of $G_2/P_2$ (see §7 for the notation and [3] for the description of homogeneous spaces of $G_2$) into $Gr(2, 7) = \text{Hom}(\mathbb{C}^2, \mathbb{C}^7)/GL_2(\mathbb{C})$ is known. But the inverse image of $G_2/P_2$ in $\text{Hom}(\mathbb{C}^2, \mathbb{C}^7)$ is not a complete intersection, as is the case of classical groups. Moreover, its class in equivariant K-theory (also in equivariant cohomology) is significantly more complicated. The residue formula computing push-forward contains a factor which is given by Theorem 1. The case of the other homogeneous space $G_2/P_1$ is simpler, since this space embeds as a quadric in $\mathbb{P}^6$.

We would like to thank the anonymous Referees for many important comments which helped to improve the paper essentially.
2 Notation

Let $\mathbb{T}$ be a torus. Let $\mathbb{T}^\vee = \text{Hom}(\mathbb{T}, \mathbb{C}^*)$. The equivariant K-theory of a point is isomorphic to the group algebra

$$K^\mathbb{T}(pt) \simeq \mathbb{Z}[\mathbb{T}^\vee].$$

When $\mathbb{T} \simeq (\mathbb{C}^*)^n$, the group algebra $K^\mathbb{T}(pt)$ can be identified with Laurent polynomials $\mathbb{Z}[t_1^{\pm 1}, t_2^{\pm 1}, \ldots, t_n^{\pm 1}]$. The generator $t_i$ denotes the character (the representation) $\mathbb{T} \to \mathbb{C}^* = GL_1(\mathbb{C})$, which is the projection on the $i$th factor. We use the multiplicative notation for characters. For example, the character $t_2 t_4$ denotes the character $\mathbb{T} \to \mathbb{C}^*$, $(t_1, t_2, \ldots, t_n) \mapsto t_2 t_4$, while $t_2 + t_4$ stands for two-dimensional representation which decomposes into two one-dimensional representations having characters $t_2$ and $t_4$. The unit 1 is the class of the trivial representation of dimension 1.

2.1 Operations on sets of characters

For a set of characters $\{a_1, a_2, \ldots, a_k\} = A \subset \mathbb{T}^\vee$, let

- $A^{-1} = \{a^{-1} \mid a \in A\}$
- $\Lambda(A) = \{a_i a_j \mid 1 \leq i < j \leq k\}$
- $S(A) = \{a_i a_j \mid 1 \leq i \leq j \leq k\}$
- $R(A) = \{\frac{a}{b} \mid a, b \in A, a \neq b\}$
- $R^+(A) = \{a_i / a_j \mid i < j\}$.

For two sets of characters $A, B \subset \mathbb{T}^\vee$, let

- $A/B = \{\frac{a}{b} \mid a \in A, b \in B\}$

The definition of $R^+(A)$ depends on the ordering of $A$, while the remaining ones do not. Note that if $A$ is the set of coordinate characters $t_i$ for the maximal torus in $GL_n(\mathbb{C})$, then $R(A)$ is the set of roots and $R^+(A)$ is the set of positive roots.

2.2 Meromorphic functions associated with sets of characters

For a set of characters $A \subset \mathbb{T}^\vee$, let

- $[A] = \prod_{a \in A} (1 - \frac{1}{a}) \in K^\mathbb{T}(pt)$
- $d\log(A) = \prod_{a \in A} \frac{da}{a}$

These expressions are understood as meromorphic functions or forms on the product of $\mathbb{P}^1$'s.
2.3 Notation for multi-variable residue

For a meromorphic form \( f(z)dz \) on \( \mathbb{P}^1 \), let

\[
\text{Res}_{z=0,\infty} f \, dz = \text{Res}_{z=0} f \, dz + \text{Res}_{z=\infty} f \, dz.
\]

For a meromorphic form \( f(z_1, z_2, \ldots, z_n)dz_1dz_2 \ldots dz_n \), possibly depending on additional parameters, the following operator

\[
\text{Res}_{z_1=0,\infty} \circ \text{Res}_{z_2=0,\infty} \circ \cdots \circ \text{Res}_{z_n=0,\infty}
\]

will be denoted by \( \text{Res}_{Z=0,\infty} \).

3 The standard Grassmannian

Denote by \( Gr(m, n) \) the Grassmannian of \( m \)-subspaces in \( \mathbb{C}^n \). Let \( E \) be a vector bundle over the Grassmannian \( Gr(m, n) \) which is associated with a representation of \( GL_m(\mathbb{C}) \). Let \( f \in K^T(\text{pt}) \) be the associated character. It is a symmetric function \( f(A) = f(t_1, t_2, \ldots, t_m) \) in the coordinate characters of \( T = (\mathbb{C}^*)^m \). Let

- \( T = \{t_1, t_2, \ldots, t_n\} \),
- \( Z = \{z_1, z_2, \ldots, z_m\} \),
- \( A^o = T \setminus A \) for \( A \subset T \).

Let \( p : Gr(m, n) \to \text{pt} \) and let \( p_! : K^T(Gr(m, n)) \to K^T(\text{pt}) \) be the push-forward in the equivariant K-theory. In the introduction, we have described a residue formula for the push-forward in K-theory of the Grassmannian. In the notation introduced in §2 the push-forward for the classical Grassmannian can be expressed as

\[
p_!(E) = \sum_{A \subset T, \ |A| = m} \frac{f(A)}{[A^o/A]} = \frac{1}{m!} \text{Res}_{Z=0,\infty} \frac{f(Z) \cdot [R(Z)] \cdot d\log(Z)}{[T/Z]}.
\]

The expression above is nothing but the formulas (2) and (3) written in our notation. Another (more compact) formula is given by:

\[
p_!(E) = \text{Res}_{Z=0,\infty} \frac{f(Z) \cdot [R^+(Z)] \cdot d\log(Z)}{[T/Z]}.
\]

Here, there is no factor \( \frac{1}{m!} \), and the numerators are simpler: one can take only positive roots \( R^+(Z) \), without altering the result. A proof of this formula is sketched in [1, Prop 5.3].
4 Proof of residue formulas

The formula (4) can be deduced from the cohomological push-forward formula (see [22], Chapter 4. or [24], Corollary 3.2) or can be proved directly using symplectic reduction as in [25, 26].

4.1 Reduction to the cohomological formula

For a polynomial $g$ in $\mathbb{Z}$, one has

$$
\sum_{A \subset T, \sum_{t \in A} t^m} \frac{g(A)}{\prod_{x \in A} (t-x)} = \frac{1}{m!} \text{Res}_{Z=0} \prod_{z \in \mathbb{Z}} z^m \prod_{t \in T} (t-z) \prod_{z \in \mathbb{Z}} z^m \prod_{t \in T} (t-z).
$$

The same formula is valid for Laurent polynomials, provided that we take into account the residues at zero. Let $g(Z) = f(Z)/\prod_{z \in \mathbb{Z}} z^m$. Then

$$
\sum_{A \subset T, \sum_{t \in A} t^m} \frac{f(A)}{\prod_{x \in A} (t-x)} = \frac{1}{m!} \text{Res}_{Z=0, \infty} \prod_{z \in \mathbb{Z}} z^m \prod_{t \in T} (t-z) \prod_{z \in \mathbb{Z}} z^m \prod_{t \in T} (t-z).
$$

The left-hand side is equal to

$$
\sum_{A \subset T, \sum_{t \in A} t^m} \frac{f(A)}{\prod_{x \in A} (t-x)} \prod_{t \in T} t^m \prod_{z \in \mathbb{Z}} \left(1 - \frac{x}{t}\right),
$$

while the right-hand side equals

$$
\frac{1}{m!} \text{Res}_{Z=0, \infty} \prod_{z \in \mathbb{Z}} z^m \prod_{t \in T} (t-z) \prod_{z \in \mathbb{Z}} z^m \prod_{t \in T} (t-z) = \frac{1}{m!} \text{Res}_{Z=0, \infty} \prod_{z \in \mathbb{Z}} z^m \prod_{t \in T} (1 - \frac{z}{t})
$$

Multiplying both sides by $\prod_{t \in T} t^m$, we obtain the formula (4), that is

$$
\sum_{A \subset T, \sum_{t \in A} t^m} \frac{f(A)}{\prod_{x \in A} (t-x)} \prod_{t \in T} t^m \prod_{z \in \mathbb{Z}} \left(1 - \frac{x}{t}\right) = \frac{1}{m!} \text{Res}_{Z=0, \infty} \prod_{z \in \mathbb{Z}} z^m \prod_{t \in T} (1 - \frac{z}{t}).
$$

Note that if $f$ is homogeneous of degree at least $m$ in each variable, then the residue at 0 vanishes.

4.2 Proof via symplectic reduction

The proof is based on the fact that $Gr(m, n)$ is a symplectic reduction of $V = \text{Hom}(\mathbb{C}^m, \mathbb{C}^n)$ and the following two propositions:
**Proposition 1** For a representation

\[ [E] \in K^{GL_m(\mathbb{C})\times T}(V) \cong K^{GL_m(\mathbb{C})\times T}(pt), \]

there is an equality

\[ p!(EV/\!/GL_m(\mathbb{C})) = q!(\varpi EV/\!/T_m) \in K^T(pt). \]

Here, \( T_m \) is a maximal torus in \( GL_m(\mathbb{C}) \), \( q : V/\!/T_m \rightarrow pt \) and

\[ \varpi = \prod_{\alpha \in \text{roots of } GL_m(\mathbb{C})} (1 - \alpha). \]

The factor \( \varpi \) is equal to \([R(Z)]\) according to our notation, provided that \( z_i \)'s are the standard coordinates of the diagonal maximal torus in \( GL_m(\mathbb{C}) \). The symplectic reduction \( V/\!/T_m \) is a product of projective spaces.

**Proposition 2** For a class \( E \in K^{C^r\times T(\mathbb{C}^n)} \cong K^{C^r\times T}(pt) \) given by the character \( f(z, t_1, t_2, \ldots, t_n) \) we have

\[ q!(E_{\mathbb{P}^{n-1}}) = \text{Res}_{z=0, \infty} \left( \frac{f(z, t_1, t_2, \ldots, t_n)}{z \prod_{i=1}^n (1 - \frac{z}{t_i})} dz \right) \]

Proposition 1 is a K-theoretic version of the Jeffrey–Kirwan Theorem ([16]). For the proof, see [15], Theorem 5.3.

**Proof of Proposition 2.** The map

\[ f(z, t_1, t_2, \ldots, t_n) \mapsto \text{Res}_{z=0, \infty} \left( \frac{f(z, t_1, t_2, \ldots, t_n)}{z \prod_{i=1}^n (1 - \frac{z}{t_i})} dz \right) \]

is linear with respect to the ring \( \mathbb{Z}[t_1^{\pm 1}, t_2^{\pm 1}, \ldots, t^n_{\pm 1}] \), hence it is enough to examine the formula of the proposition for \( f(z, t_1, t_2, \ldots, t_n) = z^k \). Let us first consider the case \( k = -\ell \leq 0 \). Then, the form

\[ g(z) = \frac{f(z, t_1, t_2, \ldots, t_n)}{z \prod_{i=1}^n (1 - \frac{z}{t_i})} dz = \frac{dz}{z^{\ell+1} \prod_{i=1}^n (1 - \frac{z^{t_i}}{t_i})} \]

has no pole at infinity and the residue at 0 is equal to the coefficient of \( z^{\ell} \) in the expansion

\[ \frac{1}{\prod_{i=1}^n (1 - \frac{z}{t_i})} = \prod_{i=1}^n \sum_{j=0}^\infty \frac{z^j}{t_i^j}. \]
This coefficient is equal to the $\ell$–th complete symmetric function in the inverses of variables $t_i$

$$\sum_{|\lambda|=\ell} t^{-\lambda}.$$ 

This is the character of the representation $\text{Sym}^\ell(\mathbb{C}^n)^* = q! (O(\ell))$, that is exactly what we had to show.

For $f(z^k, k \in [1, n-1]$, the function $g(z)$ has no pole at 0 nor at infinity. For $k \geq n$, we only have a residue at infinity. Substituting $z$ by $w^{-1}$ and applying the transformation

$$\frac{z^k}{z} \prod_{i=1}^{n} (1 - \frac{z}{t_i}) \, dz = \frac{-1}{w^{k-1}} \prod_{i=1}^{n} (1 - \frac{1}{w t_i}) \, dw = \frac{(-1)^{n-1}}{w^{k+n-1}} \prod_{i=1}^{n} (1 - w t_i) \, dw$$

we obtain the result by Serre duality.

5 The residue formulas derived from Section 3

Below, we consider Lagrangian and orthogonal Grassmannians which are invariant with respect to smaller tori. In all the considered cases, the fixed point set in the big Grassmannian with respect to the small torus is equal to the fixed point set with respect to the full torus action. Therefore, we can apply the residue formula and specialize it to the smaller torus. In all the cases, we apply the projection formula: for $\iota : G \hookrightarrow Gr(k, n)$, we have

$$(p|_G)_!(\iota^* E) = p!(\iota_! ([G] \cdot E)),$$

where $[G] = \iota_!(1)$ is the fundamental class of $G$ in the K-theory of the Grassmannian.

5.1 Lagrangian Grassmannian

Let $LG(n) \subset Gr(n, 2n)$ be the Lagrangian Grassmannian. Set

- $T = \{t_1, t_2, \ldots, t_n\}$,
- $T^\pm = T \cup T^{-1}$,
- $Z = \{z_1, z_2, \ldots, z_n\}$.

Let $p_L : LG(n) \to pt$. Then,

$$p_L_!(E) = \sum_{A \subset T} \frac{f(A \cup A^{\alpha-1})}{[S(A^{-1} \cup A^\alpha)]} = \frac{1}{n!} \text{Res}_{Z=0, \infty} \frac{f(Z) \cdot [\Lambda(Z^{-1})] \cdot [R(Z)] \cdot d\log(Z)}{[T^{\pm1}/Z]}.$$ 

The first equality follows from the Atiyah–Bott–Berline–Vergne formula for $LG(n)$. The fixed points are indexed by subsets of $T$ and the tangent space at the fixed subspace
$W_A$ corresponding to the subset $A$ is canonically identified with $\text{Sym}^2(W_A^*)$. The second equality is obtained by applying the formula (4) for the classical Grassmannian $Gr(n, 2n)$ and restricting the action to the smaller torus $(t_1, \ldots, t_n, t_n^{-1}, \ldots, t_1^{-1}) \mapsto (t_1, \ldots, t_{2n})$. The factor $\Lambda(Z)$ corresponds to the fundamental class of $LG(n)$, as follows. The set of Lagrangian maps $C^n \rightarrow \mathbb{C}^{2n}$ is a complete intersection in $\text{Hom}(C^n, C^{2n})$, described by the $n(n+1)/2$ independent equations of the form $\omega(v_i, v_j) = 0$ for $1 \leq i < j \leq n$. Here, $\omega$ is the symplectic form and $v_i$ are the column vectors of the matrix corresponding to an element of $\text{Hom}(C^n, C^{2n})$. The set of weights of the equations is equal to $S(Z^{-1})$, where $z_i$ are characters associated to the source.

5.2 Orthogonal Grassmannian, even case

Let $OG(2n) \subset Gr(n, 2n)$ be the isotropic Grassmannian (two components). As before, set

- $T = \{t_1, t_2, \ldots, t_n\}$,
- $T^\pm = T \cup T^{-1}$,
- $Z = \{z_1, z_2, \ldots, z_n\}$.

Let $p_O : OG(2n) \rightarrow pt$. Then,

$$p_O! (E) = \sum_{A \subset T} \frac{f(A \cup A^o - 1)}{[\Lambda(A^{-1} \cup A^o)]} = \frac{1}{n!} \text{Res}_{Z=0,\infty} \frac{f(Z) \cdot [S(Z^{-1})] \cdot [R(Z)] \cdot d\log(Z)}{[T^\pm / Z]}.$$ 

As in the case of the Lagrangian Grassmannian, the first equality is simply the Atiyah–Bott–Berline–Vergne formula. The fixed points are indexed by subsets of $T$, and the tangent space at the subspace $W_A$ corresponding to a subset $A$ is canonically identified with $\Lambda^2(W_A^*)$. Note that the set of isotropic maps $\mathbb{C}^n \rightarrow \mathbb{C}^{2n}$ is a complete intersection in $\text{Hom}(\mathbb{C}^n, \mathbb{C}^{2n})$, described by the $n(n+1)/2$ independent equations of the form $\Omega(v_i, v_j) = 0$ for $1 \leq i \leq j \leq n$. Here, $\Omega$ is a nondegenerate symmetric form and $v_i$ are the column vectors of the matrix corresponding to an element of $\text{Hom}(\mathbb{C}^n, \mathbb{C}^{2n})$. The set of weights of the equations is equal to $S(Z^{-1})$, where $z_i$ are characters associated to the source.

5.3 Orthogonal Grassmannian, odd case

Let $OG(2n+1) \subset Gr(n, 2n+1)$ be the isotropic Grassmannian. As before, set

- $T = \{t_1, t_2, \ldots, t_n\}$,
- $T^\sharp = T \cup T^{-1} \cup \{1\}$,
- $Z = \{z_1, z_2, \ldots, z_n\}$. 

$\odot$ Springer
Let $p_O : OG(2n + 1) \to pt$. Then
\[
p_O!(E) = \sum_{A \subset T, |A|} \frac{f(A \cup A^o)}{[\Lambda(A^{-1} \cup A^o)] \cdot [A^{-1} \cup A^o]}
\]
\[
= \frac{1}{n!} \text{Res}_{Z=0,\infty} \frac{f(Z) \cdot [S(Z^{-1})] \cdot [R(Z)] \cdot d\log(Z)}{[T^\pm/Z]}
\]

The set of isotropic maps $\mathbb{C}^n \to \mathbb{C}^{2n+1}$ is a complete intersection in $\text{Hom}(\mathbb{C}^n, \mathbb{C}^{2n+1})$, described by the same equations as for the even-dimensional case. The set of weights of the equations is therefore equal to $S(Z^{-1})$, where $z_i$ are characters associated with the source. Note that here we have a factor $[z_i^{-2}] = 1 - z_i^2$ in the numerator and $[z_i^{-1}] = 1 - z_i$ in the denominator. We simplify the whole expression and obtain
\[
p_O!(E) = \frac{1}{n!} \text{Res}_{Z=0,\infty} \frac{f(Z) \cdot [\Lambda(Z^{-1})] \cdot [-Z^{-1}] \cdot [R(Z)] \cdot d\log(Z)}{[T^\pm/Z]}
\]

6 Grassmannian of $\phi$-isotropic planes

Consider the root system of the exceptional group $G_2$, with simple roots $\alpha_1$ and $\alpha_2$.

Let $B$ be the Borel subgroup defined by the positive roots. The group $G_2$ has exactly two maximal parabolic subgroups containing $B$, corresponding to the two choices of simple roots. We denote by $P_i$ the parabolic subgroup in which the root $-\alpha_i$ is omitted. Anderson in [4] gave an interpretation of homogeneous spaces for $G_2$. Given a nondegenerate trilinear form $\phi : \Lambda^3 \mathbb{C}^7 \to \mathbb{C}$, a two-dimensional subspace $V$ is called $\phi$-isotropic if $\phi(x, y, z) = 0$ for all $x, y \in V, z \in \mathbb{C}^7$. The homogeneous
space $G_2/P_2$ parameterizes two-dimensional $\phi$-isotropic subspaces in $\mathbb{C}^7$, yielding an embedding of $G_2/P_2$ in the Grassmannian $Gr(2, 7)$. The embedding allows us to derive a residue formula for push-forward.

**Theorem 1** Suppose a bundle $E \to G_2/P_2$ is associated with a character $f(Z) = f(z_1, z_2)$. Then,

$$p_{G_2/P_2}(E) = \text{Res}_{Z=0,\infty} \frac{f(Z) \cdot \mathcal{U}(Z, T) \cdot [R^+(Z)] \cdot d\log(Z)}{[T^b/Z]} ,$$

where

$$T^b = \{ t_1, t_2, t_1^{-1} t_2^{-1}, 1, t_1^{-1} t_2, t_2^{-1}, t_1^{-1} \}$$

and

$$\mathcal{U}(Z, T) = z_1 z_2 (1 - z_1) (1 - z_2) (1 - z_1 z_2) (\mathcal{U}_z(Z) - \mathcal{U}_t(T)) ,$$

with

$$\mathcal{U}_z(Z) = z_1 + \frac{1}{z_1} + z_2 + \frac{1}{z_2} + z_1 z_2 + \frac{1}{z_1 z_2} - 6 ,$$

$$\mathcal{U}_t(T) = \mathcal{U}_z \left( \frac{1}{t_1}, \frac{1}{t_2} \right) = t_1 + \frac{1}{t_1} + t_2 + \frac{1}{t_2} + \frac{t_1}{t_2} + \frac{t_2}{t_1} - 6 .$$

We describe the embedding $G_2/P_2 \hookrightarrow Gr(2, 7)$ in detail and derive the residue formula in the next section. For more details of computations, see “Appendix”. Also there it is given a formula obtained directly from Atiyah-Bott–Berline-Vergne theorem. That is a sum of six rational functions, see the formula (8).

**7 Computation of the polynomial $\mathcal{U}(Z, T) = [G_2/P_2] \subset K^T (Gr(2, 7))$**

The exceptional Lie algebra $g_2$ is the fixed set of the triality automorphism of $\mathfrak{so}(8)$. The triality automorphism of the real form $\mathfrak{so}(4, 4)$ permutes the off-diagonal entries (up to a sign). The resulting embedding $g_2 \hookrightarrow \mathfrak{gl}_8$ computed in [19] is the following:

$$
\begin{pmatrix}
  t_1 & a_1 & a_6 & t_2 \\
  a_6 & t_2 & t_1 & a_1 \\
  a_8 & a_9 & t_1 - t_2 & a_1 \\
  a_{10} & a_8 & a_6 & 0 \\
  a_{10} & a_8 & a_6 & 0 \\
  a_{11} & a_{10} & 0 & a_6 \\
  a_{12} & 0 & -a_{10} & -a_8 \\
  0 & -a_{12} & -a_{11} & -a_{10} & a_8 & a_6 & t_1
\end{pmatrix}
$$

(5)
In this presentation of \( g_2 \subset \mathfrak{gl}_8 \), the 4th and the 5th coordinates are equal, hence \( g_2 \) annihilates the vector \((0, 0, 0, 1, -1, 0, 0, 0)\) and therefore preserves its orthogonal complement. Hence,

\[
g_2 \subset \mathfrak{gl}(\text{span}\{\varepsilon_1, \varepsilon_2, \varepsilon_3, \varepsilon_4 + \varepsilon_5, \varepsilon_6, \varepsilon_7, \varepsilon_8\}) \simeq \mathfrak{gl}_7.
\]

The parabolic group \( P_2 \) is equal to the intersection of \( G_2 \) with the standard block-upper-triangular matrices in \( GL_7(\mathbb{C}) \) preserving the first two coordinates. The weights of the tangent space \( T_{[1]} G_2 / P_2 \) are the following:

| Coordinate | \( a_8 \) | \( a_9 \) | \( a_{10} \) | \( a_{11} \) | \( a_{12} \) |
|------------|------------|------------|------------|------------|------------|
| Weight     | \(-t_2\)   | \(t_1 - 2t_2\) | \(-t_1\)   | \(t_2 - 2t_1\) | \(-t_1 - t_2\) |

Another description of the embedding is given in [3]. Given a two-dimensional space \( W \), one identifies \( \mathbb{C}^7 \) with \( W \oplus \text{End}^0(W) \oplus W^* \), where \( \text{End}^0(W) \) denotes the trace 0 endomorphisms of \( W \). The antisymmetric trilinear form \( \phi \) on \( \mathbb{C}^7 \) is induced by the map

\[
(\nu, F, f) \mapsto f(F(\nu))
\]

and \( W \) is isotopic with respect to this form. The tangent space to \([W]\) in \( G_2 / P_2 \) coincides, via this embedding, with

\[
(\text{Sym}^3 W^* \otimes \Lambda^2 W) \oplus \Lambda^2 W^* \hookrightarrow \text{Hom}(W, \text{End}^0(W) \oplus W^*).
\]

The weights of the action of the tangent space (in the multiplicative notation) are therefore \( \{t_1^{-2}t_2, t_1^{-1}, t_2^{-1}, t_1t_2^{-2}, t_1^{-1}t_2^{-1}\} \). This agrees with the embedding (5).

Since \( G_2 / P_2 \) embeds in the Grassmannian \( Gr(2, 7) \), the push-forwards in K-theory are related as follows. Let \( \mathbb{T} \) denote the maximal torus in \( G_2 \). The set of characters obtained from the embedding to \( GL_7(\mathbb{C}) \) described by (5) is equal to

\[
T^0 = \{t_1, t_2, t_1t_2^{-1}, 1, t_1^{-1}t_2, t_2^{-1}, t_1^{-1}\}.
\]

The torus \( \mathbb{T} \) acts on \( Gr(2, 7) \) leaving \( G_2 / P_2 \) invariant. Given a class \( a \in K^\mathbb{T}(Gr(2, 7)) \), let \( i^*a \) denote its restriction to \( K^\mathbb{T}(G_2 / P_2) \) via the embedding

\[
i : G_2 / P_2 \hookrightarrow Gr(2, 7).
\]

Then, \( p_{G_2!}(i^*a) = p_!(i([G_2 / P_2] \cdot a)) \), where

\[
p_! : K^\mathbb{T}(Gr(2, 7)) \to K^\mathbb{T}(pt) \quad \text{and} \quad p_{G_2!} : K^\mathbb{T}(G_2 / P_2) \to K^\mathbb{T}(pt)
\]
are the respective push-forwards. If the class \( t^a \) is represented by a bundle \( E \to G_2/P_2 \) associated with a character \( f(Z) = f(z_1, z_2) \), then by the residue formula (4) for \( Gr(2, 7) \) one gets

\[
p_{G_2}(E) = \text{Res}_{Z=0,\infty} \frac{f(Z) \cdot \mathcal{U}(Z, T) \cdot [R^+(Z)] \cdot \text{dlog}(Z)}{[T^\vee/Z]},
\]

where

\[ \mathcal{U}(Z, T) \in K^{GL(2) \times T}(pt) \subset \mathbb{Z}[z_1, z_1^{-1}, z_2, z_2^{-1}, t_1, t_1^{-1}, t_2, t_2^{-1}] \]

is a lift of the fundamental class \([G_2/P_2] \subset K^T(Gr(2, 7))\). The lift \( \mathcal{U}(Z, T) \) is not unique and might be quite complicated. It remains to find a convenient form of \( \mathcal{U}(Z, T) \). We have found a formula which seems to have a nice and remarkable shape.

We start with a warm-up presenting the computation of the cohomology class of \( G_2/P_2 \) in \( H^*(Gr(2, 7)) \). It is simpler than finding the class in K-theory, but essentially the method is the same. The computations presented in this section have been performed using Wolfram Mathematica, see “Appendix” and [23]. To find the cohomology class, we integrate the Schur classes \( S_{5}, S_{41} \) and \( S_{32} \) of the dual of the tautological bundle. These classes form a self-dual basis of \( H^{10}(Gr(2, 7)) \). We find (e.g. using Atiyah–Bott–Berline–Vergne integration formula) that

\[
\int_{G_2/P_2} S_{5}(\gamma^*) = 0, \quad \int_{G_2/P_2} S_{41}(\gamma^*) = 2, \quad \int_{G_2/P_2} S_{32}(\gamma^*) = 2.
\]

Therefore,

\[
[G_2/P_2] = 2S_{41}(\gamma^*) + 2S_{32}(\gamma^*) \in H^{10}(Gr(2, 7)). \tag{6}
\]

An analogous calculation can be performed in equivariant cohomology. The equivariant Schur classes \( S_{I} = S_{I}(\gamma^*) \), for \( I \) contained in the rectangle \( 5 \times 2 \), form a basis of \( H^*_T(Gr(2, 7)) \) as a free module over \( H^*_T(pt) \). We note that the Schur polynomials we use here are not the double Schur polynomials (representing equivariant classes of Schubert varieties), but we apply usual Schur polynomials to the equivariant bundle \( \gamma^* \). Then, except from the classes \( S_{41} \) and \( S_{32} \), we obtain nonzero result for

\[
\int_{G_2/P_2} S_{52}(\gamma^*) = 4(t_1^2 - t_1t_2 + t_2^2), \quad \int_{G_2/P_2} S_{43}(\gamma^*) = 2(t_1^2 - t_1t_2 + t_2^2),
\]

\[
\int_{G_2/P_2} S_{54}(\gamma^*) = 2(t_1^2 - t_1t_2 + t_2^2)^2.
\]

Inverting the intersection matrix, we obtain a coefficients in the equivariant Schur basis:

\[
[G_2/P_2] = 2S_{41} + 2S_{32} - 2(t_1^2 - t_1t_2 + t_2^2)S_{21} \in H^{10}_T(Gr(2, 7)).
\]
This shows that the equivariant fundamental class of $G_2/P_2$ has higher-order coefficients in the Schur basis. Such situation does not appear for the classical groups. In the terms of the Chern roots $x_1, x_2$ of the bundle $γ^*$, the fundamental class is equal to

$$2x_1x_2(x_1 + x_2)[(x_1^2 + x_1x_2 + x_2^2) - (t_1^2 - t_1t_2 + t_2^2)].$$

The same procedure leads to finding the class in K-theory. There is a small difference, which in fact is not a problem from the theoretical point of view: there is no grading in K-theory. One has to take into account all partitions contained in the $5 \times 2$ rectangle. We replace the Schur basis by the basis consisting of the Grothendieck classes of $γ^*$, i.e. the (stable) Grothendieck polynomials in the formal roots of $γ^*$ ([11,17]). Grothendieck classes represent the classes of the structure sheaves of Schubert varieties in nonequivariant K-theory. Our notation agrees with [11,21]. This basis has “skew-upper-triangular” intersection form, which means that

$$p_!(G_I(γ^*)G_J(γ^*)) = 0 \in K(pt) = \mathbb{Z} \text{ if } I \not\subset c(J).$$

Here, $c(J)$ denotes the complementary partition. The intersections of Schubert varieties are rational varieties; therefore, one has

$$p_!(G_I(γ^*)G_J(γ^*)) = 1 \text{ if } I \subset c(J).$$

We compute the push-forward of the (nonequivariant) Grothendieck classes $G_I(γ^*)$ for the map $G_2/P_2 \to pt$, e.g. applying the localization formula [13, Cor. 6.12]. We obtain the following list of results:

| Partition $I$ | [0] | [1] | [2] | [11] | [3] | [21] | [40] | [31] | [22] | [50] | [41] | [32] |
|---------------|-----|-----|-----|------|-----|------|------|------|------|------|------|------|
| $p_{G_2!}(SI(γ^*))$ | 1   | 1   | 1   | 1    | 1   | 2    | 1    | 1    | 0    | 2    | 2    |      |

The push-forwards for the partitions $I$ with $|I| > 5$ vanish since for those partitions $G_I$ is supported by a variety of the codimension $> 5 = \dim G_2/P_2$. Inverting the intersection matrix of $K(Gr(2, 7))$, we find that the nonequivariant class of $G_2/P_2$ in the K-theory is equal to

$$2G_{41} + 2G_{32} - G_{33} - 3G_{42} + G_{43}. \quad (7)$$

(We omit $γ^*$ in the notation.) This class can be written in the Grothendieck roots of the tautological bundle as

$$z_1z_2(1 - z_1)(1 - z_2)(1 - z_1z_2)\left(z_1 + \frac{1}{z_1} + z_2 + \frac{1}{z_2} + z_1z_2 + \frac{1}{z_1z_2} - 6\right).$$

In the same way, one computes the equivariant class. The equivariant Grothendieck classes of the bundle $γ^*$ form a basis of $K^T(G_2/P_2)$ as a module over $K^T(pt) = \mathbb{Z}[t_1, t_1^{-1}, t_2, t_2^{-1}]$. The resulting class is equal to

\[ \text{Springer} \]
where $z_i = c_1(u_i)$. The class $G_{a,b}(u_1 \oplus u_2)$ is a polynomial in the inverses of $u_i$'s, which is why we use Grothendieck roots of the dual bundle. For example,

\[
\begin{align*}
G_0(\gamma^*) &= 1 \\
G_1(\gamma^*) &= 1 - z_1 z_2 \\
G_2(\gamma^*) &= z_2 z_1^2 + z_2^2 z_1 - 3 z_2 z_1 + 1 \\
G_{11}(\gamma^*) &= (1 - z_1)(1 - z_2) \\
G_3(\gamma^*) &= -z_2 z_1^3 - z_2^2 z_1^2 + 4 z_2 z_1^2 - z_3 z_1 + 4 z_2^2 z_1 - 6 z_2 z_1 + 1 \\
G_{21}(\gamma^*) &= (1 - z_1)(1 - z_2)(1 - z_1 z_2) \\
G_4(\gamma^*) &= z_2 z_1^4 + z_2^2 z_1^3 - 5 z_2 z_1^3 + z_2 z_1^2 - 5 z_2^2 z_1^2 + 10 z_2 z_1^2 + z_2^4 z_1 - 5 z_2^3 z_1 + \\
&
+ 10 z_2 z_1^2 - 10 z_2 z_1 + 1 \\
G_{31}(\gamma^*) &= (1 - z_1)(1 - z_2) \left(z_2 z_1^2 + z_2^2 z_1 - 3 z_2 z_1 + 1\right) \\
G_{22}(\gamma^*) &= (1 - z_1)^2 (1 - z_2)^2
\end{align*}
\]

where $z_1$ and $z_2$ are Grothendieck roots of $\gamma$. The Chern character transports the Grothendieck classes to Schur classes modulo higher gradation:

\[
ch(G_I(\gamma)) = S_I(\gamma) + \sum_{J \supset I} a_J S_J(\gamma).
\]
For example of partitions appearing in (7):

\[
ch(G_{41}) = S_{41} - (S_{42} + 2S_{51}) + \left( \frac{1}{2}S_{43} + \frac{25}{12}S_{52} + \frac{13}{6}S_{61} \right) - \left( \frac{1}{6}S_{44} + \frac{13}{12}S_{53} + \frac{7}{3}S_{62} + \frac{5}{3}S_{71} \right) + \cdots,
\]

\[
ch(G_{32}) = S_{32} - \left( \frac{3}{2}S_{33} + \frac{3}{2}S_{42} \right) + \left( \frac{7}{3}S_{43} + \frac{5}{4}S_{52} \right) - \left( \frac{5}{4}S_{44} + 2S_{53} + \frac{3}{4}S_{62} \right) + \cdots
\]

for bundles of rank two. The Chern character allows to deduce the formulas in cohomology (6) from those in K-theory.

Remark 2 Formula for the class of \(G_{2}/P_{2}\) in K-theory is not unique since there are relations between the variables \(z_{1}, z_{2}, t_{1}\) and \(t_{2}\). When written in terms of Grothendieck classes of \(\gamma\) the formula becomes much more complicated.\(^{1}\) The difference appears because, unlike the equality for Schur classes, in general \(G_{I}(\gamma^{*}) \neq (-1)^{|I|}G_{I}(\gamma)\). In the case of cohomological fundamental class, there is no ambiguity. The classes \(S_{50}, S_{41}\) and \(S_{32}\) span both \(H^{10}(Gr(2, 7))\) and the space of polynomials in two variables of degree 5. Therefore, the presentation of \([G_{2}/P_{2}] \in H^{10}(Gr(2, 7))\) in terms of Chern roots of \(\gamma^{*}\) is unique.

8 More residue formulas

As an addendum, we list another two residue formulas which are available in the literature or just checked by us.

8.1 Standard Grassmannian, two sets of characters

Suppose a bundle \(E\) over \(Gr(m, n)\), associated with a representation of \(GL_{m}(\mathbb{C}) \times GL_{n-m}(\mathbb{C})\), is given. Let \(f(t_{1}, t_{2}, \ldots, t_{n})\) be its character. It is symmetric with respect to \(\Sigma_{m} \times \Sigma_{n-m}\). Let us write \(f\) as a function on two sets of variables \(f(A, B), |A| = m, |B| = n - m\). It is symmetric with respect to \(A\)-variables and \(B\)-variables. Let

- \(T = \{t_{1}, t_{2}, \ldots, t_{n}\}\)
- \(Z_{1} = \{z_{1}, z_{2}, \ldots, z_{m}\}\)
- \(Z_{2} = \{z_{m+1}, z_{m+2}, \ldots, z_{n}\}\)
- \(Z = Z_{1} \cup Z_{2}\)

Then

\[
p_{1}(E) = \sum_{A \subset T, \ |A| = m} \frac{f(A, A^{o-1})}{[A^{o}/A]} = \frac{1}{m!(n-m)!} \text{Res}_{Z=0,\infty} \frac{f(Z_{1}, Z_{2}) \cdot [R(Z_{1})] \cdot [Z_{1}/Z_{2}] \cdot [R(Z_{2})] \cdot d\log(Z)}{[T/Z]}.
\]

\(^{1}\) The nonequivariant class can be written as \(- (2G_{32}(\gamma) + 7G_{33}(\gamma) + 2G_{41}(\gamma) + 13G_{42}(\gamma) + 37G_{43}(\gamma) + 64G_{44}(\gamma) + 8G_{51}(\gamma) + 40G_{52}(\gamma) + 106G_{53}(\gamma) + 196G_{54}(\gamma) + 273G_{55}(\gamma))\).
Another formula is given in [1, Prop 5.1]:

\[ p_1(E) = \text{Res}_{Z=0,\infty} \frac{f(Z) \cdot [R^+(Z)] \cdot d\log(Z)}{[T/Z]} \cdot \left[ R + (Z) \right]. \]

Here, there is no factor \( \frac{1}{m!(n-m)!} \), and the numerator is much simpler.

### 8.2 Flag manifold

In [1, Prop 5.3], Allman gives the following formula for the push-forward on the full flag manifold. Let \( Fl(n) = GL_n(\mathbb{C})/B \) be the full flag manifold. Let \( E \) be a vector bundle over \( Fl(n) \) associated to a representation of the maximal torus. Let \( f \in K^T(pt) \) be the class of this representation. Let

- \( T = \{ t_1, t_2, \ldots, t_n \} \)
- \( Z = \{ z_1, z_2, \ldots, z_n \} \)

Then, the formula for the push-forward is the following:

\[ p_1(E) = \sum_{\sigma \in \Sigma_n} \frac{f(\sigma T)}{[R^+(\sigma T^{-1})]} = \text{Res}_{Z=0,\infty} \frac{f(Z) \cdot [R^+(Z)] \cdot d\log(Z)}{[T/Z]} \cdot \left[ R + (Z) \right]. \]

In particular, if

\[ f(T) = \prod_{i=1}^{n} \left( 1 - \frac{1}{t_i} \right)^{a_i + n - i}, \]

we obtain the formula from [21, Prop. 3.3] for Grothendieck polynomial

\[ G(a_1, a_2, \ldots, a_n)(t_1, t_2, \ldots, t_n). \]

### 8.3 G2/B

The formula (1) is valid for \( G_2/B \) because the \( G_2/B \) embeds into \( Fl_{1,2}(\mathbb{C}^7) \) and the class of \( G_2/B \) comes from the Grassmannian \( Gr(2, 7) \) via pull-back:

\[ [G_2/B] = \pi^*[G/P_2], \]

where \( \pi : Fl_{1,2}(\mathbb{C}^7) \to Gr(2, 7) \) is the natural projection.

### 8.4 Quadric

The homogeneous space for \( O(2n) \) consisting of isotropic lines \( IG(1, 2n) \subset \mathbb{P}^{2n-1} \) does not fit to the previous schemes. Suppose \( E \) is a vector bundle over \( IG(1, 2n) \).
which is associated with a representation of $\mathbb{C}^* \times O(2n-2)$. Its character $f \in K^T(pt)$ is symmetric with respect to permutations of $t_2, t_3, \ldots, t_n$ and with exchanging $t_i$ with $t_{i-1}$ for $i \geq 2$. Let

- $T = \{t_1, t_2, \ldots, t_n\}$
- $Z_2 = \{z_2, z_3, \ldots, z_n\}$
- $Z = \{z_1\} \cup Z_2$

One has

$$p_t(E) = \frac{f(a, T \setminus \{a\})}{|(T^{\pm 1} \setminus \{a, a^{-1}\})/[a]|} = \frac{1}{2^{n-1}} \text{Res}_{z=0, \infty} \frac{f(z_1, Z_2) \cdot [z_1^{-2}] \cdot [Z^{-1} \otimes Z_2^{-1}] \cdot [R^+(Z)] \cdot \text{dlog}(Z)}{[T^{\pm 1}/Z]}$$

This case is really different from the previous ones. It cannot be reduced to the push-forward of classes expressed by symmetric function in groups of variables. Here, the second set of variables is invariant with respect to the action of $\mathbb{Z}_2^{n-1} \rtimes \Sigma_{n-1}$. We leave this formula as an exercise for the reader. Our proof is just by an elementary calculus of functions.

**Appendix: About computations**

Let us briefly discuss the methods of computations. To find the push-forward of a class in K-theory given by the polynomial $f(t_1, t_2)$, we apply the localization formula (1). The Weyl group of $G_2$ is isomorphic to the dihedral group $D_{12}$. The fixed points of $G_2/P_2$ are indexed by the cosets $D_{12}/\mathbb{Z}_2$. The contribution coming from the coset of the identity is equal to

$$\theta(t_1, t_2) = \frac{f(t_1, t_2)}{(1-t_1)(1-t_2)(1-t_1 t_2)(1-\frac{t_1^2}{t_2})(1-\frac{t_2^2}{t_1})}.$$ 

The remaining fixed points lie in the orbit of $\mathbb{Z}_6$. The action of the generator of $\mathbb{Z}_6$ is given by the substitution:

$$\xi: (t_1, t_2) \mapsto (t_2, t_2/t_1).$$

The push-forward $p_{G_2!}$ is equal to the sum of six quotients:

$$\sum_{k=0}^{5} \theta(\xi^k(t_1, t_2)).$$

We find that the push-forwards of the Grothendieck polynomials for the partitions

$\left[0\right], \left[1\right], \left[2\right], \left[11\right], \left[3\right], \left[21\right], \left[31\right], \left[22\right]$
are equal to one. Moreover,

\[ p_{G_2!}(G_4) = p_{G_2!}(G_{41}) = p_{G_2!}(G_{32}) = 2, \quad p_{G_2!}(G_{33}) = 0. \]

The remaining values of \( p_{G_2!}(G_I) \in K^T(pt) \) can be expressed in variables

\[ A = 3 - t_1 - \frac{1}{t_2} - \frac{t_2}{t_1}, \quad B = 3 - t_2 - \frac{1}{t_1} - \frac{t_1}{t_2} \]

- \( p_{G_2!}(G_5) = p_{G_2!}(G_{51}) = p_{G_2!}(G_{42}) = A + B \)
- \( p_{G_2!}(G_{52}) = A^2 + B^2 + AB - 2A - 2B \)
- \( p_{G_2!}(G_{43}) = AB - A - B \)
- \( p_{G_2!}(G_{53}) = AB(A + B - 5) \)
- \( p_{G_2!}(G_{44}) = -AB \)
- \( p_{G_2!}(G_{54}) = A^2B^2 + A^3 + B^3 - 3A^2B - 3AB^2 - 3A^2 - 3B^2 + 8AB \)
- \( p_{G_2!}(G_{55}) = -A^2B^2 - A^3 - B^3 + 2A^2B + 2AB^2 + 2A^2 + 2B^2 - 4AB \)

Next, we compute the intersection matrix

\[ m_{I, J} = p!(G_I \cdot G_J) \]

for the partitions \( I \) and \( J \) contained in the \( 5 \times 2 \) rectangle. This is done by the application of the formula (2). We obtain a matrix of the size \( 21 \times 21 \). Its entries are Laurent polynomials in \( t_1 \) and \( t_2 \). The entries again can be expressed in \( A \) and \( B \) as symmetric polynomials. The matrix after reduction of variables is still quite large, and hence we do not give its precise form, see [23]. It is remarkable that the determinant of this matrix is equal to \( -1 \). We invert the intersection matrix, and we find that

\[ p_{G_2!}(G_I) = p!(G_I \cdot (2G_{41} + 2G_{32} - G_{33} - 3G_{42} + G_{43} + \left( A + B \right)(G_{21} - G_{22} - G_{31} + G_{32}))). \]

for all partitions \( I \). It follows that

\[ [G_2/P_2] = 2G_{41} + 2G_{32} - G_{33} - 3G_{42} + G_{43} + \left( A + B \right)(G_{21} - G_{22} - G_{31} + G_{32}) . \]
