2 Institute of Computer Science, Polish Academy of Sciences, Warsaw, Poland

Abstract. The COVID-19 pandemic has influenced virtually all aspects of our lives. Across the world, countries have applied various mitigation strategies, based on social, political, and technological instruments. We postulate that multi-agent systems can provide a common platform to study (and balance) their essential properties. We also show how to obtain a comprehensive list of the properties by “distilling” them from media snippets. Finally, we present a preliminary take on their formal specification, using ideas from multi-agent logics.

Key words: COVID-19; mitigation strategies; specification; multi-agent logics

1. INTRODUCTION

COVID-19 has influenced virtually all aspects of our lives. Across the world, countries applied wildly varying mitigation strategies for the epidemic, ranging from minimal intrusion in the hope of obtaining “herd immunity”, to imposing severe lockdowns on the other extreme. It seems clear at the first glance what all those measures are trying to achieve, and what the criteria of success are. But is it really that clear? Quoting an oft-repeated phrase, with COVID-19 we fight an unprecedented threat to health and economic stability [1]. While fighting it, we must protect privacy, equality and fairness [2] and do a coordinated assessment of usefulness, effectiveness, technological readiness, cyber security risks and threats to fundamental freedoms and human rights [3]. Taken together, this is hardly a straightforward set of goals and requirements. Thus, paraphrasing [3], one may ask:

What problem does an anti-COVID strategy solve exactly?

Even a quick survey of news articles, manifestos, and research papers published since the beginning of the pandemic reveals a diverse landscape of postulates and opinions. Some authors focus on medical goals, some on technological requirements; others are concerned by the economic, social, or political impact of a containment strategy. The actual stance is often related to the background of the author (in case of a researcher) or their information sources (in case of a journalist). Moreover, the authors advocating a particular aspect of the strategy most often neglect all the other aspects. We propose that the field of multi-agent systems can offer a common platform to study all the relevant properties, due to its interdisciplinary nature [4, 5], well developed theories of heterogeneous agency [6, 7], and a wealth of formal methods for specification and verification [8, 5, 9].

This still leaves the question of how to gather the actual goals and requirements for a COVID-19 mitigation strategy. One way to achieve it is to look at what is considered relevant by the general public, and referred to in the media. To this end, we collected a number of news quotes, ordered them thematically and with respect to the type of concern, and presented in [10], see Section 2 for more details. Then, we took the quotes, and distilled a comprehensive list of goals, requirements, and risks. The list is presented in Section 3. In Section 4, we make the first step towards a formalization of the properties in multi-agent logics. We conclude in Section 5.

Besides potential input to the design of anti-COVID-19 strategies, the main contribution of this paper is methodological: we demonstrate how to obtain a comprehensive specification of properties for complex Multi-Agent Systems (MAS) by searching for hints in the public space.

2. EXTRACTING REQUIREMENTS FROM NEWS CLIPS

Specification of properties is probably the most neglected part of formal verification for MAS. The tools usually come with examples of how to model the system [11, 12, 13, 14]. For a complex multi-agent scenario, however, it is not clear where the specifications of relevant properties should come from.

Mitigating COVID-19 illustrates the point well. Research on mitigation measures is typically characterized by: (a) strong focus on the native domain of the authors, and (b) focus on the details, rather than the general picture. In order to avoid “overlooking the forest for the trees,” we came up with a different methodology.

A. Methodology

We have looked for relevant phrases that appeared in the media, with no particular method of source selection. Then, we extracted the properties, and whenever possible generalized statements on specific measures to the mitigation strategy in general. Finally, we sorted them thematically, and divided into 3 categories: goals, additional requirements, and potential risks and threats. While most of the collected snippets focus on digital contact tracing, the relevance of the requirements goes well beyond that, and applies to all the aspects of the epidemic.

We emphasize that we do not endorse the opinions being presented in the quotes. We also do not comment on their con-

*e-mail: wojciech.jamroga@uni.lu
tent. We merely use the quotes to collect relevant keywords and conceptual categories. The reasons are twofold. First, we are not competent enough to assess the merits of most of the statements, in particular the ones concerning the medical, epidemiological, economic, ethical, legal, and social aspects. Secondly, the aim of this paper is to collect plausible requirements, i.e., ones that are considered relevant by (at least some) experts. Clearly, no mitigation strategy can satisfy them all. A systematic analysis of which subset can be feasibly obtained, and how to weigh their relative importance, should follow as the next step through a consensus of multidisciplinary experts.

We present a sample of the quotes in the remainder of this section, namely the ones related to basic epidemiological goals, societal requirements, and data protection. A more comprehensive collection of “news clips” can be found in the technical report [10]. The resulting list of goals, requirements and threats will be presented in Section 3.

B. News Clips: Epidemiological Goals

Containment measures should slow the spread of the virus, decrease the transmission rate, and save lives:

- Contact tracing can be an important component of an epidemic response especially when the prevalence of infection is low. Such efforts are most effective where testing is rapid and widely available and when infections are relatively rare. [1]
- To best meet public health needs, digital technology should be able to trace the spread of the virus, identify dangerous Covid-19 clusters and limit further transmission. The essential goal is to register contacts between potential carriers and those who might be infected. [17]
- Researchers also calculated that the interventions had caused the reproduction number – how many people someone with the virus infects – to drop by an average of 82 percent, to below 1.0. [16]
- Smittestopp is an app that will help the health authorities to limit the transmission of coronavirus and alert users with text messages about close contact with infected persons. [21]
- Lockdowns prevented around 3.1 million deaths in 11 European countries [16]

C. News Clips: Impact on Society

Regarding the available measures in general, and contact-tracing apps in particular:

- The health minister, Greg Hunt, tweeted that [the Covid-safe app] was the key to being allowed to go back to watching football. [24]
- [The Covidsafe app] was sold as the key to unlocking restrictions (…) but as the country begins to open up, the role of the Covidsafe app in the recovery seems to have dropped to marginal at best. [24]
- As the global fight against the COVID-19 pandemic continues, much of the world is pinning its hopes of easing lockdowns on being able to quickly identify people who might have been exposed to the virus. [23]

C.1. Disinformation and Information Abuse

We worry that contact-tracing apps will serve as vehicles for abuse and disinformation, while providing a false sense of security to justify reopening local and national economies well before it is safe to do so. [1]

- Since the outbreak of COVID-19 there has been a rapid acceleration in the spread of mis- and disinformation. To control this, governments and social media platforms have sought to stringently regulate online content and promote official facts and figures from international health organisations. [15]

C.2. Potential for Discrimination and Social Divides

There is also a very real danger that these voluntary surveillance technologies will effectively become compulsory for any public and social engagement. [1]

- Protecting those communities who can be (…) harmed by the collection and exploitation of personal data. [1]
- There is also a real risk that these mobile-based apps can turn unaffected individuals into social pariahs, restricted from accessing public and private spaces or participating in social and economic activities. [1]

- There is a very real danger that these voluntary surveillance technologies will effectively become compulsory for any public and social engagement. [1]

- Protections need to be put in place to expressly prohibit economic and social discrimination on the basis of information and technology designed to address the pandemic. [1]
C.3. Political Impact. The pandemic creates new space for political manipulation and changes the distribution of power:

- the issue of malicious use is paramount—particularly given this current climate of disinformation, astroturfing, and political manipulation. Imagine an unscrupulous political operative who wanted to dampen voting participation in a given district, or a desperate business owner who wanted to stifle competition. Either could falsely report incidences of coronavirus without much fear of repercussion. Trolls could sow chaos for the malicious pleasure of it. Protesters could trigger panic as a form of civil disobedience. A foreign intelligence operation could shut down an entire city by falsely reporting COVID-19 infections in every neighborhood. [1]

D. News Clips: Data Protection and Misuse of Data

Here, the key questions are:

What data will they collect, and who is it shared with [22] as well as

how data is collected, stored and deleted [25]

In particular, it is often postulated to have less state access and control over user data [20]

the limits on the type of data collection are the core concern for states. [26]

In Singapore, for example, the TraceTogether app can be used only by its health ministry to access data. It assures citizens that the data is to be used strictly for disease control and will not be shared with law enforcement agencies for enforcing lockdowns and quarantine. [27]

[Australia:] Only health officials in the states can access the data, and you can’t be forced to download it. [24]

The app does not collect any of your personal data. [18]

D.1. Risks and Threats

- collection of data on centralised servers: Aside from the risk to privacy, collecting millions of datasets of personal information in a single place could be viewed as somewhat of a treasure trove. [28]

- if the [central] database is hacked, the anonymity provided by rotating pseudonyms is nullified, and individuals can be more easily tracked. Plus, says Kreps, “there’s a risk of function creep and state surveillance”. “I have little faith in government’s ability to keep data like this secure,” says Green. [23]

- data breaches can also come through cyberattacks or independent actors within an agency [29]

In particular, the collected information should not be exploited for commercial purposes:

existing regulations don’t address whether data can be shared across agencies or if it can be sold by a third party for non-Covid-19 tracking. [29]

We found code relating to Google’s advertising and tracking platforms in 17 contact tracing apps. (...) We also found code that enabled varying levels of integration with Facebook in seven apps. [15]

The full list of collected quotes can be found in [10].

3. GOALS AND REQUIREMENTS FOR COVID-19

Based on the quotes, we identified the following goals, requirements and potential vulnerabilities of a containment strategy.

A. Epidemiological and Health-Related Concerns

COVID-19 is first and foremost a threat to people’s health. Accordingly, we begin with requirements related to this aspect.

A.1. Epidemiological Goals. The goal of the mitigation strategy in general, and digital measures in particular, is to:

- provide an epidemic response [1]
- bring the pandemic under control [2]
- slow the spread of the virus [15, 18, 1, 20, 21, 17]
- prevent deaths [16]
- reduce the reproduction rate of the virus [16].

The specific goals of digital measures are to:

- trace spread of the virus and identify COVID-19 clusters [17]
- find potential new infections [30]
- register contacts between potential carriers [17]
- deter people from breaking quarantine [27]

Note that the above goals are different (though clearly related). For example, reducing the reproduction rate and preventing deaths are not equivalent, and may require different concrete countermeasures.

Requirements:

1. The efforts must meet public health needs best [1, 17].
2. Digital measures should complement traditional ones [1, 30].
3. They should be designed to help the health authorities [21].

A.2. Effectiveness of Epidemic Response. Requirements:

1. The strategy should be effective [1, 3].
2. It should make a difference [31].

Risks and threats:

- Inaccurate detection of carriers and infected people due to the limitations of the technology and the underlying model of human interaction [1]
- Adverse impact on relaxation of lockdowns [15]
- Misguided assurance that going out is safe [1].
A.3. Information Flow Requirements. The strategy should:
1. allow to identify people who might have been exposed [23]
2. allow to alert those people [2, 21, 30, 32].
3. The identification and notification must be rapid [23, 2].

A.4. Monitoring. The containment strategy should enable:
1. monitoring the state of the pandemic, e.g., the outbreaks and the spread of the virus [32, 33]
2. monitoring the behavior of people, in particular if they are following the rules [34]
3. to monitor the effectiveness of the strategy [28].

A.5. Tradeoffs. There are tradeoffs between effective containment of the epidemic and other concerns, such as privacy and protection of fundamental freedoms [35, 27, 32, 17, 28]. Thus, the strategy should
1. strike the right balance between different concerns [17].

We will see more detailed tradeoff-related requirements in the subsequent sections.

B. Economic and Social Impact
Most measures to contain the epidemic have strong social and economic impact (cf. lockdown).

B.1. Economic Stability. The containment strategy should:
1. minimize the cost to local economies and the negative impact on economic growth [1, 16]
2. allow for return to normal economy and society and make resumption of economic and social activities safer [30, 24].

B.2. Social and Political Impact. The containment strategy (and digital measures in particular) should:
1. ease lockdowns and home confinement [1, 3, 23, 24]
2. minimize adverse impact on social relationships and personal well-being [11]
3. prohibit economic and social discrimination on the basis of information and technology being part of the strategy [1]
4. protect the communities that can be harmed by the collection and exploitation of personal data [1].

Risks and threats:
- Little knowledge about social impact of the measures [22]
- Discrimination and creation of social divides [1, 36]
- Disinformation and information abuse [1, 15]
- Providing a false sense of security [1]
- Political manipulation, creating social unrest, and dishonest competition by false reports of coronavirus [1]
- Too much political influence of IT companies on the decisions of sovereign democratic countries [17].

B.3. Costs, Human Resources, Logistics. Requirements:
1. The financial cost of the measures should be minimized [37]
2. Minimization of the involved human resources [34, 1]
3. Timeliness [37]
4. Coordination between different institutions and authorities [26, 38] and establishment of common standards [26].

C. Ethical and Legal Aspects
In this section, we look at requirements that aim at the long-term robustness and resilience of the social structure.

C.1. Ethical and Legal Requirements
1. The mitigation strategy must be ethically justifiable [2]
2. Measures should be necessary, proportionate, legitimate, just, scientifically valid, and time-bound [2, 15, 39, 34, 36]
3. They should not be invasive [27] and must not be done at the expense of individual civil rights [20, 22, 36]
4. Means of protection should be available to anyone [2]
5. They should be voluntary [22, 18]
6. Measures must comply with legal regulations [36, 35, 40]
7. Implementation and impact must also be considered [2, 15]
8. Impact assessment is to be conducted and made public [36].

C.2. Risks and Threats
a. Serious and long-lasting harms to fundamental rights and freedoms [2]
b. Costs of not devoting resources to something else [2]
c. Measures that support extensive physical surveillance [15]
d. Social costs of mandatory use of digital measures, collecting sensitive information, and sharing the data with the government [27, 23]
e. Censorship practices [15].

D. Privacy and Data Protection
Privacy-related issues for COVID-19 mitigation strategies have triggered heated discussion and substantial media coverage.

D.1. General Privacy Requirements
1. The strategy should be designed with privacy and information security in mind [1, 30, 22]
2. It should be anonymous under data protection laws, i.e., it cannot lead to the identification of an individual [31]
3. Information about users must be protected at all times [18]
4. The design should include recommendations for how backend systems should be secured, and identify vulnerabilities as well as unintended consequences [1].

Risks and Threats:
- Lack of clear privacy policies [15, 29, 22]
- Exploitation of personal information by authorities or third parties [29, 15, 41], in particular live or near-live tracking of users’ locations and linking sensitive personal information to an individual [41]
**Requirements for COVID-19 Mitigation Strategies**

c. Linking different datasets at some point in the future [40]
d. Alerts can be too revealing [42]
e. Possibility to work out who is associating with whom [35].

**D.2. Data Protection and Potential Misuse of Data.** Here, the key question is: What data is collected and who is it shared with? [22, 1] This leads to the following requirements:

1. Clear and reasonable limits on the data collection types [26, 27, 18, 1, 30]
2. Limitations on how the data is used [22]
3. In particular, the data is to be used strictly for disease control and not shared with law enforcement agencies [27, 24]
4. Less state access and control over user data [20]
5. Data collection should be minimized [22] and based on informed consent of the participants [17]
6. Giving access to one’s data should be voluntary [22]
7. One should have the right to access their own data [21, 35]
8. ...and ability to delete their personal information [21, 35]
9. For digital measures, the user should be able to remove the software and disable more invasive features [21].

**Risks and threats:**
- a. Data storage that can be hacked and exploited [28, 23, 15]
- b. Data breaches due to insider threats [29]
- c. Function creep and state surveillance [23]
- d. Sharing data across agencies or selling to third party [29, 15]
- e. Integration with commercial services [15].

**D.3. Sunsetting and Safeguards.** Requirements:

1. Measures must be terminated as soon as possible [34, 1, 21]
2. Data should be eventually or even periodically destroyed [34, 22, 21, 35, 1, 30], in particular when it is no longer needed to help manage the spread of coronavirus [18]
3. Transparency of data collection [22]
4. There should be clear policies to prevent abuse [22]
5. Privacy must be backed up with clear lines of accountability and processes for evaluation and monitoring [40]
6. Judicial oversight must be provided [1]
7. Safeguards should be backed by an independent figure [34].

**Risks and threats:**
- a. Surveillance might continue after the pandemic [41]
- b. Data can stay with the government longer than necessary [34].

**D.4. Impact of Privacy on Epidemiological and Social Concerns.** Requirements:

1. People must get the information they need to protect themselves and others [42]
2. There must be protections against economic and social discrimination based on information and technology designed to fight the pandemic, in particular w.r.t. communities vulnerable to collection and exploitation of personal data [1]
3. Information should be used in such a way that people who fear being judged will not put other people in danger [42].

**Risks and threats:**
- a. Fear of social stigma [42]
- b. Online judgement and ridicule [42].

**D.5. Privacy vs. Epidemiological Efficiency.** There is a tradeoff between protecting privacy vs. collecting all the information that can be useful in fighting the epidemic:

- Privacy hinders making the best possible use of the data, including analysis of the population, contact matching, modeling the network of contacts, enabling epidemiological insights such as revealing clusters and superspreaders, and providing advice to people [35, 23, 24]
- On the other hand, privacy-preserving solutions put users in more control of their information and require no intervention from a third party [35].

The relationship is not simply antagonistic, though:

- Privacy is instrumental in building trust. Conversely, lack of privacy undermines trust, and hinders the epidemiological, economic, and social effects of the mitigation activities [29].

Thus, while it might be necessary to waive users’ privacy in the short term to contain the epidemic, one must look for mechanisms such that exploiting the risks would require significant effort by the attackers for minimal reward [23].

**E. User-Related Aspects**

The measures must be adopted in order to make them effective.

**E.1. User Incentives.** Goals:

i. High acceptance rate for the mitigation measures [30].
ii. Creating incentives and overcoming incentive problems for individual people to adopt the strategy [1]

**Risks and threats:**
- a. Lack of immediate benefits for the participants [1]
- b. Perceived privacy and security risks [30]
- c. Some measures can divert attention from more important measures, and make people less alert [43]
- d. Creating false sense of security from the pandemic [33].

**E.2. Adoption and its Impact.** Requirements:

1. Enough people should download and use the app to make it effective [30, 22, 23, 44]. Note: this requirement is graded rather than binary [45, 46].

**Risks and threats:**
- a. Lack of users’ trust [31, 29], see also the connection between privacy and trust in Section D.5
- b. Authorities’ lack of social knowledge and empathy [32].
F. Technological Aspects

General requirements:
1. The measures and tools must be operational [35, 34]
2. In particular, they should be compatible with their environment of implementation [40]
3. Design and implementation should be transparent [22, 47].

Specific requirements for digital measures:
1. They should be compatible with most available devices [40]
2. Reasonable use of battery [40]
3. Usable interface [40]
4. Accurate measurements of how close two devices are [23]
5. Cross-border interoperability [48]
6. Possibility to verify the code by the public and experts [47].

G. Evaluation and Learning for the Future

COVID-19 mitigation activities should be rigorously assessed. Their outcomes should be used to extend our knowledge, and better defend ourselves in the future. The main goal here is:

i. to use the collected data in order to develop efficient infection control measures and gain insight into the effect of changes to the measures for fighting the virus [21, 35].

Requirements:
1. A review and exit strategy should be defined [2]
2. Before implementing the measures, an institutional assessment is needed of their usefulness, effectiveness, technological readiness, cyber-security risks and threats to fundamental freedoms and human rights [3]
3. After the pandemic, there must be the society’s assessment whether the strategy has been effective and appropriate [42]
4. The assessments should be conducted by an independent body at regular intervals [2].

4. TOWARDS FORMAL SPECIFICATION

Here, we briefly show how the requirements presented in Section 3 can be rewritten in a more formal way. To this end, we use modal logics for distributed and multi-agent systems that have been in constant development for over 40 years [49, 50, 7, 51, 52, 53]. The reasons for this choice are as follows. First, the logics have been developed to address the dynamics of complex heterogeneous systems that involve interaction between autonomous processes – exactly what we are dealing with here. Secondly, they allow for a natural separation of concerns by using different modalities for different aspects of the system and its participants (knowledge, beliefs, intentions, temporal evolution, strategic planning, social norms, available resources, etc.). To this day, they have been applied in numerous case studies to formalize multi-agent scenarios.

Thirdly, the logics are based on intuitive Kripke-style semantics that interprets the different modalities in a reasonably uniform way. Moreover, models can be visualized as graphs that are easy to explain, and can be scrutinized by non-experts. Fourthly, many relevant requirements can be specified in the propositional variants of MAS logics, i.e., by formulas without quantifiers. This makes reading the formulas somewhat easier. Even more importantly, propositional formulas often allow for decidable model checking with manageable complexity, which gives hope for automated verification. Last but not least, in parallel with the formal framework, the MAS community have been developing model checking tools that can be used to verify some of the requirements against models of the pandemic. We mention some of the tools, and speculate on the possibilities for actual verification at the end of this section.

Note that the following specifications are only semi-formal, as we do not fix the models nor give the precise semantics of the logical operators and atomic predicates. We leave that step for the future work.

A. Temporal Properties

The simplest kind of requirements are those that refer to achievement or maintenance of a particular state of affairs. They can be expressed by formulas of the branching-time logic $\text{CTL}^*$ [49], with path quantifiers $E$ (there is a path), $A$ (for all paths), and temporal operators $\Diamond$ (in the next moment), $\Box$ (sometime from now on), $E$ (always from now on), and $U$ (until). For example, the epidemiological goals in Section 3A can be tentatively rewritten as the following $\text{CTL}^*$ formulas:

(i) $A \Diamond (\text{outbreak} \rightarrow \text{response})$: for all possible execution paths, if outbreak holds at some point, then response must hold at a later point on the same path. That is, whenever an outbreak occurs, a response will be eventually provided;
(ii) $A \Diamond \text{controlPandemic}$: the pandemic will be eventually brought under control;\textsuperscript{1}
(iii) and (v) $\forall n. (R0 = n) \rightarrow A \Diamond (R0 < n)$: the reproduction rate of the virus will decrease below the current level;
(iv) $A \Diamond \neg (\text{#deaths} > k)$: the number of fatalities will never exceed $k$, for a reasonably chosen $k$.

The above formulas are supposed to serve as the first formal approximations of the requirements. In actual analysis, they should be iteratively refined, taking into account the desired level of granularity and the variables available in the model.

B. Combining Temporal and Epistemic Aspects

Many important properties of multi-agent systems refer to agents’ knowledge and its dynamics. In our case, this concerns for example the information flow and monitoring requirements in Sections 3A.3 and 3A.4. Such properties can be expressed by the combination of $\text{CTL}^*$ with epistemic operators $K_a \varphi$ (“$a$ knows that $\varphi$”). For instance, the information flow requirement (1) in Section 3A.3 can be formalized as

$$A \Diamond t \rightarrow A \Diamond K_a \Diamond \text{exposed}_t,$$

where $a$ is the authority supposed to identify vulnerable people. A more faithful transcription can be obtained using the past-time operator $\Diamond^{-1}$ (sometime in the past) [54] with

$$(\Diamond^{-1} \text{exposed}_t) \rightarrow A \Diamond K_a (\Diamond^{-1} \text{exposed}_t).$$

\textsuperscript{1}In fact, a better specification is given by $A \Diamond \Box \text{controlPandemic}$, saying that the pandemic is not only brought, but also kept under control.
Requirements for COVID-19 Mitigation Strategies

saying that if exposed has held at some point in the past, then a will eventually know about it. Likewise, the information flow requirement (2) can be captured by

\[ K_\alpha (\rightarrow \neg \text{exposed}) \rightarrow \text{A} \Diamond K_i (\rightarrow \neg \text{exposed}) , \]

saying that, if a knows that i has been exposed, then i will eventually know about it, too.

Similar temporal-epistemic formulas may be used to express some privacy-related requirements, e.g.,

\[ \forall j \neq i. \text{A} \square \neg K_j (x = i) \land \neg K_j (x \neq i) \]

tentatively captures the anonymity of person i wrt. the database entry represented by x, see requirement (2) in Section 3D.1.

C. Strategic Requirements

Demanding that something must happen on all paths is often too strong. It often suffices that the responsible agent(s) can follow a recipe (formally, a strategy) that guarantees the desirable outcome. To this end, the temporal and epistemic patterns can be refined by replacing path quantifiers A, E with strategic operators \( \langle\langle A\rangle\rangle \) of the logic ATL* [52, 53], where \( \langle\langle A\rangle\rangle \varphi \) says that "the agents in A have a strategy to bring about \( \varphi \)". For example, the information flow requirements (1) and (2), discussed in the previous section, can be rewritten as

\[ (\rightarrow \neg \text{exposed}) \rightarrow \langle\langle a\rangle\rangle \Diamond K_\alpha (\rightarrow \neg \text{exposed}) , \]
\[ K_\alpha (\rightarrow \neg \text{exposed}) \rightarrow \langle\langle a\rangle\rangle \Diamond \langle\langle i\rangle\rangle \Diamond K_i (\rightarrow \neg \text{exposed}) . \]

The former says that if i has been exposed, then the health authority a has a strategy to eventually realize that. We leave the interpretation of the latter to the interested reader.

Strategic operators are also useful in formalizing the access control properties in Section 3D.2. For instance, requirement (6) can be formalized by the formula

\[ \langle\langle i\rangle\rangle \Diamond \text{access}(a, \text{data}) \land \langle\langle i\rangle\rangle \square \neg \text{access}(a, \text{data}) \]

expressing that i has a strategy which grants authority a with access to her data, and another strategy that never allows it.

D. Time Bounds, Mental Effort, and Bounded Resources

For some requirements, the temporal and strategic operators should be combined with bounds imposed on the execution time [55, 56], mental complexity [57], and/or resources needed to accomplish the tasks [58, 59]. For example, the identification requirement (1), discussed above, can be refined as:

\[ (\rightarrow \neg \text{exposed}) \rightarrow \langle\langle a\rangle\rangle \Diamond \forall t \leq 48h K_\alpha (\rightarrow \neg \text{exposed}) \]

That is, the authority a should identify the exposed person in at most 48 hours from the exposure. Similarly, the notification requirement (2) becomes:

\[ K_\alpha (\rightarrow \neg \text{exposed}) \rightarrow \langle\langle a\rangle\rangle \Diamond \forall c \leq 1h \langle\langle i\rangle\rangle \text{compl} \leq 5 \Diamond K_i (\rightarrow \neg \text{exposed}) , \]

based on the assumption that a should notify i within 1 hour of detecting i’s exposure to the virus, and i should have a simple strategy (of complexity at most 5) to infer the relevant knowledge from the notification.

E. Probabilistic Extensions

Many events have probabilistic execution, e.g., actions may fail with some small probability. Scenarios with probabilistic events can be modeled by variants of Markov decision processes, and their properties can be specified by a probabilistic variant of CTL* [60] or ATL* [61]. For instance, formula

\[ \langle\langle a\rangle\rangle P \geq 0.99 \rightarrow \langle\langle i\rangle\rangle \text{comp} \leq 5 \Diamond K_i (\rightarrow \neg \text{exposed}) . \]

refines the previous specification by demanding that the authority can successfully notify i with probability at least 99%.

F. Towards Formal Verification of Mitigation Strategies

Ideally, one would like to automatically evaluate COVID-19 strategies with respect to the requirements, and choose the best mitigation policy. A number of model checking tools have been developed over the past 30 years, including Uppaal [12] for temporal and time-bounded properties, MCMAS [11] for temporal-epistemic and strategic specifications, STV [14] for strategic agents with imperfect information, and PRISM [62] for stochastic multi-agent systems. In the future, we plan to use a selection of those tools to formally verify our formulas over micro-level models created to simulate and predict the progress of the pandemic [63, 64, 65, 66].

As we already pointed out, different requirements may be in partial conflict. Thus, selecting an optimal mitigation strategy may require solving a multicriteria optimization problem [67, 68, 69], e.g., by identifying the Pareto frontier and choosing a criterion to select a point on the frontier.

5. CONCLUSIONS

In this paper, we make the first step towards a systematic analysis of strategies for effective and trustworthy mitigation of the current pandemic. The strategies may incorporate medical, social, economic, as well as technological measures. Consequently, there is a large number of medical, social, economic, and technological requirements that must be taken into account when deciding which strategy to adopt. For computer scientists, the latter kind of requirements is most natural, which is exactly the pitfall that a computer scientist must avoid. The goals (and acceptability criteria) are much more diverse, and we must consciously choose a solution that satisfies the multiple criteria to a reasonable degree. We suggest that formal methods for MAS provide an excellent framework for that. We also propose a methodology to collect general requirements by mining the public information space (rather than scientific papers which are usually more technical and narrowly focused).

In the future, we would like to study how the technical requirements proposed in research articles refine the general requirements presented here. We also plan to use model checking in multi-agent logics to verify some of the requirements against the existing models of the pandemic.
