Counting orbits of integral points
in families of affine homogeneous varieties
and diagonal flows

Alexander Gorodnik        Frédéric Paulin
June 19, 2013

Abstract

In this paper, we study the distribution of integral points on parametric families of affine homogeneous varieties. By the work of Borel and Harish-Chandra, the set of integral points on each such variety consists of finitely many orbits of arithmetic groups, and we establish an asymptotic formula (on average) for the number of the orbits indexed by their Siegel weights. Our arguments use the exponential mixing property of diagonal flows on homogeneous spaces.

1 Introduction

In this paper, we investigate the asymptotic distribution of integral points on families of homogeneous algebraic varieties using dynamical systems techniques. Let \( L \) be a reductive algebraic group in \( \text{GL}_n(\mathbb{C}) \) defined over \( \mathbb{Q} \), and let \( X_v = Lv \) with \( v \in \mathbb{Q}^n \) be a Zariski-closed set. Borel-Harish-Chandra’s finiteness theorem [BHC, Theo. 6.9] says that the number of orbits of \( L(\mathbb{Z}) \) in \( X_v(\mathbb{Z}) \) is finite. We investigate the asymptotic behaviour of this number where the orbits are counted with suitable weights. Namely, to each orbit \([u] \in L(\mathbb{Z}) \backslash X_v(\mathbb{Z})\), we associate the Siegel weight

\[
w([u]) = \frac{\text{vol}(\text{Stab}_L(u)(\mathbb{Z}) \backslash \text{Stab}_L(u)(\mathbb{R}))}{\text{vol}(L(\mathbb{Z}) \backslash L(\mathbb{R}))}\]

and consider

\[
\beta(v) = \sum_{[u] \in L(\mathbb{Z}) \backslash X_v(\mathbb{Z})} w([u]).
\]

This quantity appears naturally in the study of spatial distribution of integral points. Given a cone \( \Omega \subset \mathbb{R}^n \) and a sequence of colinear vectors \( v_n \in \mathbb{Q}^n \) such that \( X_{v_n}(\mathbb{R}) \cap \Omega \) is bounded with boundary of measure zero and \( \text{Stab}_L(v_n) \) is a maximal subgroup of \( L \), it was shown in [EO], when \( L \) is semi-simple, that

\[
|X_{v_n}(\mathbb{Z}) \cap \Omega| \sim \text{vol}(\Omega) \cdot \beta(v_n) \quad \text{as} \quad \beta(v_n) \to \infty.
\]

\[\dagger\]Keywords: integral point, homogeneous variety, Siegel weight, counting, decomposable form, norm form, diagonalisable flow, mixing, exponential decay of correlation. AMS codes: 37A17, 37A45, 14M17, 20G20, 14G05, 11E20
Under some additional conditions on the varieties $X_{v_0}$, the asymptotics of $|X_{v_0}(\mathbb{Z})\cap \Omega|$ can be also computed using the Hardy–Littlewood circle method, so that the quantities $\beta(v_0)$ can be expressed in terms of local densities (see [BR, Oh1]). However, we emphasise that the asymptotic formula (1) and the Hardy–Littlewood method do not apply in general. In particular, it might happen that $\beta(v_0)$ does not converge to $\infty$ even though $\beta(v_n)$ does on average. Contrarily to the last two references, we also consider non semi-simple cases, which are useful for some examples.

The aim of this paper is to develop a direct argument that establishes an asymptotic formula for the quantities $\beta(v)$ on average. Our methods use flows on homogeneous spaces and dynamical systems techniques. We show that sums over $\beta(v)$ can be interpreted as volumes of intersections of two transversal submanifolds in a suitable homogeneous space. Then we prove that one of these submanifolds becomes equidistributed and deduce an asymptotic formula for the sums of $\beta(v)$'s.

Now we proceed to state our result precisely. Let $L$ be a reductive linear algebraic group defined and anisotropic over $\mathbb{Q}$, let $\pi : L \to \text{GL}(V)$ be a rational linear representation of $L$ defined over $\mathbb{Q}$ and let $\Lambda$ be a $\mathbb{Z}$-lattice in $V(\mathbb{Q})$ invariant under $L(\mathbb{Z})$. For every $v \in V(\mathbb{Q})$ whose orbit $X_v$ under $L$ is Zariski-closed in $V$, the number of orbits of $L(\mathbb{Z})$ in $X_v \cap \Lambda$ is finite. We will count these orbits using appropriate weights. For every $u \in X_v(\mathbb{Q})$ with stabiliser $L_u$ in $L$, define the Siegel weight of $u$ as

$$w_{L,\pi}(u) = \frac{\text{vol } (L_u(\mathbb{Z}) \backslash L_u(\mathbb{R}))}{\text{vol } (L(\mathbb{Z}) \backslash L(\mathbb{R}))},$$

using Weil’s convention for the normalisation of the measures on $L_u(\mathbb{R})$ (depending on the choice of a left Haar measure on $L(\mathbb{R})$ and of a $L(\mathbb{R})$-invariant measure on $X_v(\mathbb{R})$, see Section 2). These weights generalise the ones occurring in Siegel’s weight formula when $L$ is an orthogonal group (see for instance [Sie1, ERS], and [Vos, Chap. 5] for general $L$).

A particular case of the main results of this paper is the following one.

**Theorem 1** Let $G$ be a simply connected reductive linear algebraic group defined over $\mathbb{Q}$, without nontrivial $\mathbb{Q}$-characters. Let $P$ be a maximal parabolic subgroup of $G$ defined over $\mathbb{Q}$, and let $P = A M U$ be a relative Langlands decomposition of $P$, such that $A(\mathbb{R})_0$ is a one-parameter subgroup $(a_s)_{s \in \mathbb{R}}$, with $\lambda = \log \det (\text{Ad} a_1)|_{\Lambda} > 0$, where $\Lambda$ is the Lie algebra of $U(\mathbb{R})$. Let $\rho : G \to \text{GL}(V)$ be a rational representation of $G$ defined over $\mathbb{Q}$ such that there exists $v_0 \in V(\mathbb{Q})$ whose stabiliser in $G$ is $MU$. Let $L$ be a reductive algebraic subgroup of $G$ defined and anisotropic over $\mathbb{Q}$. Assume that $L P$ is Zariski-open in $G$ and that for every $s \in \mathbb{R}$, the orbit $X_s = \rho(L a_s)v_0$ is Zariski-closed in $V$.

Let $\Lambda$ be a $\mathbb{Z}$-lattice in $V(\mathbb{Q})$ invariant under $G(\mathbb{Z})$, and let $\Lambda^{\text{prim}}$ be the subset of indivisible elements of $\Lambda$. Assume $\rho$ to be irreducible over $\mathbb{C}$. Then there exist $c, \delta > 0$ such that, as $t$ tends to $+\infty$,

$$\sum_{0 \leq s \leq t} \sum_{|x| \in L(\mathbb{Z}) \backslash (X_s \cap \Lambda^{\text{prim}})} w_{L,\rho|_L}(x) = c e^{\lambda t} + O(e^{(\lambda-\delta)t}).$$

More precisely, let $G, P, A, M, U, V, L, \rho, v_0, (a_s)_{s \in \mathbb{R}}$ be as above ($\rho$ not necessarily irreducible). Endow $G(\mathbb{R})$ with a left-invariant Riemannian metric, for which the Lie algebras of $MU(\mathbb{R})$ and $A(\mathbb{R})$ are orthogonal, and the orthogonal of the Lie algebra of $P(\mathbb{R})$ is contained in the Lie algebra of $L(\mathbb{R})$. 

2
Theorem 2 There exists $\delta > 0$ such that, as $t$ tends to $+\infty$, 

$$
\sum_{0 \leq s \leq t} \sum_{x \in L(\mathbb{Z}) \setminus \rho(L(\mathbb{R})_0) \cap \rho(G(\mathbb{Z}))_0} w_{\ell, \rho}(x) \lambda \frac{\text{vol}((\mathbf{M}U(\mathbb{Z}) \setminus \mathbf{M}U(\mathbb{R})) \setminus \mathbf{A}(\mathbb{R})_0)}{\text{vol}(G(\mathbb{Z}) \setminus G(\mathbb{R}))} e^{\lambda t} + O(e^{(\lambda - \delta)t}).
$$

We will prove a more general version of this result in Section 2 without the maximality condition on $P$, involving the more elaborate root data of $P$, and without the simple connectedness assumption on $G$ (up to a slight modification of the Siegel weights), see Theorem 5 and Theorem 15.

We illustrate Theorem 1 by an example, which is new: we give an asymptotic estimate on the (weighted) number of inequivalent integral points on hyperplane sections of affine quadratic surfaces. More examples are given in Section 3.

Corollary 3 Let $n \geq 3$, let $q : \mathbb{C}^n \to \mathbb{C}$ be a nondegenerate rational quadratic form, which is isotropic over $\mathbb{Q}$, let $\ell : \mathbb{C}^n \to \mathbb{C}$ be a nonzero rational linear form, and let $L = \{ g \in \text{SL}_n(\mathbb{C}) : q \circ g = q, \ell \circ g = \ell \}$. For every $k \in \mathbb{Q}$, let $\Sigma_k$ be the set of primitive $x \in \mathbb{Z}^n$ such that $q(x) = 0$ and $\ell(x) = k$. Assume that the restriction of $q$ to the kernel of $\ell$ is nondegenerate and anisotropic over $\mathbb{Q}$. Then there exist $c = c(q, \ell) > 0$ and $\delta = \delta(q) > 0$ such that, as $r \to +\infty$, 

$$
\sum_{k \in [1, r]} \sum_{u \in (L(\mathbb{Z}) \setminus L(\mathbb{R})_0) \cap \Sigma_k} \text{vol}((L_u(\mathbb{Z}) \cap L(\mathbb{R})_0) \setminus (L_u \cap L(\mathbb{R})_0)) = c r^{n-2} + O( r^{n-2-\delta}).
$$

This result fits into the above program (up to a slight modification of the Siegel weights, see Section 2), by taking $V = \mathbb{C}^n$, $\Lambda = \mathbb{Z}^n$, and $\pi : L \to \text{GL}(V)$ the inclusion map, noting that $L$ is semisimple, and defined and anisotropic over $\mathbb{Q}$ as a consequence of the assumptions (see Section 3.2 for details, where we also explicit $c$).

Asymptotics of the number of integral points in affine homogeneous varieties has been extensively studied over the last decades using harmonic analysis and dynamical systems techniques. See for instance [ERS, DRS, EM, EMS, GO, Oh1, EO], as well as the surveys [Bab, Oh2]. Our results are quite different, since we are counting whole orbits, weighted by the Siegel weights, of integral points. The asymptotic formula that we obtain here is similar to the classical asymptotic formula for the number of integral quadratic forms averaged over discriminant, proved by Siegel in [Sie2]. More generally, if $V$ is a prehomogeneous vector space, analogous asymptotic formulas can be deduced from the analytic properties of the corresponding zeta functions that were studied by Sato and Shintani in [SS] (see also the monograph [Kim]). However, the dimension of $G_{\text{uni}}$ in Theorem 1 is typically much smaller than the dimension of $V$, and these methods don’t apply. We also note that we do not assume $X_\nu(\mathbb{R})$ to be an affine symmetric space or that the stabiliser is a maximal subgroup, contrarily to [DRS] and many other references. Another difference with the counting results of [EMS, Oh1, EO] is that these papers are using the dynamics of unipotent flows, as instead we are using here the mixing property with exponential decay of correlations of diagonalisable flows, in the spirit of [KMI] (see also [EM, BO]). We are using the proof of the main result of [PP] as a guideline.
Acknowledgment. We thank Jean-Louis Colliot-Thélène for discussions of our decomposable form result. The second author thanks the University of Bristol for a very fruitful short stay where this paper was conceived. The first author thanks the University Paris-Sud 11 for a month of invited professor where this paper was completed.

2 Counting Siegel weights

Here are a few notational conventions. By linear algebraic group $G'$ defined over a subfield $k$ of $\mathbb{C}$, we mean a subgroup of $\mathrm{GL}_N(\mathbb{C})$ for some $N \in \mathbb{N}$ which is a closed algebraic subset of $\mathcal{M}_N(\mathbb{C})$ defined over $k$, and we define $G'(\mathbb{Z}) = G' \cap \mathrm{GL}_N(\mathbb{Z})$. For every linear algebraic group $G'$ defined over $\mathbb{R}$, we denote by $G'(_R)_0$ the identity component of the Lie group of real points of $G'$. We denote by $\log$ the natural logarithm.

Let us first recall Weil’s normalisation of measures on homogeneous spaces. Let $G'$ be a unimodular real Lie group, endowed with a transitive smooth left action of $G'$ on a smooth manifold $X'$, with unimodular stabilisers. A triple $(\nu'_{G'}, \nu_{X'}, (\nu_{G'_{x}})_{x \in X'})$ of a left Haar measure $\nu'_{G'}$ on $G'$, a left-invariant (Borel, positive, regular) measure $\nu_{X'}$ on $X'$ and of a left Haar measure $\nu_{G'_{x}}$ on the stabiliser $G'_{x}$ of every $x \in X'$, is compatible if, for every $x \in X'$, for every $f : G' \to \mathbb{R}$ continuous with compact support, with $f_{x} : X' \to \mathbb{R}$ the map (well) defined by $gx \mapsto \int_{h \in G'_{x}} f(gh) \, d\nu_{G'_{x}}(h)$ for every $g \in G$, we have

$$\int_{G'} f \, d\nu''_{G'} = \int_{X'} f_{x} \, d\nu'_{X'}.$$  

Weil proved (see for instance [Wei, §9]) that, for every left-invariant measure $\nu_{X'}$ on $X'$, then

- for every left Haar measure $\nu'_{G'}$ on $G'$, there exists a unique compatible triple $(\nu'_{G'}, \nu_{X'}, (\nu_{G'_{x}})_{x \in X'})$.
- for every $x_{0} \in X'$, for every left Haar measure $\nu_{0}$ on $G'_{x_{0}}$, there exists a unique compatible triple $(\nu'_{G'}, \nu_{X'}, (\nu_{G'_{x}})_{x \in X'})$ with $\nu_{G'_{x_{0}}} = \nu_{0}$.

The following remark should be well-known, though we did not found a precise reference.

Lemma 4 If $(\nu'_{G'}, \nu_{X'}, (\nu_{G'_{x}})_{x \in X'})$ is a compatible triple, then for every $\ell \in G'$ and $x \in X'$, with $i_{\ell} : h \mapsto \ell h \ell^{-1}$ the conjugation by $\ell$, we have

$$\nu'_{G'_{i_{\ell}x}} = (i_{\ell})_{*} \nu'_{G'_{x}}.$$  

Proof. Let $x \in X'$, $\ell \in G'$, $H' = G'_{x}$ and $H'' = G'_{i_{\ell}x} = \ell H' \ell^{-1}$. Using the left invariance of $\nu_{X'}$ for the first inequality and the bi-invariance of the Haar measure on $G'$ for the last
one, we have, for every \( f : G' \to \mathbb{R} \) continuous with compact support,

\[
\int_{g'x \in X'} \int_{h' \in H'} f(g'h') d(i'_x)_* \nu_{G'_x}(h') \, d\nu_{X'}(g'\ell x)
\]

\[
= \int_{g'x \in X'} \int_{h' \in H'} f(\ell g'h') d(i'_x)_* \nu_{G'_x}(h') \, d\nu_{X'}(g'\ell x)
\]

\[
= \int_{g'x \in X'} \int_{h' \in H'} f(\ell g' h' \ell^{-1}) d\nu_{G'_x}(h') \, d\nu_{X'}(g'\ell x)
\]

\[
= \int_{gx \in X'} \int_{h' \in H'} f \circ i_x (gh') d\nu_{G'_x}(h') \, d\nu_{X'}(gx)
\]

\[
= \int_{G'} f \circ i_x d\nu_{G'} = \int_{G'} f \, d\nu_{G'}
\]

The result then follows by uniqueness. \( \square \)

In order to deal with non simply connected groups, we introduce a modified version of the Siegel weights.

Let \( L' \) be a reductive linear algebraic group defined and anisotropic over \( \mathbb{Q} \), let \( \pi : L' \to GL(V') \) be a rational linear representation of \( L' \) defined over \( \mathbb{Q} \), let \( v \in V'(\mathbb{Q}) \) be such that its orbit \( X'_u \) under \( L' \) is Zariski-closed in \( V' \), let \( u \in X'_u(\mathbb{Q}) \) and let \( L'_u \) be the stabiliser of \( u \) in \( L' \). We define the modified Siegel weight of \( u \) as

\[
w'_{L',\pi}(u) = \frac{\text{vol}(\{(L'_u(\mathbb{Z}) \cap L'(\mathbb{R})_0) \setminus (L'_u \cap L'(\mathbb{R})_0)\})}{\text{vol}(\{(L'(\mathbb{Z}) \cap L'(\mathbb{R})_0) \setminus L'(\mathbb{R})_0\})},
\]

using Weil’s convention for the normalisation of the measures on \( L'_u(\mathbb{R}) \) (depending on the choice of a left Haar measure on \( L'(\mathbb{R}) \) and of a \( L'(\mathbb{R}) \)-invariant measure on \( X'_u(\mathbb{R}) \)). Note that the denominator of the standard Siegel weight \( w_{L',\pi}(u) \) is an integral multiple (depending only on \( L' \)) of the denominator of the modified one, since \( (L'(\mathbb{Z}) \cap L'(\mathbb{R})_0) \setminus L'(\mathbb{R})_0 \) is a connected component of \( L'(\mathbb{Z}) \setminus L'(\mathbb{R}) \). But the ratio of the numerator of the Siegel weight by the numerator of the modified one may depend on \( u \).

Let us now describe the framework of our main result. Let \( G \) be a connected reductive linear algebraic group defined over \( \mathbb{Q} \). Let \( P \) be a (proper) parabolic subgroup of \( G \) defined over \( \mathbb{Q} \) (see for instance [BJ, §III.1], [Spr, §5.2]). Recall that a linear algebraic group defined over \( \mathbb{Q} \) is \( \mathbb{Q} \)-anisotropic if it contains no nontrivial \( \mathbb{Q} \)-split torus.

Recall that there exist a (nontrivial) maximal \( \mathbb{Q} \)-split torus \( S \) in \( G \) (contained in \( P \) and unique modulo conjugation by an element of \( P(\mathbb{Q}) \)), such that if \( \Phi^C = \Phi^C(G,S) \) is the root system of \( G \) relative to \( S \) (seen contained in the set of characters of \( S \)), if \( g^C_\beta \) is the root space of \( \beta \in \Phi^C \), then there exist a unique set of simple roots \( \Delta = \Delta_P \) in \( \Phi^C \) and a unique proper subset \( I = I_P \) of \( \Delta \), such that, with \( \Phi^C_+ \) the set of positive roots of \( \Phi^C \) defined by \( \Delta \) and \( \Phi^C_I \) the set of roots of \( \Phi \) that are linear combinations of elements of \( I \), if \( A \) is the identity component of

\[
\bigcap_{\alpha \in I} \ker \alpha,
\]

which is a \( \mathbb{Q} \)-split subtorus of \( S \), if \( U \) is the connected algebraic subgroup of \( G \) defined over \( \mathbb{Q} \) whose Lie algebra is

\[
u^C = \bigoplus_{\beta \in \Phi^C_+ - \Phi^C_I} g^C_\beta,
\]

\[5\]
then \(P\) is the semi-direct product of its unipotent radical \(U\) and of the centraliser of \(A\) in \(G\). Note that \(A\) is one-dimensional if \(P\) is a maximal (proper) parabolic subgroup of \(G\) defined over \(Q\) (that is, if \(\Delta - I\) is a singleton).

Let \(g\) be the Lie algebra of \(G(\mathbb{R})\). Using the multiplicative notation on the group of characters of \(S\), for every \(\alpha \in \Delta\), we define \(m_\alpha = m_\alpha, P \in \mathbb{N}\) by
\[
\prod_{\beta \in \Phi^+} \beta^{\dim_C (g^\beta \cap g)} = \prod_{\alpha \in \Delta} a^{m_\alpha}.
\]
Let \((\alpha^\vee)_{\alpha \in \Delta - I}\) in \(A(\mathbb{R})_0^{\Delta - I}\) be such that \(\log(\beta(\alpha^\vee))\) is equal to 1 if \(\alpha = \beta\) and to 0 otherwise. Let \(\Lambda^\vee\) be the lattice in \(A(\mathbb{R})_0\) generated by \((\alpha^\vee : \alpha \in \Delta - I)\). For every element \(T = (t_\alpha)_{\alpha \in \Delta - I}\) of \([0, +\infty)^{\Delta - I}\), let
\[
A_T = \{a \in A(\mathbb{R})_0 : \forall \alpha \in \Delta - I, \ 0 \leq \log(a(\alpha)) \leq t_\alpha\}.
\]
Recall that by the definition of a relative Langlands decomposition of the parabolic subgroup \(P\) defined over \(Q\), there exists a connected reductive algebraic subgroup \(M\) of \(P\) defined over \(Q\) without nontrivial \(\mathbb{Q}\)-characters such that \(AM\) is the centraliser of \(A\) in \(G\). In particular, \(AM\) is a Levi subgroup of \(P\) defined over \(Q\), \(A\) centralises \(M\) and is the largest \(\mathbb{Q}\)-split subtorus of the centre of \(AM\), \(AM\) normalises \(U\), and
\[
P = AMU.
\]
For every Lie group \(G'\) endowed with a left Haar measure, for every discrete subgroup \(\Gamma'\) of \(G'\), we endow \(\Gamma' \backslash G'\) with the unique measure such that the canonical covering map \(G' \rightarrow \Gamma' \backslash G'\) locally preserves the measures.

In what follows, we will need a normalisation of the Haar measures, which behaves appropriately when passing to some subgroups. We will start with a Riemannian metric on \(G(\mathbb{R})\), take the induced Riemannian volumes on the real points of the various algebraic subgroups of \(G\) defined over \(Q\) that will appear, which will give us the choices necessary for using Weil's normalisation to define the Siegel weights.

The main result of this paper is the following one.

**Theorem 5** Let \(G\) be a connected reductive linear algebraic group defined over \(Q\), without nontrivial \(\mathbb{Q}\)-characters. Let \(G = G(\mathbb{R})_0\) and \(\Gamma = G(\mathbb{Z}) \cap G\). Let \(P\) be a parabolic subgroup of \(G\) defined over \(Q\), and let \(P = AMU\) be a relative Langlands decomposition of \(P\). Let \(\rho : G \rightarrow GL(V)\) be a rational representation of \(G\) defined over \(Q\) such that there exists \(v_0 \in V(Q)\) whose stabiliser in \(G\) is \(H = MU\). Let \(L\) be a reductive algebraic subgroup of \(G\) defined and anisotropic over \(Q\).

Assume that \(LP\) is Zariski-open in \(G\) and that for every \(a \in A\), the orbit \(\rho(La)v_0\) is Zariski-closed in \(V\). Endow \(G(\mathbb{R})\) with a left-invariant Riemannian metric, for which the Lie algebras of \(H(\mathbb{R})\) and \(A(\mathbb{R})\) are orthogonal, and the orthogonal of the Lie algebra of \(P(\mathbb{R})\) is contained in the Lie algebra of \(L(\mathbb{R})\).

Then there exists \(\delta > 0\) such that, as \(T = (t_\alpha)_{\alpha \in \Delta - I} \in [0, +\infty)^{\Delta - I}\) and \(\min_{\alpha \in \Delta - I} t_\alpha\) tends to \(+\infty\),
\[
\sum_{a \in A_T} \left| \frac{1}{|L|} \int_{L(\mathbb{R})} w'_L, \rho_L(x) \right| \frac{\text{vol}((H \cap \Gamma) \backslash (H \cap G)) \text{vol}(\Lambda^\vee \backslash A(\mathbb{R})_0)}{\text{vol}(\Gamma \backslash G)} \left( \prod_{\alpha \in \Delta - I} e^{\frac{m_\alpha t_\alpha}{m_\alpha}} (1 + O(e^{-\delta \min_{\alpha \in \Delta - I} t_\alpha})) \right).
\]
Proof. Let us start by fixing the notation that will be used throughout the proof of Theorem 5, and by making more explicit the above-mentioned conventions about the various volumes that occur in the asymptotic formula.

Consider the connected real Lie group $G = G(\mathbb{R})_0$, its (closed) Lie subgroups

$$A = A(\mathbb{R})_0, \quad H = H \cap G, \quad L = L(\mathbb{R})_0, \quad M = M \cap G, \quad P = P \cap G, \quad U = U(\mathbb{R})_0.$$  

We have $H = MU$ and $P = AMU = MA$, since $A$ and $U$ are connected. Note that $L$ is also connected, but $H$ and $M$ are not necessarily connected. We denote by

$$a,\ g,\ h,\ l,\ m,\ p,\ u$$

the Lie algebras of the real Lie groups $A,G,H,L,M,P,U$ respectively, endowed with the restriction of the scalar product on $g$ defined by the Riemannian metric of $G$. Since $L$ is $\mathbb{Q}$-anisotropic, so is $L \cap P$. Since the map $L \cap P \to P/H \simeq A$ is defined over $\mathbb{Q}$ and $A$ is a $\mathbb{Q}$-split torus, this implies that the identity component of $L \cap P$ is contained in $H$. In particular

$$I \cap h = I \cap p.$$  

(3)

Note that $g = l + p$ since $LP$ is Zariski-open in $G$. We have assumed that $a$ is orthogonal to $h$ and that the orthogonal $p^\perp$ of $p$ is contained in $l$. In particular, with $q$ the orthogonal of $l \cap h$ in $h$, we have the following orthogonal decompositions

$$g = p^\perp \oplus (l \cap h) \oplus q \oplus a, \quad h = (l \cap h) \oplus q, \quad l = p^\perp \oplus (l \cap h), \quad p = h \oplus a.$$  

(4)

The left-invariant Riemannian metric on $G$ induces a left Haar measure $\omega_G$ on $G$, and a left-invariant Riemannian metric on every Lie subgroup $G'$ of $G$, hence a left Haar measure $\omega_{G'}$ on $G'$ (which is the counting measure if $G'$ is discrete). Note that $A,G,H,L,M,U,L \cap H$ are unimodular: indeed $A,G,L,M$ are reductive and $U$ is unipotent; furthermore, $L \cap H$ is the stabiliser of $v_0$ in $L$, the orbit of $v_0$ under $L$ is affine and hence $L \cap H$ is reductive by [BHC, Theo. 3.5]. But $P$ is not unimodular.

The map $A \times M \times U \to P$ defined by $(a,m,u) \mapsto amu$ is a smooth diffeomorphism (see for instance [BJ, page 273]). We will denote by $d\omega_A d\omega_H$ the measure on $P$ which is the push-forward of the product measure by the diffeomorphism $(a,h) \mapsto ah$. Since $A$ normalises $H$, the measure $d\omega_A d\omega_H$ is left-invariant by $P$, so that $d\omega_P(ah)$ and $d\omega_A(a)d\omega_H(h)$ are proportional. Since these measures are induced by Riemannian metrics, and since $a$ and $h$ are orthogonal, we hence have

$$d\omega_P(ah) = d\omega_A(a)d\omega_H(h).$$

Since $A$ normalises $U$, the group $A$ acts on the Lie algebra $\mathfrak{u}$ of $U$ by the adjoint representation. The roots of this linear representation of $A$ are exactly the restrictions to $A$ of the elements $\beta$ in $\Phi^C_+ - \Phi^F_+$, with root spaces $\mathfrak{g}^C_+ \cap \mathfrak{g}$ and a set of simple roots is the set of restrictions of the elements of $\Delta - I$ to $A$ (see for instance [BJ, Rem. III.1.14]). Since $A$ is connected, these roots have value in $]0,\infty[$. The map $A \to \mathbb{R}^{\Delta - I}$ defined by $a \mapsto (\log(\alpha(a)))_{\alpha \in \Delta - I}$ is hence a smooth diffeomorphism. We will denote by $\prod_{\alpha \in \Delta - I} dt_{\alpha}$
the measure on \( A \) which is the push-forward of the product Lebesgue measure by the inverse of this diffeomorphism. By invariance, there exists a constant \( c_A > 0 \) such that

\[
d\omega_A = c_A \prod_{\alpha \in \Delta - I} dt_{\alpha}.
\]

By the definition of \( \Lambda' \), we have \( c_A = \text{Vol}(\Lambda' \setminus A) \).

Let \( \Gamma = G(\mathbb{Z}) \cap G \), which is a discrete subgroup of \( G \) acting isometrically for the Riemannian metric of \( G \) by left translations. Let \( Y_G = \Gamma \setminus \Gamma \) and let \( \pi : G \to Y_G = \Gamma \setminus G \) be the canonical projection, which is equivariant under the right actions of \( G \). Then \( Y_G \) is a connected Riemannian manifold (for the unique Riemannian metric such that \( \pi \) is a local isometry) endowed with the transitive right action of \( G \) by translations on the right.

To simplify the notation, for every Lie subgroup \( G' \) of \( G \), define

\[
Y_{G'} = \pi(G'),
\]

which is a injectively immersed submanifold in \( Y_G \), endowed with the Riemannian metric induced by \( Y_G \), and identified with \( (G' \cap \Gamma) \setminus G' \) by the map induced by the inclusion of \( G' \) in \( G \). Note that \( Y_L \) and \( Y_U \) are connected, but \( Y_H \) and \( Y_M \) are not necessarily connected.

For every Lie subgroup \( G' \) of \( G \), let

\[
\mu_{G'}
\]

be the Riemannian measure on \( Y_{G'} \), which locally is the push-forward of the left Haar measure \( \omega_{G'} \).

Since \( G \) and the identity component of \( \textbf{MU} \) have no nontrivial \( \mathbb{Q} \)-character, the Riemannian manifolds \( Y_G \) and \( Y_H \) have finite volume (see [BHC, Theo. 9.4]) and \( Y_H \) is closed in \( Y_G \) (see for instance [Rag, Theo. 1.13]). Since \( L \) is reductive and \( \mathbb{Q} \)-anisotropic, the submanifold \( Y_L \) is compact (see [BHC, Theo. 11.6]). Since \( U \) is unipotent, the submanifold \( Y_U \) is compact (see for instance [BHC, § 6.10]).

For every Lie subgroup \( G' \) of \( G \) such that \( Y_{G'} \) has finite measure (that is, such that \( \Gamma \cap G' \) is a lattice in \( G' \)), we denote by

\[
\overline{\mu}_{G'} = \frac{\mu_{G'}}{\|\mu_{G'}\|}
\]

the finite measure \( \mu_{G'} \) normalised to be a probability measure. In particular, \( \overline{\mu}_G, \overline{\mu}_H, \overline{\mu}_L, \overline{\mu}_U \) are well defined.

For every \( T = (t_{\alpha})_{\alpha \in \Delta - I} \) and \( T' = (t'_{\alpha})_{\alpha \in \Delta - I} \) in \( [0, +\infty)^{\Delta - I} \), let

\[
A_{[T,T']} = \{a \in A : \forall \alpha \in \Delta - I, \ t_{\alpha} \leq \log(\alpha(a)) \leq t'_{\alpha} \}.
\]

and \( P_{[T,T']} = UMA_{[T,T']}^{-1} = HA_{[T,T']}^{-1} \). Define \( Y_{P_{[T,T']}} = \pi(P_{[T,T']}) \), which is a submanifold with boundary of \( Y_G \), invariant under the right action of \( H \), since \( A \) normalises \( H \).

To shorten the notation, we define

\[
A_T = A_{[0,T]}, \quad P_T = P_{[0,T]} = HA_T^{-1} \quad \text{and} \quad Y_{P_T} = Y_{P_{[0,T]}} = \pi(P_T) = Y_H A_T^{-1},
\]

as well as \( \min T = \min_{\alpha \in \Delta - I} t_{\alpha} \geq 0 \), which measures the complexity of \( T \) and will converge to \( +\infty \). We will need to estimate the volume of \( \pi(P_T) \) for \( \mu_P \).
Lemma 6 For every $T = (t_α)_{α ∈ Δ-I}$ in $[0, +∞[^{Δ-I}$, we have

$$\mu_P(Y_{P_r}) = \vol(A^V \setminus A(ℝ)_0) \frac{||µ_H||}{m_α} \prod_{α ∈ Δ-I} e^{m_α t_α}.$$ 

Proof. Denote by $du_β$ the Lebesgue measure on the Euclidean space $g_β = g_β^C ∩ g$. For any order on $Φ^C_+ - Φ^F_+$, the map from $\prod_{β ∈ Φ^C_+ - Φ^F_+} g_β$ to $U$ defined by $(u_β)_{β ∈ Φ^C_+ - Φ^F_+} → \prod_{β ∈ Φ^C_+ - Φ^F_+} exp u_β$ is a smooth diffeomorphism, and there exists $c_U > 0$ such that $dω_U$ is the push-forward by this diffeomorphism of the measure $c_U \prod_{β ∈ Φ^C_+ - Φ^F_+} du_β$.

For every $a ∈ A$, if $i_a : g → a ga^{-1}$ is the conjugation by $a$, then for every $u_β ∈ g_β$, we have $i_a(exp u_β) = exp((Ad a)(u_β)) = exp(β(a) u_β)$. Hence

$$(i^{-1}_a)_*(ω_U) = \prod_{β ∈ Φ^C_+ - Φ^F_+} β(α)^{dim g_β} ω_U = \prod_{α ∈ Δ-I} α(α)^{m_α} ω_U$$

by the definition of $(m_α)_{α ∈ Δ}$ and since the elements of $I$ are trivial on $A$. Since $A$ commutes with $M$, we hence have $(i^{-1}_a)_*(ω_U) = \prod_{α ∈ Δ-I} α(α)^{m_α} ω_H$.

We have, since $A$ is unimodular,

$$dω_P(ha^{-1}) = dω_P(a^{-1}aha^{-1}) = dω_A(a^{-1}) dω_H(aha^{-1}) = dω_A(a) d((i^{-1}_a)_*(ω_H))(h).$$

Since $Γ \cap P = Γ \cap H$ (see for instance the lines following Proposition III.2.21 in [BJ, page 285]) and $A \cap H = \{e\}$, we have $π(Ha) ≠ π(Ha')$ if $a ≠ a'$. Hence

$$\mu_P(Y_{P_r}) = \int_{y ∈ Y_H} \int_{a ∈ A_r} \mu_P(ya^{-1}) = \int_{A_r} \prod_{α ∈ Δ-I} α(α)^{m_α} dω_A(a) \int_{Y_H} dµ_H$$

$$= ||µ_H|| c_A \prod_{α ∈ Δ-I} \int_0^{t_α} e^{m_α s} ds.$$ 

Since $m_α > 0$, the result follows.

To simplify the notation, we write $ρ(g)x = gx$ for every $g ∈ G$ and $x ∈ V$, we define $v_α = av_0$ for every $a ∈ A$, and we denote by $L_x = G_x ∩ L$ the stabiliser of $x$ in $L$ for every $x ∈ V(ℝ)$.

Since we have a left Haar measure $ω_L$ on $L$ and $ω_{L ∩ H}$ on $L ∩ H$, Weil’s normalisation gives a $L$-invariant measure on the homogeneous space $L/(L ∩ H)$, and hence a left Haar measure on the stabilisers $ℓ((L ∩ H)/L)$ for every $ℓ$ in $L$, as explained above. As announced, the modified Siegel weights $w'_{L, ρ, L}(·)$ are defined using this Weil’s normalisation, as follows.

For every $ℓ ∈ L$ and $a ∈ A$, if $x = ℓav_0$, since $H = MU$ is normalised by $A$ and is the stabiliser of $v_0$ in $G$, we have

$$L_x = L ∩ Stab_G x = L ∩ (ℓHℓ^{-1}) = ℓ(L ∩ H)ℓ^{-1}.$$ 

Note that

$$L(ℝ)_0 ∩ L(Z) = L(ℝ)_0 ∩ G(Z) = L(ℝ)_0 ∩ G(ℝ)_0 ∩ G(Z) = L ∩ Γ,$$

and similarly $L(ℝ)_0 ∩ L_x(Z) = L_x ∩ Γ$ for every $x ∈ L v_α ∩ Γ v_α$. Hence the denominator of the modified Siegel weight $w'_{L, ρ, L}(x)$ is equal to $vol((L ∩ Γ)/L) = vol(Y_L)$, using the
measure \(\mu_L\) on \(Y_L\) induced by the Haar measure \(\omega_L\) on \(L\). Its numerator \(\text{vol}((L_x \cap \Gamma)\setminus L_x)\) is defined by using the measure on \((L_x \cap \Gamma)\setminus L_x\) induced by the left Haar measure on \(L_x = \ell(L \cap H)\ell^{-1}\) given by Weil’s normalisation.

We now proceed to the proof of Theorem 5.

**Step 1.** The first step of the proof is the following group theoretic lemma, which relates the counting function of modified Siegel weights to the counting function of volumes of orbits of \(L \cap H\). We denote with square brackets the (left or right) appropriate orbit of an element.

**Lemma 7** For every \(a \in A\), there exists a bijection between finite subsets

\[
\Theta_a : (L \cap \Gamma)\setminus(Lv_a \cap \Gamma \gamma_0) \rightarrow (L \cap Y_H a^{-1})/(L \cap H)
\]

such that for every \(x \in Lv_a \cap \Gamma \gamma_0\), if \([y] = \Theta_a([x])\), then

\[
\text{vol}((L_x \cap \Gamma)\setminus L_x) = \text{vol} \left( \frac{y(L \cap H)}{\text{vol}(Y_L)} \right).
\]

(8)

In particular, for every \(T \in [0, +\infty[^{d-1}\), we have

\[
\sum_{a \in A_T} \sum_{[x] \in (L \cap \Gamma)\setminus(Lv_a \cap \Gamma \gamma_0)} w'_{L \cap H}(x) = \sum_{a \in A_T} \sum_{[y] \in (L \cap Y_H a^{-1})/(L \cap H)} \text{vol} \left( \frac{y(L \cap H)}{\text{vol}(Y_L)} \right).
\]

**Proof.** Fix \(a \in A\). First note that the groups \(L \cap \Gamma\) and \(L \cap H\) do preserve the subsets \(Lv_a \cap \Gamma \gamma_0\) of \(V(\mathbb{R})\) and \(Y_L \cap Y_H a^{-1}\) of \(Y\) respectively for their left and right action, since \(A\) normalises \(H\). The finiteness of the set \((L \cap \Gamma)\setminus(Lv_a \cap \Gamma \gamma_0)\) follows from Borel-Harish-Chandra’s finiteness theorem as in the introduction. Also recall that \(H = MU\) is the stabiliser of \(\gamma_0\) in \(G\).

Define

\[
\Theta_a : [\ell v_a] \mapsto [\pi(\ell)].
\]

Let us prove that this map is well defined and bijective. Let \(\ell, \ell' \in L\).

We have \(\ell v_a \in \Gamma \gamma_0\) if and only if there exists \(\gamma \in \Gamma\) such that \(\ell a v_0 = \gamma v_0\), that is, if and only if there exist \(\gamma \in \Gamma\) and \(h \in H\) such that \(\ell = \gamma ha^{-1}\), that is, if and only if \(\pi(\ell) \in Y_L \cap Y_H a^{-1}\). This proves that \(\Theta_a\) has values in \((Y_L \cap Y_H a^{-1})/(L \cap H)\) and is surjective.

Let us prove that \(\Theta_a\) does not depend on the choice of representatives and is injective. We have \([\ell' v_a] = [\ell v_a]\) if and only if there exists \(\gamma \in L \cap \Gamma\) such that \(\ell' a v_0 = \gamma a v_0\), hence if and only if there exist \(\gamma \in L \cap \Gamma\) and \(h \in H\) such that \(\ell' a = \gamma a h\). Note that this equation implies that \(aha^{-1} \in L\) if and only if \(\gamma \in L\). Since \(A\) normalises \(H\), we hence have \([\ell' v_a] = [\ell v_a]\) if and only if \(\ell' \in \Gamma \ell(L \cap H)\), that is if and only if \([\pi(\ell)] = [\pi(\ell')].\)

To prove the second assertion, let \(\ell \in L\) be such that \(x = \ell v_a \in \Gamma \gamma_0\) and let \(y = \pi(\ell)\), so that \(\Theta_a([x]) = [y]\). The orbit of \(y\) under \(L \cap H\) in \(Y_L\) is the image by the locally isometric map \(\pi\) of the Riemannian submanifold \(\ell(L \cap H)\) of \(G\). The left translation by \(\ell^{-1}\) is an isometry (hence is volume preserving) from \(\ell(L \cap H)\) to \((L \cap H)\). By Lemma 4, the map \(g \mapsto \ell g\ell^{-1}\) from \(L \cap H\) to \(\ell(L \cap H)\ell^{-1}\), which is equal to \(L_x\) by Equation (6), is measure preserving. Therefore the map \(\varphi : [z] \mapsto [\ell z]\) from \((L_x \cap \Gamma)\setminus L_x\) to \(y(L \cap H)\) is a measure preserving bijection. This proves the volume equality of Equation (8).
The last claim follows from the other ones, since the numerator of the modified Siegel weight \( w_{L',\rho,L}^\prime(x) \) is \( \text{vol} \left( (L_x \cap \Gamma) \setminus L_x \right) \).

\[ \square \]

**Step 2.** The second step of the proof is an equidistribution result, in the spirit of [KM1], saying that the piece \( Y_{P_T} \) of orbit of \( P \) equidistributes in \( Y_G \) as \( \min T \to +\infty \).

For every smooth Riemannian manifold \( Z \) and \( q \in \mathbb{N} \), we denote by \( C^q_c(Z) \) the normed vector space of \( C^q \) maps with compact support on \( Z \), with norm \( \| \cdot \|_q \).

**Proposition 8** There exist \( q \in \mathbb{N} \) and \( \kappa > 0 \) such that for every \( f \in C^q_c(Y_G) \) and \( T = (t_a)_{a \in \Delta - I} \in [0, +\infty[^{\Delta - I} \), we have, as \( \min T \) tends to \( +\infty \),

\[
\frac{1}{\mu_P(Y_{P_T})} \int_{Y_{P_T}} f \, d\mu_P = \int_{Y_G} f \, d\mu_G + O \left( e^{-\kappa \min T \| f \|_q} \right).
\]

To prove the proposition, we will use the disintegration formula already seen in the proof of Lemma 6

\[
\int_{Y_{P_T}} f \, d\mu_P = \int_{A_T} \left( \int_{Y_H} f(ya^{-1}) \, d\mu_H(y) \right) \left( \prod_{a \in \Delta - I} \alpha(a)^{m_a} \right) d\omega_A(a).
\]

This formula indicates that the proposition would follow from (an averaging of) the equidistribution of the translates \( Y_H a^{-1} \), which is established in Proposition 9 below. To state this proposition, we need to introduce additional notation.

The linear algebraic group \( G \) decomposes as an almost direct product

\[ G = Z(G)G_1 \cdots G_s \]

where \( Z(G) \) is the centre of \( G \), and \( G_1, \ldots, G_s \) are \( \mathbb{Q} \)-simple connected algebraic subgroups of \( G \). The maximal \( \mathbb{Q} \)-split torus \( S \) decomposes as an almost direct product

\[ S = S_1 \cdots S_s \]

where \( S_i \) is a maximal \( \mathbb{Q} \)-split torus in \( G_i \). We also get an almost direct product decomposition

\[ G = Z(G)G_1 \cdots G_s, \quad (9) \]

where \( Z(G) \) is the centre of \( G \) (which is equal to \( Z(G)_0 \) since \( G \) is connected and \( G \) is Zariski-dense in \( G \)) and \( G_i = G_i(\mathbb{R})_0 \) for \( 1 \leq i \leq s \). Since \( G \) has no nontrivial \( \mathbb{Q} \)-character, and since \( M \) is the centraliser of \( A \), this gives corresponding almost direct product decompositions of the Lie groups \( A = A_1 \cdots A_s \) (this one being a direct product), \( U = U_1 \cdots U_s \), \( M = Z(G)M_1 \cdots M_s \), \( H = Z(G)H_1 \cdots H_s \). The set of simple roots \( \Delta \) decomposes as a disjoint union

\[ \Delta = \Delta_1 \sqcup \cdots \sqcup \Delta_s \]

where \( \Delta_i \) is a set of simple roots of \( G_i \) relatively to \( S_i \), and the positive (closed) Weyl chamber \( A^+ \) in \( A \) associated to \( \Delta \) decomposes as

\[ A^+ = A_1^+ \cdots A_s^+, \]

where \( A_i^+ \) is the positive (closed) Weyl chamber in \( A \cap G_i \) associated to \( \Delta_i \).
For $1 \leq i \leq s$ and $a \in A_i$, we define
\[ E_i(a) = \exp \left( - \left( \max_{\alpha \in \Delta_i - I} \log \alpha(a) \right) \right) > 0 \] (10)
if $\Delta_i - I \neq \emptyset$, and $E_i(a) = 0$, otherwise. For every $\kappa > 0$, we also define
\[ E^\kappa(a) = \sum_{i=1}^{s} E_i(a_i)^\kappa \]
for every $a \in A^+$ with $a_1 \in A_1^+, \ldots, a_s \in A_s^+$ and $a = a_1 \cdots a_s$.

**Proposition 9** There exist $q \in \mathbb{N}$ and $\kappa > 0$ such that for all $f \in C^0_c(Y_G)$ and $a \in A^+$,
\[ \int_{Y_H} f(ya^{-1}) d\bar{\nu}_H(y) = \int_{Y_G} f \, d\bar{\nu}_G + O \left( E^\kappa(a) \|f\|_q \right). \]

Given a Lie subgroup $D$ of $G$ such that $\Gamma \cap D$ is a lattice in $D$, we denote by $\nu_D$ the normalised right invariant measure on $(\Gamma \cap D) \backslash D$. Recall that $Y_D = \pi(D)$ is a closed submanifold of $Y_G$, and that $\mu_D$ is the invariant measure on $Y_D$ induced by the Riemannian metric, with normalised measure $\bar{\nu}_D$.

We identify $(\Gamma \cap H) \backslash H$ with $Y_H$ using the (well defined) map $h \mapsto \Gamma h$ (denoting again by $h \in H$ a representative of a coset $h \in (\Gamma \cap H) \backslash H$). Since the groups $Z(G), H_1, \ldots, H_s$ commute, we also have the map
\[ (\Gamma \cap Z(G)) \backslash Z(G) \times (\Gamma \cap H_1) \backslash H_1 \times \cdots \times (\Gamma \cap H_s) \backslash H_s \to Y_H \]
well defined by $(h_0, h_1, \ldots, h_s) \mapsto \Gamma h_0 h_1 \cdots h_s$ (using conventions similar to the above one for coset representatives). Then the normalised invariant measures $\bar{\nu}_H, \bar{\nu}_{H_1}, \ldots, \bar{\nu}_{H_s}$ satisfy, for all $f \in C^0_c(Y_G),$
\[ \int_{Y_H} f(y) \, d\bar{\nu}_H(y) = \int_{(\Gamma \cap H) \backslash H} f(\Gamma h) \, d\bar{\nu}_H(h) \\
= \int_{(\Gamma \cap Z(G)) \backslash Z(G) \times \cdots \times (\Gamma \cap H_s) \backslash H_s} f(\Gamma h_0 h_1 \cdots h_s) \, d\bar{\nu}_{Z(G)}(h_0) \cdots d\bar{\nu}_{H_s}(h_s). \] (11)

We will prove Proposition 9 by using an inductive argument on the number of factors. We start by analysing the distribution of $Y_{U_i} a^{-1}$ in Lemma 10 and then the distribution of $Y_{H_i} a^{-1}$ in Lemma 11.

Let $D$ be a product of almost direct factors of $G$ in the decomposition (9). For every $f \in C^0_c(Y_G)$, we define a map $\mathcal{P}_D f : Y_G \to \mathbb{C}$ by
\[ (\mathcal{P}_D f)(\Gamma g) = \int_{(\Gamma \cap D) \backslash D} f(\Gamma dg) \, d\bar{\nu}_D(d) \]
which does not depend on the choice of the representative of $\Gamma g$, by the right invariance of $\nu_D$ under $D$. Note that $\mathcal{P}_D f$ is continuous and invariant under the right action of $D$.

**Lemma 10** There exist $q \in \mathbb{N}$ and $\kappa_1 > 0$ such that for every $i \in \{1, \ldots, s\}$ with $A_i \neq \{1\}$, for every $f \in C^0_c(Y_G)$ and $a \in A_i^+$,
\[ \int_{Y_{U_i}} f(ya^{-1}) \, d\bar{\nu}_{U_i}(y) = (\mathcal{P}_G f)(\Gamma e) + O \left( E_i(a)^{\kappa_1} \|f\|_{Y_{U_i}} \|q\) . \]
Proof. For $1 \leq i \leq s$, we consider the unitary representation of the group $G_i$ on the orthogonal complement of the space of $G_i$-invariant (hence constant on $Y_{G_i}$) functions in the Hilbert space $L^2(Y_{G_i}, \overline{\mu}_{G_i})$, whose scalar product we denote by $\langle \cdot, \cdot \rangle_{Y_{G_i}}$ (using the normalised measure $\overline{\mu}_{G_i}$). We note that for every $f \in \mathcal{C}_c(Y_{G_i})$, the function $f|_{Y_{G_i}} - (\mathcal{P}_{G_i} f)(\Gamma e)$ belongs to this space.

We say that a unitary representation of a connected real semisimple Lie group $G'$ has the strong spectral gap property if the restriction to every noncompact simple factor of $G'$ is isolated from the trivial representation for the Fell topology (see for instance [Cow], [BdlHV, Appendix], [KM2, Appendix] for equivalent definitions and examples, and compare for instance with [Nev, KS] for variations on the terminology). We claim that the above unitary representation of $G_i$ has the strong spectral gap property. Indeed, if $G_i$ is simply connected, the strong spectral gap property on $\Gamma_i \setminus G_i$ is a direct consequence of the property $\tau$ proved in [Clo], see Theorem 3.1 therein. By [KM2, Lemma 3.1], this also implies, when $G_i$ is simply connected, the strong spectral property on $\Gamma_i \setminus G_i$ for subgroups $\Gamma_i$ that are commensurable with congruence subgroups, and, in particular, for arithmetic subgroups of $G_i$. Now let $p_i : G_i \to G_i$ be a simply connected cover of $G_i$, and let $\tilde{G}_i = G_i(\mathbb{R})$. Then $Y_{\tilde{G}_i} \simeq p_i^{-1}(\Gamma \cap G_i) \setminus \tilde{G}_i$, and the strong spectral gap property for $L^2(Y_{\tilde{G}_i}, \overline{\mu}_{\tilde{G}_i})$ follows from the above arguments.

Applying [KM1, Theorem 2.4.3], we deduce that there exist $q \in \mathbb{N}$ and $\kappa'_i > 0$ such that for every $i \in \{1, \ldots, s\}$ such that $A_i \neq \{e\}$, for every $\phi \in \mathcal{C}_c^q(Y_{G_i})$ and $a \in A_i^+$,

$$\tag{12} \langle (f|_{Y_{G_i}} - (\mathcal{P}_{G_i} f)(\Gamma e)) \circ a^{-1}, \phi \rangle_{Y_{G_i}} \leq C E_i(a)^{\kappa'_i} \|f|_{Y_{G_i}}\|_q \|\phi\|_q,$$

where $E_i(a)$ is defined in Equation (10).

Let $P_i^-$ denote the parabolic subgroup in $G_i$ opposite to $U_i$. The product map $U_i \times P_i^- \to G_i$ is a diffeomorphism between neighbourhoods of the identities. Since $Y_{U_i} = \pi(U_i)$ is compact, if $\epsilon > 0$ is small enough, there exists an open $\epsilon$-neighbourhood $\Omega_\epsilon$ of the identity in $P_i^-$ such that the product map $Y_{U_i} \times \Omega_\epsilon \to Y_{G_i}$ is a diffeomorphism onto its image $Y_{U_i} \Omega_\epsilon$. We have (see also Lemma 13)

$$\forall y \in Y_{U_i}, \forall \rho \in \Omega_\epsilon, \quad a\overline{\mu}_{G_i}(yp) = a\overline{\mu}_{U_i}(y) d\omega(p),$$

for a suitably normalised smooth measure $\omega$ on $\Omega_\epsilon$. There exists $\sigma > 0$ (depending on $q$) such that for every $\epsilon > 0$ small enough, there exists a nonnegative function $\psi_\epsilon \in \mathcal{C}_c^q(\Omega_\epsilon)$ satisfying

$$\int_{\Omega_\epsilon} \psi_\epsilon d\omega = 1 \quad \text{and} \quad \|\psi_\epsilon\|_q = O(\epsilon^{-\sigma}).$$

Define a $C^q$ function $\phi_\epsilon : Y_{G_i} \to [0, +\infty]$ supported on $Y_{U_i} \Omega_\epsilon$ by

$$\forall y \in Y_{U_i}, \forall \rho \in \Omega_\epsilon, \quad \phi_\epsilon(yp) = \psi_\epsilon(p).$$

Then

$$\int_{Y_{G_i}} \phi_\epsilon d\overline{\mu}_{G_i} = 1 \quad \text{and} \quad \|\phi_\epsilon\|_q = O(\epsilon^{-\sigma}).$$

Since for all $a \in A_i^+$ and $\rho \in \Omega_\epsilon$,

$$d(a\rho a^{-1}, \epsilon) = O(\epsilon),$$

13
we obtain
\[
\langle f|_{Y_{G_i}} \circ a^{-1}, \phi_e \rangle_{Y_{G_i}} = \int_{Y_{G_i} \times \Omega} f(ypa^{-1}) \psi_e(p) \, d\overline{m}_{U_i}(y) \, d\omega(p) \\
= \int_{Y_{H_i}} f(ya^{-1}) \, d\overline{m}_{U_i}(y) + O \left( \epsilon \| f|_{Y_{G_i}} \|_1 \right).
\]

Since $\mathcal{P}_G, f$ is $G_i$-invariant,
\[
\langle \mathcal{P}_G, f, \phi_e \rangle_{Y_{G_i}} = (\mathcal{P}_G, f)(\Gamma e) \left( \int_{Y_{G_i}} \phi_e \, d\overline{m}_{G_i} \right) = (\mathcal{P}_G, f)(\Gamma e).
\]
Combining these estimates with (12) (we may assume that $q \geq 1$), we conclude that
\[
\int_{Y_{H_i}} f(ya^{-1}) \, d\overline{m}_{H_i}(y) = (\mathcal{P}_G, f)(\Gamma e) + O \left( (\epsilon + E_i (a)^{\kappa_i} \epsilon^{-\sigma}) \| f|_{Y_{G_i}} \|_q \right).
\]
Finally, taking $\epsilon = E_i (a)^{\kappa_i/(1+\sigma)}$ which is small if $a$ lies outside a compact subset of $A_i^+$, we deduce that
\[
\int_{Y_{H_i}} f(ya^{-1}) \, d\overline{m}_{H_i}(y) = (\mathcal{P}_G, f)(\Gamma e) + O \left( E_i (a)^{\kappa_i/(1+\sigma)} \| f|_{Y_{G_i}} \|_q \right),
\]
as required. □

**Lemma 11** There exist $q \in \mathbb{N}$ and $\kappa_2 > 0$ such that for every $f \in \mathcal{C}_c^2(Y_G)$ and $a \in A_i^+$, for every $i \in \{1, \ldots, s\}$, we have
\[
\int_{Y_{H_i}} f(ya^{-1}) \, d\overline{m}_{H_i}(y) = (\mathcal{P}_G, f)(\Gamma e) + O \left( E_i (a)^{\kappa_2} \| f|_{Y_{G_i}} \|_q \right).
\]

**Proof.** We first observe that if $A_i = \{e\}$, then $H_i = G_i$, and the claim of the lemma is obvious. Now we assume that $A_i \neq \{e\}$ in which case Lemma 10 applies.

Let $N_i = (\Gamma \cap M_i) \backslash M_i$. The space $Y_{H_i} = \pi(U_i M_i)$ is a bundle over $N_i$ with fibres isomorphic to $Y_{U_i}$, and the invariant measure $\overline{m}_{H_i}$ on $Y_{H_i}$ decomposes with respect to this structure. Explicitly, for every $m \in M_i$, the integrals $\int_{Y_{U_i}} f(y(m)) \, d\overline{m}_{U_i}(y)$ for all $f \in \mathcal{C}_c(Y_G)$ define a $U_i$-invariant probability measure on $Y_{U_i} m$, which depends only on the coset $n = [m]$ of $m$ in $N_i = (\Gamma \cap M_i) \backslash M_i$, and the $H_i$-invariant probability measure on $Y_{H_i}$ is given by $\int_{N_i} \left( \int_{Y_{U_i}} f(y(m)) \, d\overline{m}_{U_i}(y) \right) \, d\overline{m}_{M_i}([m])$ for all $f \in \mathcal{C}_c(Y_G)$. Hence, denoting again by $n$ any representative of a coset $n$ in $N_i$, since $A$ centralises $M$,
\[
\int_{Y_{H_i}} f(ya^{-1}) \, d\overline{m}_{H_i}(y) = \int_{N_i} \int_{Y_{U_i}} f(y(na^{-1}) \, d\overline{m}_{U_i}(y) \, d\overline{m}_{M_i}(n) \\
= \int_{N_i} \int_{Y_{U_i}} f(ya^{-1}n) \, d\overline{m}_{U_i}(y) \, d\overline{m}_{M_i}(n).
\]

For $m \in M_i$ and $f \in \mathcal{C}_c(Y_G)$, we consider the function $f_m : Y_G \to \mathbb{C}$ defined by $y \mapsto f(y(m))$. We note that there exist $c_1, C' > 0$ such that for every $f \in \mathcal{C}_c^2(Y_G)$, we have
\[
\| f_m|_{Y_{G_i}} \|_q \leq C' c_1 a^{d(e, m)} \| f|_{Y_{G_i}} \|_q.
\]
Hence, by Lemma 10, for every \( f \in C_c^0(Y_{\Gamma}) \) and \( m \in M_i \), since \( \mathcal{P}_{G_i}f_m = \mathcal{P}_Gf \) by invariance under \( G_i \),

\[
\int_{Y_{U_i}} f(y a^{-1} m) \, d\mu_{U_i}(y) = (\mathcal{P}_G, f)(\Gamma e) + O \left( E_i(a)^{\kappa_1} e^{c_1 d(e, m)} \| f \|_{Y_{\Gamma_i}} \| q \right).
\]  

We fix \( n_0 \in N_i \) and for \( R > 0 \), we set

\[
(N_i)_R = \{ n \in N_i : d(n_0, n) \leq R \},
\]

where \( d(\cdot, \cdot) \) denotes the distance on \( N_i \) with respect to the induced Riemannian metric.

To prove this estimate, we may pass to an equivalent Riemannian metric and to a finite index subgroup of \( \Gamma \cap M_i \). This way, we reduce the proof to the case when \( M_i \) is semisimple, \( \Gamma \) is a lattice in \( M_i \), and the Riemannian metric on \( M_i \) is bi-invariant under a maximal compact subgroup in \( M_i \). Then Equation (14) follows from [KM2, §5.1]

Equation (14) implies that

\[
\int_{N_i - (N_i)_R} \int_{Y_{U_i}} f(y a^{-1} n) \, d\mu_{U_i}(y) \, d\nu_M(n) = O \left( e^{-c_2 R} \| f \|_{Y_{\Gamma_i}} \| q \right).
\]  

Finally, combining (15) and (16), we obtain that

\[
\int_{N_i} \int_{Y_{U_i}} f(y a^{-1} n) \, d\mu_{U_i}(y) \, d\nu_M(n) = (\mathcal{P}_G, f)(\Gamma e) + O \left( E_i(a)^{\kappa_1} e^{c_1 R} \| f \|_{Y_{\Gamma_i}} \| q \right).
\]  

Taking \( R = \log E_i(a)^{-\frac{\kappa_2}{c_1 + c_2}} \), we deduce the claim of Lemma 11 with \( \kappa_2 = \frac{k \log a}{c_1 + c_2} \).

**Proof of Proposition 9.** For a subsemigroup \( D \) which decomposes as a product \( D = D_{\leq i} \cdots D_{q} \) and \( p \leq i \leq q \), we write

\[
D_{\leq i} = D_p \cdots D_i \quad \text{and} \quad D_{> i} = D_{i+1} \cdots D_q.
\]

We show inductively on \( i \in \{0, \ldots, s\} \) that for every \( a = a_1 \cdots a_i \in A_{> i} \) (by convention \( a = e \) if \( i = 0 \)) and \( g \in G_{> i} \), we have

\[
\int_{Y_{H_{\leq i}}} f(y a^{-1} g) \, d\mu_{H_{\leq i}}(y) = (\mathcal{P}_{G_{\leq i}}, f)(\Gamma g) + \sum_{j=1}^i O \left( E_j(a_j)^{\kappa} \| f \|_q \right).
\]  

\[\tag{17}\]
with \( \kappa = \kappa_2 \) and \( q \) as in Lemma 11. Since \( H_{\leq 0} = G_{\leq 0} = Z(G) \), this is obvious for \( i = 0 \). To get this estimate for \( i = 1 \), we apply Lemma 11 to the function \( f_g(y) = (\mathcal{P}_{G_{\leq 0}} f)(yg) \) with \( g \in G_{i=1} \). Since \( G_1 \) commutes with \( G_{\leq 0} \) and \( G_{i=1} \), we have

\[
\|f_g|_{Y_G}\|_q \leq \|f\|_q \quad \text{and} \quad (\mathcal{P}_{G_i} \mathcal{P}_{G_{\leq 0}} f)(Y G) = (\mathcal{P}_{G_{\leq i}} f)(Y G).
\]

This proves Equation (17) with \( i = 1 \).

Now suppose that Equation (17) is proved at rank \( i \). As in Equation (11), for \( f \in \mathcal{C}_c(Y_G) \),

\[
\int_{Y_{H_{\leq i+1}}} f(y) d\overline{\mu}_{H_{\leq i+1}}(y) = \int_{(\Gamma \cap H_i) \setminus H_i} \int_{Y_{H_{\leq i}}} f(yh) d\overline{\mu}_{H_{\leq i}}(y) d\nu_{H_i}(h).
\]

Hence, for every \( a' = a_1 \ldots a_i \in A_{\geq 1}^+ \), \( a_{i+1} \in A_{\geq 1}^+ \) and \( g \in G_{i=1} \), with \( a = a'a_{i+1} \), by the right invariance of \( \overline{\nu}_{H_{i+1}} \) under \( H_{i+1} \) and by Equation (17), we have

\[
\int_{Y_{H_{\leq i+1}}} f(ya^{-1}g) d\overline{\mu}_{H_{\leq i+1}}(y)
= \int_{(\Gamma \cap H_{i+1}) \setminus H_{i+1}} \int_{Y_{H_{\leq i}}} f(y(a')^{-1}ha_{i+1}^{-1}g) d\overline{\mu}_{H_{\leq i}}(y) d\nu_{H_{i+1}}(h)
= \int_{(\Gamma \cap H_{i+1}) \setminus H_{i+1}} (\mathcal{P}_{G_{\leq i}} f)(\Gamma ha_{i+1}^{-1}g) d\nu_{H_{i+1}}(h) + \sum_{j=1}^i O \left( E_j(a_j)^\kappa \|f\|_q \right).
\]

Applying Lemma 11 to the functions \( \overline{f}_g : y \mapsto (\mathcal{P}_{G_{\leq i}} f)(yg) \) on \( Y_G \), we obtain

\[
\int_{(\Gamma \cap H_{i+1}) \setminus H_{i+1}} (\mathcal{P}_{G_{\leq i}} f)(\Gamma ha_{i+1}^{-1}g) d\nu_{H_{i+1}}(h)
= (\mathcal{P}_{G_{i+1}} \overline{f}_g)(\Gamma e) + O \left( E_{i+1}(a_{i+1})^{\kappa} \|\overline{f}_g\|_{Y_{G_{i+1}}} \|f\|_q \right)
= (\mathcal{P}_{G_{\leq i+1}} f)(\Gamma g) + O \left( E_{i+1}(a_{i+1})^{\kappa} \|f\|_q \right).
\]

This completes the proof of Equation (17). Since

\[
(\mathcal{P}_{G_{\leq i}} f)(\Gamma e) = \int_{Y_G} f d\overline{\nu}_G,
\]

the proposition follows. \( \square \)

**Proof of Proposition 8.** Since

\[
\int_{Y_{\mathcal{P}_\tau}} f d\mu_P = \int_{\Delta_T} \left( \int_{Y_H} f(ya^{-1}) d\mu_H(y) \right) \left( \prod_{a \in \Delta-I} \alpha(a)^{m_a} \right) d\omega_A(a),
\]

it follows from Proposition 9 and from Equation (5) that

\[
\int_{Y_{\mathcal{P}_\tau}} f d\mu_P = \mu_P(Y_{\mathcal{P}_\tau}) \int_{Y_G} f d\overline{\nu}_G + O \left( \|f\|_q \int_{\Delta_T} E^\kappa(a) \left( \prod_{a \in \Delta-I} \alpha(a)^{m_a} \right) d\omega_A(a) \right).
\]

For every \( i \in \{1, \ldots, s\} \) such that \( \Delta_i - I \neq \emptyset \), let \( \beta \in \Delta_i - I \). For every \( b_i \in A_i \), we have

\[
E_i(b_i) \leq e^{-\log \beta(b_i)}.
\]
Hence, by Lemma 6, we have, assuming that \( \kappa < \min_{\alpha \in \Delta - I} m_{\alpha} \) (which is possible),

\[
\int_{A_T} E_i(a_i)^\kappa \left( \prod_{\alpha \in \Delta - I} \alpha(a)^{m_{\alpha}} \right) d\omega_A(a) \leq c_A \left( \prod_{\alpha \in \Delta - I \setminus \{\beta\}} \int_0^{t_\beta} e^{m_{\alpha}s} ds \right) \int_0^{t_\beta} e^{(m_{\beta} - \kappa)s} ds = O \left( \mu_P(Y_{P_T}) e^{-\kappa t_\beta} \right).
\]

Therefore, since \( E^\kappa(a) = \sum_{1 \leq i \leq s : \Delta_i - I \neq \emptyset} E_i(a_i)^\kappa \), we have

\[
\int \mu_P(Y_{P_T}) \int_{Y_{P_T}} f \, d\mu_P = \int_{Y_G} f \, d\pi_G + O(e^{-\kappa \min T \|f\|_q}),
\]

as required. \( \square \)

**Step 3.** In this last step of the proof of Theorem 5, we will diffuse the orbits of \( L \cap H \) we want to count using bump functions, and apply the equidistribution result given by Proposition 8 in Step 2 to infer our main theorem.

Before starting this program, we rewrite the sum whose asymptotic we want to study in a more concise way. Let \( T, T' \in [0, +\infty[^{\Delta - I} \). By transversality (see for instance [Hir, p. 22, Theo. 3.3]), the intersection

\[
Z_{[T, T']} = Y_L \cap Y_{P_{[T, T']}}
\]

is a compact Riemannian submanifold of \( Y_G \), invariant under the right action of \( L \cap H \), and for every \( x \in Z_{[T, T']} \), we have \( T_x Z_{[T, T']} = (T_x Y_L) \cap (T_x Y_{P_{[T, T']}}) \). Since \( l \cap p = l \cap h \) by Equation (3), the Lie group \( L \cap H \) has open orbits in \( Z_{[T, T']} \). Hence the compact subset \( Z_{[T, T']} \) is a finite union of orbits of \( L \cap H \) (see the picture below when \( A \) is 1-dimensional).

![Diagram](image)

We will denote by \( \mu_{Z_{[T, T']}} \) the Riemannian measure on \( Z_{[T, T']} \). Using Riemannian volumes, we hence have

\[
\mu_{Z_{[T, T']}}(Z_{[T, T']}) = \sum_{y \in (Y_L \cap Y_{P_{[T, T']}})/(L \cap H)} \text{vol} \left( y(L \cap H) \right)
\]

\[
= \sum_{a \in A_{[T, T']}} \sum_{y \in (Y_L \cap Y_{H a^{-1}})/(L \cap H)} \text{vol} \left( y(L \cap H) \right).
\]

By Lemma 7 in Step 1, the quantity \( \mu_{Z_{[0, T']}}(Z_{[0, T']}) \), when divided by \( \text{vol}(Y_L) \), is the sum whose asymptotic we want to study.
We first start by studying the supports of the bump functions we will define: they will be appropriate neighbourhoods of $Y_L$ and $Z_{[T,T']^c}$. Fix $\epsilon > 0$, which will be appropriately chosen small enough later on. Consider the open ball $B(0, \epsilon)$ of center 0 and radius $\epsilon$ in the orthogonal complement $\mathfrak{g} \oplus \mathfrak{a}$ of $I \cap \mathfrak{p}$ in $\mathfrak{p}$, and let $\mathcal{O}_\epsilon = \exp B(0, \epsilon)$, which is contained in $P$.

Since $L$ is compact, if $\epsilon$ is small enough, the right action of $G$ on $Y_G$ induces a map $Y_L \times \mathcal{O}_\epsilon \rightarrow Y_G$, with $(y, g) \mapsto yg$, which is a smooth diffeomorphism onto an open neighbourhood $Y_L \mathcal{O}_\epsilon$ of the submanifold $Y_L$ in $Y_G$. Similarly, if $\epsilon$ is small enough, then for every $T,T' \in [0, +\infty[^{\Delta^{-1}}$, the map $Z_{[T,T']^c} \times \mathcal{O}_\epsilon \rightarrow Y_P$ defined by $(y, g) \mapsto yg$ is a smooth diffeomorphism onto an open neighbourhood $Z_{[T,T']^c} \mathcal{O}_\epsilon$ of the submanifold $Z_{[T,T']^c}$ in $Y_P$. If $\eta \in \mathbb{R}$ and $T'' = (t''_\alpha)_{\alpha \in \Delta^{-1}} \in [0, +\infty[^{\Delta^{-1}}$, we denote $T'' + \eta = (t''_\alpha + \eta)_{\alpha \in \Delta^{-1}}$.

Lemma 12 There exists $c > 0$ such that if $\epsilon > 0$ is small enough, for every $T,T' \in [0, +\infty[^{\Delta^{-1}}$, then

$$Z_{[T+\epsilon,T'+\epsilon]} \mathcal{O}_\epsilon \subset Y_L \mathcal{O}_\epsilon \cap Y_P_{[T,T']} \subset Z_{[T-\epsilon,T'+\epsilon]} \mathcal{O}_\epsilon .$$

Proof. We first claim that there exists $c > 0$ such that

$$P_{[T+\epsilon,T'+\epsilon]} \subset P_{[T,T']} \mathcal{O}_\epsilon \subset P_{[T-\epsilon,T'+\epsilon]} .$$

Since the product map $(h, a) \mapsto ha$ is a diffeomorphism from $H \times A$ to $P$, since $\mathcal{O}_\epsilon$ is contained in $P$, and since the distances are Riemannian ones, there exists $c_1 > 0$ such that if $\epsilon > 0$ is small enough, then for every $g \in \mathcal{O}_\epsilon$, there exist $h \in H$ and $a \in A$ with $g = ha$ and $d(a, e) \leq c_1 \epsilon$. Since the Riemannian distance on $A$ is equivalent to the image by exp of the distance on $a$ defined by the norm $\|x\| = \max_{\alpha \in \Delta^{-1}} \|\log(\exp a x)\|$, there exists $c_2 > 0$ such that $|\log a(a)\| \leq c_2 d(a, e)$ for every $a \in A$.

Let $g \in \mathcal{O}_\epsilon$, $h \in H$ and $a \in A$ be such that $g = ha$ and $d(a, e) \leq c_1 \epsilon$. Since $A$ normalises $H$, we have $HA^{-1}_{[T,T']^c} g = HA^{-1}_{[T,T']^c} ha = HA^{-1}_{[T,T']^c} a$. Hence $HA^{-1}_{[T,T']^c} g$ is contained in $HA^{-1}_{[T-c_1 c_2 T', T+c_1 c_2 T]}$ and contains $HA^{-1}_{[T+c_1 c_2 T', T'-c_1 c_2 T]}$. This proves the first claim.

Now, let $y \in Y_L$, $g \in \mathcal{O}_\epsilon$ and $p \in P_{[T,T']^c}$ be such that $yg = \pi(p)$. Then $y = \pi(pg^{-1})$. Since $\mathcal{O}_\epsilon$ is invariant by taking inverses, $pg^{-1}$ belongs to $P_{[T,T']^c} \mathcal{O}_\epsilon$, hence by the first claim, $yg \in Z_{[T-\epsilon,T'+\epsilon]} \mathcal{O}_\epsilon$. The left inclusion is proven similarly.

We now study the properties of the Riemannian measures on the neighbourhoods $Y_L \mathcal{O}_\epsilon$ and $Z_{[T,T']^c} \mathcal{O}_\epsilon$.

Lemma 13 For every $\epsilon > 0$ small enough, there exist smooth measures $\nu$ and $\tilde{\nu}$ on $\mathcal{O}_\epsilon$ such that the product maps $Y_L \times \mathcal{O}_\epsilon \rightarrow Y_G$ and $Z_{[T,T']^c} \times \mathcal{O}_\epsilon \rightarrow Y_P$ send the product measures $\mu_L \otimes \nu$ and $\mu_{Z_{[T,T']^c}} \otimes \tilde{\nu}$ to the restricted measures $\mu_{Y_L} \mathcal{O}_\epsilon$ and $\mu_{Z_{[T,T']^c}} \mathcal{O}_\epsilon$, respectively. Furthermore, $\frac{\partial \tilde{\nu}}{\partial \nu}(e) = 1$.

Proof. Since the measure $\mu_{Y_L} \mathcal{O}_\epsilon$ (respectively $\mu_{Z_{[T,T']^c}} \mathcal{O}_\epsilon$) is Riemannian, it disintegrates with respect to the trivialisable fibration $Y_L \mathcal{O}_\epsilon \rightarrow Y_L$ (respectively $Z_{[T,T']^c} \mathcal{O}_\epsilon \rightarrow Z_{[T,T']^c}$) with measure on the basis $\mu_L$ (respectively $\mu_{Z_{[T,T']^c}}$), and conditional measures $\nu_y$ (respectively $\tilde{\nu}_y$) on the fibers $y \mathcal{O}_\epsilon$ for all $y \in Y_L$ (respectively $y \in Z_{[T,T']^c}$). By left invariance of the measures $\omega_L$ and $\omega_{L \cap H}$, there exist smooth measures $\nu$ (respectively $\tilde{\nu}$) on $\mathcal{O}_\epsilon$ such that
Similarly, since $q + a$ is orthogonal to $I$ (respectively $I \cap b$) by Equation (4), the manifold $yC_\epsilon$ is orthogonal to $Y_L$ (respectively $Z_{[T,T']}^q$) at every $y \in Y_L$ (respectively $y \in Z_{[T,T']}^q$). Hence any orthonormal frame $F$ of $T_y(yC_\epsilon)$ at a given $y \in Z_{[T,T']}$ may be completed to an orthonormal frame whose last vectors form a basis of $T_yY_L$, whose first vectors form a basis of $T_yZ_{[T,T']}$. By desintegration, the orthogonal frame $F$ has the same infinitesimal volume for $\nu$ and $\bar{\nu}$. The last assertion follows.

Let us now define our bump functions. By the standard construction of bump functions on manifolds, for every $q \in \mathbb{N}$, there exists $\kappa' > 0$ such that for every $\epsilon > 0$ small enough, there exists a $C^q$ map $\psi_\epsilon$ from $\Omega_\epsilon$ to $[0, +\infty[$, with compact support, such that $\int \psi_\epsilon \ d\nu = 1$ and $\|\psi_\epsilon\|_q = O(\epsilon^{-\kappa'})$. Since $\frac{d\nu}{d\bar{\nu}} = 1 + O(\epsilon)$ on $\Omega_\epsilon$ by Lemma 13, we have

$$\int_{\Omega_\epsilon} \psi_\epsilon \ d\bar{\nu} = 1 + O(\epsilon) \ .$$

For every $\epsilon > 0$ small enough, define $f_\epsilon : Y_G \to [0, +\infty]$ by $f_\epsilon(y) = 0$ if $y \notin Y_L \Omega_\epsilon$ and $f_\epsilon(yg) = \psi_\epsilon(g)$ for every $y \in Y_L$ and $g \in \Omega_\epsilon$. Note that $f_\epsilon$ is $C^q$ with compact support, since $Y_L$ is compact. We have

$$\int_{Y_G} f_\epsilon \ d\bar{\mu} = \int_{Y_G} f_\epsilon \ d\mu_G \frac{\text{vol}(Y_G)}{\text{vol}(Y_L)} = \int_{Y_G} \int_{\Omega_\epsilon} \psi_\epsilon(g) \ d\mu_L(y) d\nu(g) = \text{vol}(Y_L) \frac{\text{vol}(Y_L)}{\text{vol}(Y_G)} ,$$

and $\|f_\epsilon\|_q = O(\epsilon^{-\kappa'})$.

Since the support of $f_\epsilon$ is contained in $Y_L \Omega_\epsilon$, by Lemma 13, and by the right inclusion in Lemma 12, we have, for every $T \in [0, +\infty[\widehat{T}^{-1}$,

$$\int_{Y_T} f_\epsilon \ d\mu_P \leq \int_{Z_{[-\epsilon,T+\epsilon]} \Omega_\epsilon} f_\epsilon \ d\mu_P \leq \int_{y \in \Omega_\epsilon} \int_{y \in Z_{[-\epsilon,T+\epsilon]}} Y_L \psi_\epsilon(g) \ d\mu_L(y) d\nu(g) = \text{vol}(Z_{[-\epsilon,T+\epsilon]}) (1 + O(\epsilon)) \ .$$

Similarly, since $f_\epsilon \geq 0$ and by the left inclusion in Lemma 12, we have, for every $T \in [0, +\infty[\widehat{T}^{-1}$,

$$\int_{Y_T} f_\epsilon \ d\mu_P \geq \int_{Z_{[-\epsilon,T+\epsilon]} \Omega_\epsilon} f_\epsilon \ d\mu_P = \text{vol}(Z_{[\epsilon,T-\epsilon]}) (1 + O(\epsilon)) \ .$$

Finally, we apply Step 2 to our bump functions. By Proposition 8, we have the equality

$$\frac{1}{\mu_P(Y_{T^2})} \int_{Y_T} f_\epsilon \ d\mu_P = \int_{Y_G} f_\epsilon \ d\mu_G + O (e^{-\kappa \min T} \|f_\epsilon\|_q) .$$

Hence, by the properties of $f_\epsilon$,

$$\int_{Y_T} f_\epsilon \ d\mu_P = \frac{\text{vol}(Y_L) \mu_P(Y_{P^2})}{\text{vol}(Y_G)} (1 + O(\epsilon^{-\kappa'} e^{-\kappa \min T})) .$$

Let $\delta = \frac{\kappa}{\kappa + 1} > 0$ and $\epsilon = e^{-\delta \min T}$ (which tends to 0 as $\min T$ tends to $+\infty$). Then $e^{-\kappa} e^{-\kappa \min T} = e^{(\kappa' \delta - \kappa) \min T} = e^{-\delta \min T}$. By the equations (19) and (20), and by Lemma 19.
6, we have, as $\min T$ tends to $+\infty$,

$$\text{vol}(Z_{[c,T,cT]}) \leq \left( \int_{Y_{\mathcal{T}}} f_x \, d\mu_T \right) (1 + O(e^{-\delta \min T}))$$

$$= \frac{\text{vol}(Y_L) \mu_P(Y_{\mathcal{T}})}{\text{vol}(Y_G)} (1 + O(e^{-\delta \min T}))$$

$$= \frac{\text{Vol}(\Lambda^{\vee} \setminus A) \text{vol}(Y_L) \text{vol}(Y_H)}{\text{vol}(Y_G)} \left( \prod_{\alpha \in \Delta - I} \frac{e^{m_{\alpha} t_\alpha}}{m_{\alpha}} \right) (1 + O(e^{-\delta \min T})) .$$

Since $e^x = 1 + O(x)$ as $x$ tends to 0, we have $e^{e^{-\delta \min T} \sum_{\alpha \in \Delta - I} m_{\alpha}} = 1 + O(e^{-\delta \min T})$ as $\min T$ tends to $+\infty$. Since $Z_{[0,cT]}$ is bounded, we hence have, as $\min T$ tends to $+\infty$,

$$\text{vol}(Z_{[0,T]}) \leq \frac{\text{Vol}(\Lambda^{\vee} \setminus A) \text{vol}(Y_L) \text{vol}(Y_H)}{\text{vol}(Y_G)} \left( \prod_{\alpha \in \Delta - I} \frac{e^{m_{\alpha} t_\alpha}}{m_{\alpha}} \right) (1 + O(e^{-\delta \min T})) .$$

The converse inequality is proven similarly, using Equation (18) instead of Equation (19).

Since $\sum_{\alpha \in AT} \sum_{x \in \mathcal{L} \cap \Gamma \setminus \{(\nu, \rho(\mathcal{L}(R) \alpha) \cap \nu(\Gamma) \nu_0)\}} w_{L,\rho|L}(x) = \frac{\text{vol}(Z_{[0,T]})}{\text{vol}(Y_G)}$ as said in the beginning of Step 3, this ends the proof of Theorem 5.

\[\square\]

**Remark 14** Let $G, P, \mathbf{A}, \mathbf{M}, U, L, V, \rho, v_0$ be as in the statement of Theorem 5, and assume furthermore that $G$ is simply connected. Then we have the following counting results using the standard Siegel weights.

There exists $\delta > 0$ such that, as $T = (t_\alpha)_{\alpha \in \Delta - I} \in [0, +\infty[ \cup \Delta - I$ and $\min_{\alpha \in \Delta - I} t_\alpha$ tends to $+\infty$,

$$\sum_{\alpha \in AT} \sum_{x \in \mathcal{L} \setminus \{(\nu, \rho(L(R) \alpha) \cap \nu(\Gamma) \nu_0)\}} w_{L,\rho|L}(x) = \frac{\text{vol}(\mathbf{M}(\mathcal{L}(R)) \setminus \mathbf{M}(\mathcal{L}(R))) \text{vol}(\Lambda^{\vee} \setminus \mathbf{A}(\mathcal{L}(R)))}{\text{vol}(\mathbf{G}(\mathcal{L}(R)) \setminus \mathbf{G}(\mathcal{L}))} \left( \prod_{\alpha \in \Delta - I} \frac{e^{m_{\alpha} t_\alpha}}{m_{\alpha}} \right) (1 + O(e^{-\delta \min_{\alpha \in \Delta - I} t_\alpha}) .$$

The proof is the same as the one of Theorem 5, with the following modifications. Since $G$ is simply connected, $G(R)$ is connected (see for instance [PR, §7.2]). Hence with the previous notation, we have $G = G(R) \setminus \Gamma \setminus \{(\nu, \rho(\mathcal{L}(R)) \cap \nu(\Gamma) \nu_0)\}$ and $G$ was useful. Now take $L = L(R)$ instead of $L = L(R) \setminus \mathcal{L}(R)$ (which is still contained in $G$, but would not have been if $G$ was taken to be $G(R) \setminus \mathcal{L}(R)$ while $G(R)$ is not connected). Though $L$ and $Y_L$ may be no longer connected, the proof stays valid.

To end this section, we give two slightly different versions of Theorem 5 when $P$ is maximal.

**Theorem 15** Let $G$ be a connected reductive linear algebraic group defined over $\mathbb{Q}$, without nontrivial $\mathbb{Q}$-characters. Let $P$ be a maximal (proper) parabolic subgroup of $G$ defined over $\mathbb{Q}$, and let $P = AMU$ be a relative Langlands decomposition of $P$, such that $A(R) \setminus \mathcal{L}$ is a one-parameter subgroup $(\alpha_{\lambda})_{\lambda \in \mathcal{L}}$, with $\lambda = \log \det (\text{Ad} \alpha_1)|_{\mathcal{L}} > 0$, where $\mathcal{L}$ is the Lie algebra of $U(R)$. Let $\rho : G \to GL(V)$ be a rational representation of $G$ defined over $\mathbb{Q}$ such that there exists $v_0 \in V(\mathbb{Q})$ whose stabiliser in $G$ is $MU$. Let $L$ be a reductive algebraic
subgroup of $G$ defined and anisotropic over $\mathbb{Q}$. Assume that $LP$ is Zariski-open in $G$ and that for every $s \in \mathbb{R}$, the orbit $X_s = \rho(La_s)v_0$ is Zariski-closed in $V$.

(1) Endow $G(\mathbb{R})$ with a left-invariant Riemannian metric, for which the Lie algebras of $MU(\mathbb{R})$ and $A(\mathbb{R})$ are orthogonal, and the orthogonal of the Lie algebra of $P(\mathbb{R})$ is contained in the Lie algebra of $L(\mathbb{R})$. Let $G = G(\mathbb{R})_0$ and $\Gamma = G(\mathbb{Z}) \cap G$. There exists $\delta > 0$ such that, as $t \geq 0$ tends to $+\infty$,

$$
\sum_{0 \leq s \leq t} \sum_{[x] \in (L(\mathbb{R})_0 \cap \Gamma) \setminus (\rho(L(\mathbb{R})_0 a_s) v_0 \cap \rho(\Gamma) v_0)} w'_{L(\rho) L}(x) = \frac{\operatorname{vol}((MU \cap \Gamma) \setminus (MU \cap G))}{\lambda \operatorname{vol}(\Gamma \setminus G)} \frac{\operatorname{vol}(a_T^2 \setminus A(\mathbb{R})_0)}{e^\lambda + O(e^{(\lambda - \delta)t})}.
$$

(2) Let $\Lambda$ be a $\mathbb{Z}$-lattice in $V(\mathbb{Q})$ invariant under $G(\mathbb{Z})$, and let $A^{\text{prim}}$ be the subset of indivisible elements of $\Lambda$. Assume that $\rho$ is irreducible over $\mathbb{C}$. Then there exist $c, \delta > 0$ such that, as $t \geq 0$ tends to $+\infty$,

$$
\sum_{0 \leq s \leq t} \sum_{[x] \in (L(\mathbb{Z}) \cap L(\mathbb{R})_0) \setminus (X_s \cap A^{\text{prim}})} w'_{L(\rho) L}(x) = c e^\lambda + O(e^{(\lambda - \delta)t}).
$$

Proof. (1) In this case, $\Delta - I$ consists of one simple root $\alpha_0$. Changing the parametrisation of the one-parameter subgroup $(a_s)_{s \in \mathbb{R}}$ appearing in Theorem 15 by multiplying $s$ by a positive constant does not change the asymptotic formula in the statement of Theorem 15 (1). Hence we may assume that $a_1 = (\alpha_0)^\gamma$, hence that the group $a_T^2$ generated by $a_1$ is equal to the lattice $\Lambda^\gamma$. The constant $\lambda$ defined in Theorem 15 is then equal to $m_{\alpha_0}$. The first part of Theorem 15 hence follows from Theorem 5.

(2) We start by proving two lemmas.

Lemma 16 If $\rho$ is irreducible, then the stabiliser of $Cv_0$ in $G$ is $P$ and there exists $\chi \in \mathbb{R}$ such that $a_s v_0 = e^{\chi s} v_0$ for every $s \in \mathbb{R}$.

Proof. Let $T$ be a maximal torus of $G$ containing $S$, and let $\Delta_T$ be a set of primitive roots of $G$ relative to $T$, whose set of nonzero restrictions to $S$ is $\Delta$ (see for instance [Bor3, §21.8]). Then the unipotent subgroup $U^+_T$, whose Lie algebra is the sum of the positive root spaces of $G$ relative to $T$, is contained in $MU$. By the properties of the highest weights, if $\rho$ is irreducible, the space $\{v \in V : U^+_T v = v\}$ is one-dimensional, hence equal to $\mathbb{C}v_0$. Since $A$ normalises $MU$, hence $U^+_T$, it preserves $\mathbb{C}v_0$, and the result follows, by the connectedness of $A$.

Lemma 17 There exist $v_1, \ldots, v_k$ in $A^{\text{prim}}$ such that $A^{\text{prim}} \cap Gv_0 = \bigsqcup_{i=1}^k \Gamma v_i$.

Proof. By [Bor3, Prop. 20.5], the natural map $G(\mathbb{Q}) \to (G/P)(\mathbb{Q})$ is onto. Since $Gv_0 \simeq G/MU$, this implies that every $x \in (Gv_0)(\mathbb{Q})$ may be written as $x = gpv_0$ for some $g \in G(\mathbb{Q})$ and $p \in P$. Hence by Lemma 16,

$$(Gv_0)(\mathbb{Q}) \subset \mathbb{C}^\times G(\mathbb{Q})v_0.$$

By [Bor2, Prop. 15.6], there exists a finite subset $F$ of $G(\mathbb{Q})$ such that $G(\mathbb{Q}) = \Gamma FP(\mathbb{Q})$. Hence,

$$(Gv_0)(\mathbb{Q}) \subset \mathbb{C}^\times \Gamma Fv_0,$$

21
In particular, we conclude that there exist \( v_1, \ldots, v_k \) in \( \Lambda^{prim} \) such that
\[
\Lambda^{prim} \cap Gv_0 \subset \bigsqcup_{i=1}^k \mathbb{C}^x_{v_i}.
\]
Since for every \( v \in \Lambda^{prim} \),
\[
\mathbb{C}^x v \cap \Lambda^{prim} = \{ \pm v \},
\]
this implies the lemma. \( \square \)

Now, since the identity component \( L \) of \( L(\mathbb{R}) \) has finite index in \( L(\mathbb{R}) \), there exist \( 0 \leq \ell \leq k \) in \( L(\mathbb{R}) \) such that \( L(\mathbb{R}) = \bigsqcup_{j=1}^{k'} L_{\ell_j}. \) Hence, since \( v_0 \) belongs to \( V(\mathbb{R}) \) and \( X_s \subset Gv_0 \), by Lemma 16 and Lemma 17, we have
\[
X_s \cap \Lambda^{prim} = (L(\mathbb{R}) e^{x_s v_0}) \cap (\Lambda^{prim} \cap Gv_0) = \bigsqcup_{1 \leq i \leq k, 1 \leq j \leq k'} e^{x_s} L_{\ell_j} v_0 \cap \Gamma v_i.
\]
(21)
If \( L_{\ell_j} v_0 \cap \Gamma v_i \) is nonempty, fix \( v_{i,j} \in L_{\ell_j} v_0 \cap \Gamma v_i \). In particular, there exist \( \gamma \in \Gamma \) and \( \ell \in L \) such that \( v_{i,j} = \ell_{\ell_j} v_0 = \gamma v_i \). Since \( v_{i,j} \in V(\mathbb{Q}) \), we have \( v_{i,j} \in V(\mathbb{Q}) \). Hence the stabiliser \( P_{i,j} \) of \( v_{i,j} \) in \( G \) is an algebraic subgroup defined over \( \mathbb{Q} \). Since \( v_{i,j} \) is in the \( G \)-orbit of \( v_0 \), the stabilisers of \( v_0 \) and of \( v_{i,j} \) are conjugate, hence \( P_{i,j} \) is a parabolic subgroup of \( G \). Since two parabolic subgroups of \( G \), which are defined over \( \mathbb{Q} \) and conjugate in \( G \), are conjugated by an element of \( G(\mathbb{Q}) \) (see for instance \([\text{Bor4}, \text{Theo. 20.9 (iii)}]\)), there exists \( \alpha_{i,j} \in G(\mathbb{Q}) \) such that \( P_{i,j} = \alpha_{i,j} P_{\alpha_{i,j}^{-1}} \). Furthermore, using Lemma 16, we have \( C_{v_{i,j}} = C_{\alpha_{i,j} v_0} \). A relative Langlands decomposition of \( P_{i,j} \) is \( A_{i,j} M_{i,j} U_{i,j} \) where
\[
A_{i,j} = \alpha_{i,j} P_{\alpha_{i,j}^{-1}} \quad M_{i,j} = \alpha_{i,j} M_{\alpha_{i,j}^{-1}} \quad U_{i,j} = \alpha_{i,j} U_{\alpha_{i,j}^{-1}}.
\]
We have \( A_{i,j}(\mathbb{R})_0 = (a_{i,j} = \alpha_{i,j} a_{s} \alpha_{i,j}^{-1})_{s \in \mathbb{R}} \) and the Lie algebra of \( U_{i,j}(\mathbb{R}) \) is \( U_{i,j} = \text{Ad} \alpha_{i,j}(\mathbb{R}) \). Hence \( a_{i,j} = e^{x_s v_{i,j}} \) for every \( s \in \mathbb{R} \) and
\[
\log \text{det}(\text{Ad} a_{i,j})|_{U_{i,j}} = \lambda ,
\]
for every \( i, j \) with \( L_{\ell_j} v_0 \cap \Gamma v_i \neq \emptyset \).

By Assertion (1) of Theorem 15 applied to the (maximal) parabolic subgroup \( P_{i,j} \) defined over \( \mathbb{Q} \), there exist \( c_{i,j}, \delta_{i,j} > 0 \) (with \( c_{i,j} \) explicit) such that, as \( t \geq 0 \) tends to \( +\infty \),
\[
\sum_{0 \leq s \leq t} |x|^{(L \cap \Gamma)}(La_{i,j}^s v_{i,j} \cap \Gamma v_{i,j}) w'_{L,\rho|L}(x) = c_{i,j} e^{\delta t} + O(e^{(\lambda - \delta) t}) .
\]
Hence, using the equations (7) and (21), with \( \delta = \min_{i,j} \delta_{i,j} \) and \( c = \sum_{i,j} c_{i,j} \), we have, as \( t \geq 0 \) tends to \( +\infty \),
\[
\sum_{0 \leq s \leq t} |x|^{(L \cap \Gamma)}(X_s \cap \Lambda^{prim}) w'_{L,\rho|L}(x) = \sum_{1 \leq i \leq k} \sum_{1 \leq j \leq k'} \sum_{0 \leq s \leq t} |x|^{(L \cap \Gamma)}(La_{i,j}^s v_{i,j} \cap \Gamma v_{i,j}) w'_{L,\rho|L}(x) = c e^{\delta t} + O(e^{(\lambda - \delta) t}) .
\]
This ends the proof of Assertion (2) of Theorem 15. \( \square \)

**Remark.** Using Remark 14 instead of Theorem 5 in the above proof gives Theorem 2 and Theorem 1 in the introduction.

22
3 Examples

In this section, we give several examples to illustrate our main results.

3.1 Counting inequivalent representations of integers by norm forms

Let \( n \geq 2 \). A decomposable form \( F(x_1, \ldots, x_n) \) is a polynomial in \( n \) variables with coefficients in \( \mathbb{Q} \), which is the product of \( d \) linear forms with coefficients in \( \overline{\mathbb{Q}} \). In particular, a norm form is a decomposable form \( N_{K/\mathbb{Q}}(\alpha_1 x_1 + \cdots + \alpha_n x_n) \) where \( \alpha_1, \ldots, \alpha_n \) are fixed elements in a number field \( K \) of degree \( d \) and \( x_1, \ldots, x_n \) are rational variables. Existence of integral solutions to the equation \( F(x) = m \) is a difficult problem (see, for instance, [CTX]). Here we demonstrate how our main result applies to integral solutions of the inequality \( |F(x)| \leq m \), which can be also studied using elementary methods as in [Lan, Ch. VI]. See also, following an approach of Linnik and Sarnak, the papers [EO, GO, Oh1], using dilations of relatively compact subsets.

**Corollary 18** Let \( n \geq 2 \), let \( F \in \mathbb{Q}[x_1, \ldots, x_n] \) be a rational polynomial in \( n \) variables, which is irreducible over \( \mathbb{Q} \), splits as a product of \( n \) linearly independent over \( \mathbb{C} \) linear forms with coefficients in \( \overline{\mathbb{Q}} \), and satisfies \( F^{-1}(\{0, +\infty\}) \neq \emptyset \). Let \( \Gamma_F = \{ g \in \text{SL}_n(\mathbb{Z}) : F \circ g = F \}, \) and for every \( k \in \mathbb{Q} \), let \( \Sigma_k \) be the set of \( x \in \mathbb{Z}^n \) such that \( F(x) = k \). Then there exist \( c = c(F) > 0 \) and \( \delta = \delta(n) \in ]0, 1[ \) such that, as \( r \to +\infty \),

\[
\sum_{k \in [1, r]} \text{Card}(\Gamma_F \setminus \Sigma_k) = c \cdot r + O(r^\delta).
\]

It is easy to see that the above sum is indeed finite, and that the irreducibility assumption is necessary. With \( \mathbf{L} \) the stabiliser of \( F \) in \( \text{SL}_n(\mathbb{C}) \), \( \mathbf{V} = \mathbb{C}^n \), \( \Lambda = \mathbb{Z}^n \) and \( \pi \) the inclusion of \( \mathbf{L} \) in \( \text{GL}(\mathbf{V}) \), this result fits into the program described in the beginning of the introduction, since \( \Gamma_F = \mathbf{L}(\mathbb{Z}) \), the algebraic torus \( \mathbf{L} \) is anisotropic over \( \mathbb{Q} \) (see Lemma 19) and acts simply transitively on the affine subvariety of \( \mathbf{V} \) with equation \( F(x) = k \) if \( k \neq 0 \), noting that the Siegel weights \( w_{\mathbf{L}, \pi}(u) = 1/\text{vol}(\mathbf{L}(\mathbb{Z}) \setminus \mathbf{L}(\mathbb{R})) \) are then constant.

When \( K \) is a number field of degree \( n \) with ring of integers \( \mathcal{O}_K \), taking an integral basis \( (\alpha_1, \ldots, \alpha_n) \) of \( K \), and \( F(x_1, \ldots, x_n) \) the particular norm form \( N_{K/\mathbb{Q}}(\alpha_1 x_1 + \cdots + \alpha_n x_n) \), we recover the well-known counting result of the number of nonzero integral ideals of \( \mathcal{O}_K \) with trivial ideal class and norm at most \( s \) (see for instance [Lan, Theorem 3, page 132]), giving

\[
\{ \text{an ideal in } \mathcal{O}_K : N_{K/\mathbb{Q}}(a) \leq s \} = \frac{2^{r_1}(2\pi)^{r_2}R_Kh_K}{\omega_K \sqrt{|D_K|}} s + O(s^{1-\epsilon}),
\]

where \( r_1 \) and \( r_2 \) are the numbers of real and complex conjugate embeddings of \( K \), \( R_K \) is the regulator of \( K \), \( h_K \) is the ideal class number of \( K \), \( \omega_K \) is the number of roots of unity of \( \mathcal{O}_K \), \( D_K \) is the discriminant of \( K \) and \( \epsilon = 1/n \).

**Proof of Corollary 18.** In order to apply Theorem 1, let us first define the objects appearing in its statement.

Let \( \mathbf{G} = \text{SL}_n(\mathbb{C}) \) which is a \( (\mathbb{Q} \text{-split}) \) quasi-simple simply connected linear algebraic group without nontrivial \( \mathbb{Q} \)-characters. Let \( \mathbf{V} = \mathbb{C}^n \), \( \Lambda = \mathbb{Z}^n \) which is a \( \mathbb{Z} \)-lattice in \( \mathbf{V}(\mathbb{Q}) \) invariant under \( \mathbf{G}(\mathbb{Z}) \), \( (e_1, \ldots, e_n) \) the canonical basis of \( \mathbf{V} \) and \( \rho : \mathbf{G} \to \text{GL}(\mathbf{V}) \) the monomorphism mapping a matrix \( x \) to the linear automorphism of \( \mathbf{V} \) whose matrix in the
canonical basis is $x$, which is an irreducible rational representation over $\mathbb{C}$. To simplify
the notation, we denote $\rho(g)v = gv$ for every $g \in G$ and $v \in V$. Let $P$ be the stabiliser
in $G$ of the line generated by $e_1$, which is a maximal (proper) parabolic subgroup of $G$
deﬁned over $\mathbb{Q}$. With $I_k$ the identity $k \times k$ matrix and $s \in \mathbb{R}$, let $U = \{ \begin{pmatrix} 1 & u \\ 0 & I_{n-1} \end{pmatrix} : u \in \\
M_{1,n-1}(\mathbb{C}) \}, a_s = \left( e^{\frac{s}{\pi}} 0 \\ 0 e^{-\frac{s}{\pi(n-\ell)}} I_{n-1} \right)$, and $M = \{ \begin{pmatrix} 1 & 0 \\ 0 & m \end{pmatrix} : m \in SL_{n-1}(\mathbb{C}) \}$. With $A$
the centraliser of $M$ in $G$, we have that $P = AMU$ is a relative Langlands decomposition
of $P$ over $\mathbb{Q}$, and the identity component of $A(\mathbb{R})$ is the one-parameter subgroup $(a_s)_{s \in \mathbb{R}}$.
With $\mathfrak{u}$ the Lie algebra of $U(\mathbb{R})$, an immediate computation gives
\[ \lambda = \log \det(Ad a_1)|_{\mathfrak{u}} = 1 > 0. \] (23)

Since $F$ is homogeneous, as $F$ takes a positive value (and equivalently), there exists
$v_0 \in \mathbb{Z}^n$ such that $F(v_0) > 0$. We may assume that $v_0$ is primitive up to rescaling it,
and after an integral change of variable (which does not change the set of integral
representations of a real number by $F$), we may assume that $v_0 = e_1$. Note that the
stabiliser of $v_0$ in $G$ is then precisely $MU$.

We denote by $L$ the stabiliser of $F$ in $G$ and by $\pi : L \to GL(V)$ the restriction of $\rho$ to
$L$. By the linear independence over $\mathbb{C}$ assumption, $L$ is a maximal algebraic torus defined
over $\mathbb{Q}$ in $G$ (hence $L$ is reductive, but not semisimple). For every $z \in \mathbb{C} - \{0\}$, the group $L$
acts simply transitively on the affine hypersurface $F^{-1}(z)$. Hence, with $v_s = a_s v_0 = e^{s} v_0$,
the orbit
\[ X_s = L v_s = F^{-1}(F(v_s)) = F^{-1}(e^{s} F(v_0)) \] (24)
(since $F$ is homogeneous of degree $n$) is Zariski-closed in $V$.

Let us now check in two lemmas that the hypotheses of Theorem 1 are satisﬁed by
these objects.

**Lemma 19** *The algebraic torus $L$ is anisotropic over $\mathbb{Q}$.*

**Proof.** By [Koc, Theo. 2.3.3, page 38], there exist $a \in \mathbb{Q} - \{0\}$ and linearly independant
linear forms $\ell_1, \ldots, \ell_n$ on $\mathbb{C}^n$ with coefficients in $\overline{\mathbb{Q}}$ such that $F = a \prod_{i=1}^{n} \ell_i$ and the absolute
Galois group $Gal(\overline{\mathbb{Q}}/\mathbb{Q})$ acts transitively on the set $\{ \ell_1, \ldots, \ell_n \}$. Let $B$ be the basis of $\mathbb{C}^n$
whose dual basis is $(\ell_1, \ldots, \ell_n)$. The algebraic torus $L$ is the subgroup of the elements of
$G$ whose matrix in the basis $B$ is diagonal. For $1 \leq i \leq n$, let $\chi_i$ be the character (deﬁned
over $\overline{\mathbb{Q}}$) of $L$ which associates to an element of $L$ the $i$-th diagonal element of its matrix in $B$.
Note that $Gal(\overline{\mathbb{Q}}/\mathbb{Q})$ acts transitively on the set $\{ \chi_1, \ldots, \chi_n \}$. Any character of $L$
may be uniquely written $\prod_{i=1}^{n} \chi_{k_i}$ with $k_1, \ldots, k_n \in \mathbb{Z}$. Any $\mathbb{Q}$-character $\prod_{i=1}^{n} \chi_{k_i}$ of $L$, being
invariant under $Gal(\overline{\mathbb{Q}}/\mathbb{Q})$, should have $k_1 = \cdots = k_n$ by transitivity, hence is trivial. The
result follows, since an algebraic torus deﬁned over $\mathbb{Q}$ without nontrivial $\mathbb{Q}$-characters is
anisotropic over $\mathbb{Q}$, that is, it contains no nontrivial $\mathbb{Q}$-split torus (see for instance [Bor3,
page 121], though this reference uses a different meaning of anisotropic). \hfill \Box

**Lemma 20** *The intersection $L \cap P$ is ﬁnite and $LP$ is Zariski-open in $G$.*

**Proof.** Let us prove that the algebraic group $L \cap P$ is ﬁnite. Since an algebraic group
has only ﬁnitely many components, we only have to prove that its identity component
...

24
the Galois group $V$ basis of $Q$ by the map $Q \to \mathbb{C}ge_1$. We write $e_1 = \sum_{i=1}^n c_i w_i$ where $\mathcal{B} = (w_i)_{1 \leq i \leq n}$ is a diagonalisation basis of $V$ for the action of the algebraic torus $L$, as in the proof of Lemma 19. Since $L$ is anisotropic over $Q$ by Lemma 19, this implies that $S$ is trivial, and proves the first claim.

Now, the homogeneous space $G/P$ is identified with the complex projective space $\mathbb{P}(\mathbb{C}^n)$ by the map $g \mapsto \mathbb{C}ge_1$. We write $e_1 = \sum_{i=1}^n c_i w_i$ where $\mathcal{B} = (w_i)_{1 \leq i \leq n}$ is a diagonalisation basis of $V$ for the action of the algebraic torus $L$, as in the proof of Lemma 19. Since $L$ is anisotropic over $Q$ by Lemma 19, this implies that $S$ is trivial, and proves the first claim.

To conclude the proof of Corollary 18, we relate the two counting functions in the statements of Corollary 18 and Theorem 1.

For every $s > 0$ and $p \in \mathbb{N} - \{0\}$, let $A_s^{(p)}$ be the set of integral points of $X_s$ whose coefficients have their greatest common divisor equal to $p$. Note that $A_s^{(1)} = X_s \cap \Lambda_{\text{prim}}$ is the set of primitive integral points of $X_s$. With $N_s^{(p)} = \text{Card}(L(Z) \setminus A_s^{(p)})$, we have $\text{Card}(L(Z) \setminus X_s(Z)) = \sum_{p=1}^{+\infty} N_s^{(p)}$, and $N_s^{(p)} = N_s^{(1)} s^{-\ln(p^n)}$, since $X_s = \log$ by the homogeneity of $F$ and Equation (24).

Since $L$ acts simply transitively on each $X_s$, the stabiliser $L_x$ of every $x \in X_s$ is trivial, hence the Siegel weight $w_{L,n}(x)$ is constant, equal to $\frac{1}{\text{vol}(L(Z)) L_{s,X} \left[ A_s \right]}$. By Theorem 1 and Equation (23), there exist $\delta > 0$, that we may assume to be in $[0,1 - \frac{1}{n}]$, and $c > 0$ such that, as $t \geq 0$ and $t \to +\infty$,

$$\sum_{s \in [0,t]} N_s^{(1)} = c e^t + O(e^{t(1-\delta)}) .$$

For every $r \geq F(v_0) + 1$, by setting $t = \log \frac{r}{F(v_0)} \geq 0$ and by using the change of variables $k = e^s F(v_0)$ (see Equation (24)), we have, with $\Sigma_k = F^{-1}(k) \cap \mathbb{Z}^n$ and $\zeta$ Riemann’s zeta function,

$$\sum_{k \leq F(v_0), r} \text{Card}(L(Z) \setminus \Sigma_k) = \sum_{s \in [0,t]} \text{Card}(L(Z) \setminus X_s(Z)) = \sum_{s \in [0,t]} \sum_{p=1}^{+\infty} N_s^{(p)} = \sum_{p=1}^{+\infty} \sum_{s \leq 0} N_s^{(1)} s^{-\ln(p^n)} = \sum_{p=1}^{+\infty} c p^{-n} e^t + O(p^{n \delta - 1}) e^{t(1-\delta)}$$

$$= c \zeta(n) e^t + O(e^{t(1-\delta)}) = \frac{c \zeta(n)}{F(v_0)} r + O(r^{1-\delta}) .$$

Note that $\sum_{k \in \min \{1,F(v_0)\}, \max \{1,F(v_0)\}} \text{Card}(L(Z) \setminus \Sigma_k)$ is finite. The result follows.

### 3.2 Counting inequivalent integral points on hyperplane sections of affine quadratic surfaces

Let $n \geq 3$, let $q : \mathbb{C}^n \to \mathbb{C}$ with $q(x) = \sum_{i=1}^n q_{ij} x_i x_j$ for every $x = (x_1, \ldots, x_n)$ be a nondegenerate quadratic form in $n$ variables with coefficients $q_{ij}$ in $\mathbb{Q}$, and let $\ell : \mathbb{C}^n \to \mathbb{C}$ with $\ell(x) = \sum_{i=1}^n \ell_i x_i$ for every $x = (x_1, \ldots, x_n)$ be a nonzero linear form in $n$ variables with coefficients $\ell_i$ in $\mathbb{Q}$.
The aim of this section is to count the number of orbits of integral points on the sections, by the hyperplanes parallel to the kernel of \( \ell \), of the isotropic cone \( q^{-1}(0) \) of \( q \).

For \( K = \mathbb{R} \) or \( \mathbb{Q} \), recall that \( q \) is isotropic (or indefinite when \( K = \mathbb{R} \)) over \( K \) or represents 0 over \( K \) if there exists \( x \in K^n - \{0\} \) such that \( q(x) = 0 \), and that \( q \) is anisotropic over \( K \) otherwise. For instance, \( x^2 + 2y^2 - 7z^2 \) is anisotropic over \( \mathbb{Q} \), but indefinite over \( \mathbb{R} \). By A. Meyer’s 1884 result (see for instance [Ser, page 77]), if \( n \geq 5 \), then \( q \) is isotropic over \( \mathbb{Q} \) if and only if \( q \) is indefinite over \( \mathbb{R} \).

**Proof of Corollary 3.** In order to apply Theorem 15 (2), let us first define the objects appearing in its statement.

Let \( G = O_q \) be the orthogonal group of the nondegenerate rational quadratic form \( q \), which is a connected semisimple linear algebraic group defined over \( \mathbb{Q} \), hence is reductive without nontrivial \( \mathbb{Q} \)-characters. Let \( V = \mathbb{C}^n \) and let \( \rho : G \to \text{GL}(V) \) be the monomorphism mapping a matrix \( x \) to the linear automorphism of \( V \) whose matrix in the canonical basis is \( x \), which is an irreducible rational representation over \( \mathbb{C} \). Let \( \Lambda = \mathbb{Z}^n \), which is a \( \mathbb{Z} \)-lattice in \( V(\mathbb{Q}) \) invariant under \( G(\mathbb{Z}) \). To simplify the notation, we denote \( \rho(g)v = gv \) for every \( g \in G \) and \( v \in V \).

Since \( q \) is assumed to be isotropic over \( \mathbb{Q} \), there exists \( v_0 \) in \( \Lambda - \{0\} \) such that \( q(v_0) = 0 \) and we assume that \( \ell(v_0) \geq 0 \) up to replacing \( v_0 \) by \(-v_0\). Since the restriction of \( q \) to the kernel of \( \ell \) is assumed to be anisotropic over \( \mathbb{Q} \), we have \( \ell(v_0) > 0 \). Let \( P \) be the stabiliser in \( G \) of the line generated by \( v_0 \), which is a maximal (proper) parabolic subgroup of \( G \) defined over \( \mathbb{Q} \) since this line is isotropic. Let \( B = (e_1, \ldots, e_n) \) be a basis of \( V \) over \( \mathbb{Q} \) such that \( e_1 = v_0 \), \((e_1, e_2)\) is a standard basis of a hyperbolic plane over \( \mathbb{Q} \) for \( q \), which is orthogonal for \( q \) to the vector subspace \( V' \) generated by \( B' = (e_3, \ldots, e_n) \). In particular, the matrix of \( q \) in the basis \( B \) is \( Q = \begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & Q' \end{pmatrix} \) with \( Q' \) the (rational symmetric) matrix in the basis \( B' \) of the restriction \( q' \) of \( q \) to \( V' \). Denoting in the same way a vector \( v \) (resp. \( u \)) of \( V \) (resp. \( V' \)) and the column vector of its coordinates in \( B \) (resp. \( B' \)), we have \( q(v) = {^t}vQv \) (resp. \( q'(u) = {^t}uQ'u \)). With \( I_k \) the identity \( k \times k \) matrix and \( s \in \mathbb{R} \),
define
\[ a_s = \begin{pmatrix} e^s & 0 & 0 \\ 0 & e^{-s} & 0 \\ 0 & 0 & I_{n-2} \end{pmatrix}, \quad \mathbf{A} = \left\{ \begin{pmatrix} a & 0 & 0 \\ 0 & a^{-1} & 0 \\ 0 & 0 & I_{n-2} \end{pmatrix} : a \in \mathbb{C}^* \right\}, \]
\[ \mathbf{M} = \left\{ \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & m \end{pmatrix} : m \in \mathcal{O}_q \right\} \quad \text{and} \quad \mathbf{U} = \left\{ \begin{pmatrix} 1 - q'(u)/2 & -t u Q' \\ 0 & 1 & 0 \\ 0 & u & I_{n-2} \end{pmatrix} : u \in \mathcal{V}' \right\}. \]

It is easy to check that \( \mathbf{P} = \mathbf{A} \mathbf{M} \mathbf{U} \) is a relative Langlands decomposition of \( \mathbf{P} \), that the identity component of \( \mathbf{A}(\mathbb{R}) \) is the one-parameter subgroup \( (a_s)_{s \in \mathbb{R}} \), and that the stabiliser of \( v_0 = e_1 \) in \( \mathbf{G} \) is exactly \( \mathbf{M} \mathbf{U} \). With \( \mathfrak{U} \) the Lie algebra of \( \mathbf{U}(\mathbb{R}) \), an immediate computation gives (since \( n \geq 3 \))
\[ \lambda = \log \det(\text{Ad} a_1)_{\mathfrak{U}} = n - 2 > 0. \]  

We denote by \( \mathbf{L} = \{ g \in \mathbf{G} : \ell \circ g = \ell \} \) the stabiliser of \( \ell \) in \( \mathbf{G} \), which is a linear algebraic group defined over \( \mathbb{Q} \). Let \( \mathbf{W} \) be the kernel of \( \ell \) and \( \mathbf{W}^\perp \) be its orthogonal for \( q \). Since \( q_{\mathbf{W}} \) is assumed to be nondegenerate, \( \mathbf{W}^\perp \) is a line, \( \mathbf{V} = \mathbf{W}^\perp \oplus \mathbf{W} \), and the bloc matrix of \( q \) in this decomposition is diagonal.

Let us now check in the next lemma that the hypotheses of Theorem 15 are satisfied by these objects.

**Lemma 21** (1) The linear algebraic group \( \mathbf{L} \) is reductive and anisotropic over \( \mathbb{Q} \).

(2) For every \( s \in \mathbb{R} \), if \( k = e^s \ell(v_0) \) and \( \mathbf{X}_s = \mathbf{L} a_s v_0 \), then \( \mathbf{X}_s = \{ v \in \mathbf{V} : q(v) = 0, \ell(v) = k \} \). In particular, \( \mathbf{X}_s \) is Zariski-closed in \( \mathbf{V} \).

(3) The subset \( \mathbf{L} \mathbf{P} \) is Zariski-open in \( \mathbf{G} \).

**Proof.** (1) For every \( g \in \text{GL}(\mathbf{V}) \), if \( \ell \circ g = \ell \), then \( g \) preserves \( \mathbf{W} \). If furthermore \( g \in \mathbf{G} = \mathcal{O}_q \), then \( g \) preserves \( \mathbf{W}^\perp \). Since \( \mathbf{W}^\perp \) is a line, there exists \( \lambda \in \mathbb{C} \) such that \( g \) acts by \( x \mapsto \lambda x \) on \( \mathbf{W}^\perp \). As \( \ell|_{\mathbf{W}^\perp} \) is nonzero and \( g \) preserves \( \ell \), we have \( \lambda = 1 \). Hence the elements of \( \mathbf{L} \) are exactly the elements of \( \text{GL}(\mathbf{V}) \) whose bloc matrix in the decomposition \( \mathbf{V} = \mathbf{W}^\perp \oplus \mathbf{W} \) has the form \( \begin{pmatrix} 1 & \lambda g' \\ 0 & 1 \end{pmatrix} \) with \( g' \in \mathcal{O}_{q_{\mathbf{W}}} \). In particular, the linear algebraic group \( \mathbf{L} \), isomorphic over \( \mathbb{Q} \) to the orthogonal group of the nondegenerate rational quadratic form \( q_{\mathbf{W}} \), is semisimple hence reductive.

It is well-known (see for instance [Bor1][BJ, page 270]) that the \( \mathbb{Q} \)-rank of the orthogonal group \( \mathcal{O}_{q''} \) of a nondegenerate rational quadratic form \( q'' \) is zero (or equivalently that \( \mathcal{O}_{q''} \) is anisotropic over \( \mathbb{Q} \)) if and only if \( q'' \) does not represents \( 0 \) over \( \mathbb{Q} \). For instance, this follows from the fact that the spherical Tits building over \( \mathbb{Q} \) of \( \mathcal{O}_{q''} \) is the building of isotropic flags over \( \mathbb{Q} \). Hence by assumption, \( \mathbf{L} \) is anisotropic over \( \mathbb{Q} \).

(2) Note that by the definition of \( a_s \), we have \( a_s v_0 = e^s v_0 \), hence by the linearity of \( \ell \), we may assume that \( s = 0 \). Recall that \( q(v_0) = 0 \) and \( \ell(v_0) > 0 \). By the definition of \( \mathbf{L} \), the orbit \( \mathbf{X}_0 = \mathbf{L} v_0 \) is contained in \( \{ v \in \mathbf{V} : q(v) = 0, \ell(v) = \ell(v_0) \} \). To prove the opposite inclusion, write \( v = v' + v'' \) the decomposition of any \( v \in \mathbf{V} \) in the direct sum \( \mathbf{V} = \mathbf{W}^\perp \oplus \mathbf{W} \). If \( \ell(v) = \ell(v_0) \) and \( q(v) = 0 \), then \( v' = v_0' \) and \( q(v'') = -q(v') = -q(v_0') \), and in particular \( q(v'') = q(v_0'') \). By Witt’s theorem, there exists \( g' \in \mathcal{O}_{q_{\mathbf{W}}} \) such that \( v'' = g' v_0'' \). Hence the linear transformation of \( \mathbf{V} \) which is the identity on \( \mathbf{W}^\perp \) and is equal to \( g' \) on \( \mathbf{W} \), is an element of \( \mathbf{L} \) sending \( v = v' + v'' \) to \( v_0 = v_0' + v_0'' \). The second assertion follows.
(3) The algebraic group $G = O_q$ acts transitively on the projective variety of isotropic lines in $V$, the stabiliser of the line generated by $v_0$ being $P$ by definition. As we have seen in (2), the orbit under $L$ of the line generated by $v_0$ is hence the Zariski-open subset of $G/P$ consisting of the isotropic lines not contained in $W$. The last claim of Lemma 21 follows.

To conclude the proof of Corollary 3, we relate the two counting functions in the statements of Corollary 3 and Theorem 15 (2). Let $L = L(\mathbb{R})_0$ and $\Gamma = G(\mathbb{R})_0 \cap G(\mathbb{Z})$.

We have $\ell(v_0) > 0$ by the definition of $v_0$. For every $r \geq \ell(v_0) + 1$, let $t = \ln \frac{r}{\ell(v_0)} > 0$. With $\Sigma_k$ as in the statement of Corollary 3, using the change of variables $k = e^t\ell(v_0)$ and Lemma 21 (2), by the definition of the modified Siegel weights in Equation (2), we have

$$
\sum_{k \in [\ell(v_0), r]} \sum_{[u] \in (L(\mathbb{Z}) \cap L) \setminus \Sigma_k} \text{vol} \left( (L_u(\mathbb{Z}) \cap L) \setminus (L_u \cap L) \right) = \\
\text{vol} \left( (L \cap \Gamma) \setminus L \right) \sum_{s \in [0, t]} \sum_{[u] \in (L(\mathbb{Z}) \cap L) \setminus X_s \cap \Lambda^\text{prim}} w'_{L, \rho_L}(u). 
$$

(26)

By Theorem 15 (2) and Equation (25), there exist $c, \delta > 0$ such that as $t \to +\infty$, the quantity (26) is equal to

$$
c e^{(n-2)t} + o \left( e^{(n-2-\delta)t} \right) = \frac{c}{\ell(v_0)^{n-2}} r^{n-2} + O \left( r^{n-2-\delta} \right).
$$

Note that $\sum_{k \in [\min(1, \ell(v_0)), \max(1, \ell(v_0))] \setminus \{1 \}} \sum_{[u] \in (L(\mathbb{Z}) \cap L) \setminus \Sigma_k} \text{vol} \left( (L_u(\mathbb{Z}) \cap L) \setminus (L_u \cap L) \right)$ is finite. This concludes the proof of Corollary 3. □

Remarks

(1) If $n \geq 6$, since $q$ is isotropic over $\mathbb{Q}$ and the restriction of $q$ to the kernel of $\ell$ is anisotropic over $\mathbb{Q}$, then the signature of $q$ over $\mathbb{R}$ is $(1, n-1)$ or $(n-1, 1)$, and $L(\mathbb{R})$ is compact (see the above picture on the right); hence $L(\mathbb{Z})$ is finite, and our result allows to count integral points on the quadric hypersurface $q^{-1}(0)$ (see the references given in the introduction for related works).

(2) If $n \geq 4$, then we have a result similar to Corollary 3 where we consider all the integral points and not only the primitive ones: under the other assumptions of Corollary 3 and with $c$ as above, we have, for every $r \geq 1$ with $r \to +\infty$,

$$
\sum_{k \in [1, r]} \sum_{[u] \in (L(\mathbb{Z}) \cap L) \setminus (q^{-1}(0) \cap L(\mathbb{Z}))} \text{vol} \left( (L_u(\mathbb{Z}) \cap L) \setminus (L_u \cap L) \right) = \\
= \frac{c(2n - 2)}{\ell(v_0)^{n-2}} r^{n-2} + O \left( r^{n-2-\delta} \right).
$$

The proof is similar to the one at the end of Section 3.1. For every $s \in \mathbb{R}$ and $p \in \mathbb{N} - \{0\}$, we denote by $A_s^{(p)}$ the set of integral points of $X_s$ whose greatest common divisor of their coefficients is $p$. We note that by Lemma 21 (2), the map from $A_s^{(p)}$ to $A_{s-Lnp}^{(1)}$ defined by $x \mapsto \frac{x}{p}$ is a bijection such that $L_x = L_{x'}$ for every $x \in A_s^{(p)}$. Hence with

$$
N_s^{(p)} = \sum_{[u] \in (L(\mathbb{Z}) \cap L) \setminus A_s^{(p)}} \text{vol} \left( (L_u(\mathbb{Z}) \cap L) \setminus (L_u(\mathbb{R}) \cap L) \right),
$$

we have \( N_s^{(p)} = N_{s-in,p} \) and

\[
\sum_{[u] \in (L) \cap L} \frac{1}{(q-1)(0) \cap (k) \cap \mathbb{Z}^n}) \text{ vol } ((L_u \cap L) \backslash (L_u \cap L) = \sum_{p=1}^{\infty} N_s^{(p)},
\]

and one concludes as in the end of Section 3.1.

When \( n = 3 \), the same argument gives

\[
\sum_{k \in [1, r]} \sum_{[u] \in (L) \cap L} \frac{1}{(q-1)(0) \cap (k) \cap \mathbb{Z}^n}) \text{ vol } ((L_u \cap L) \backslash (L_u \cap L) = \frac{c}{\ell(v_0)} r \log r + O(r).
\]

### 3.3 Counting inequivalent integral points of given norm in central division algebras

Let \( n \geq 2 \), let \( D \) be a central simple algebra over \( \mathbb{Q} \) of dimension \( n^2 \), let \( N : D \to \mathbb{Q} \) be its reduced norm, and let \( \mathcal{O} \) be an order in \( D \) (that is, a finitely generated \( \mathbb{Z} \)-submodule of \( D \), generating \( D \) as a \( \mathbb{Q} \)-vector space, which is a unitary subring). We refer for instance to [Rei] and [PR, Chap. I, §1.4]) for generalities. The aim of this section is to use our main result to deduce asymptotic counting results of elements of \( \mathcal{O} \) (modulo units) of given norm. We note that this result can be also deduced by elementary methods (as for the first example) of fundamental domain for the action of unit groups on a level set of the norm, as well as from the analytic continuation (established in [SS]) of the zeta function associated to the corresponding prehomogeneous vector space.

**Corollary 22** If \( D \) is a division algebra over \( \mathbb{Q} \), then there exist \( c = c(D, \mathcal{O}) > 0 \) and \( \delta = \delta(D) > 0 \) such that, for every \( r \geq 1 \) with \( r \to +\infty \),

\[
\text{Card } \mathcal{O} \times \{ x \in \mathcal{O} : 1 \leq |N(x)| \leq r \} = c \cdot r^n \left( 1 + O(r^{-\delta}) \right).
\]

**Proof.** In order to apply Theorem 1, let us first define the objects appearing in its statement.

Let \( V \) be the vector space over \( \mathbb{Q} \) such that \( V(K) = D \otimes_{\mathbb{Q}} K \) for every characteristic zero field, with the integral structure such that \( \Lambda = V(\mathbb{Z}) = \mathcal{O} \), which is (for the extended multiplication) a central simple algebra over \( \mathbb{C} \). Let \( D^1 \) be the group of elements of (reduced) norm \( \pm 1 \) in \( V \).

We take \( G = \text{SL}(V) \) (which is connected, simply connected, semisimple, defined over \( \mathbb{Q} \), hence reductive without nontrivial \( \mathbb{Q} \)-characters) and \( \rho \) the inclusion of \( G \) in \( \text{GL}(V) \) (which is an irreducible rational representation). To simplify the notation, we denote \( \rho(g)v = gv \) for every \( g \in G \) and \( v \in V \).

Let \( L \) be the algebraic subgroup of \( G \) which is the image of \( D^1 \) into \( G \) by the (left) regular representation \( d \mapsto \{ v \mapsto dv \} \). Note that the linear algebraic groups \( L \) and \( D^1 \) are defined over \( \mathbb{Q} \) and are isomorphic by this representation. We have

\[
L(\mathbb{Z}) = D^1 \cap \mathcal{O} = \mathcal{O}^\times.
\]

We take \( v_0 \in V \) to be the identity element in \( D \). The stabiliser of the line \( \mathbb{C}v_0 \) in \( G \) is a (maximal) parabolic subgroup \( P \) of \( G \) defined over \( \mathbb{Q} \). We note that \( \text{dim}(P) = \text{dim}(D)^2 - \text{dim}(D) - 1 \) and \( \text{dim}(L) = \text{dim}(D) - 1 \). We have a relative Langlands decomposition
\( \mathbf{P} = \mathbf{A} \mathbf{M} \mathbf{U} \) with \( \mathbf{M} \mathbf{U} \) the stabiliser of \( v_0 \) in \( \mathbf{G} \), and we may write \( \mathbf{A}(\mathbb{R})_0 = (a_s)_{s \in \mathbb{R}} \) such that \( a_s v_0 = \hat{e}^s v_0 \). An easy computation gives

\[
\lambda = \log \det(\operatorname{Ad} a_1)_{\mathcal{U}} = n > 0.
\] (28)

Let us now check that the hypotheses of Theorem 1 are satisfied by these objects.

We claim that the group \( \mathbf{L} \cap \mathbf{P} \) is finite. The action of this group on \( v_0 \) defines a \( \mathbb{Q} \)-character of \( \mathbf{L} \cap \mathbf{P} \). Since \( \mathbf{L} \cong \mathbf{D}^1 \) is anisotropic over \( \mathbb{Q} \) (see for instance [PR, Chap. II, §2.3]), this character must be trivial on \( \mathbf{L} \cap \mathbf{P})_0 \), and \( \mathbf{L} \cap \mathbf{P})_0 v_0 = v_0 \). Since \( \text{Stab}_{\mathbf{L}}(v_0) = \{e\} \), it follows that \( \mathbf{L} \cap \mathbf{P})_0 = \{e\} \), which proves the claim. Comparing dimensions, we deduce that \( \mathbf{L} \mathbf{P} \) is Zariski-open in \( \mathbf{G} \).

For every \( s \in \mathbb{R} \), we have

\[
X_s = \mathbf{L} a_s v_0 = \hat{e}^s \mathbf{L} v_0 = \hat{e}^s \mathbf{D}^1.
\] (29)

Hence \( X_s \) is Zariski-closed in \( \mathbf{V} \).

To conclude the proof of Corollary 22, we relate the two counting functions in the statements of Corollary 22 and Theorem 1.

Since \( \mathbf{L} \) acts simply transitively on the orbit of \( v_0 \), the Siegel weights are constant, equal to \( \frac{1}{\text{vol}(\mathbf{L}(\mathbb{Z}) \setminus \mathbf{L}(\mathbb{R}))} \). For every \( k \in \mathbb{N} - \{0\} \), denote by \( \mathcal{O}^{(k)} \) the subset of nonzero elements of \( \mathcal{O} \) whose greatest common divisor of their coefficients in a \( \mathbb{Z} \)-basis of \( \mathcal{O} \) is \( k \). In particular, since the norm is a homogeneous polynomial of degree \( n \) and by Equation (29), we have

\[
X_s \cap \Lambda_{\text{prim}} = \{ x \in \mathcal{O}^{(1)} : N(x) = e^s \}.
\]

Note that the map \( x \mapsto \frac{x}{k^n} \) is a bijection from \( \mathcal{O}^{(k)} \) to \( \mathcal{O}^{(1)} \). Hence, using Equation (27) and Theorem 1, there exist \( \delta > 0 \), that we may assume to be in \( \]0,1\[ \), and \( c > 0 \) such that, as \( r \geq 1 \) and \( r \to +\infty \),

\[
\begin{align*}
\text{Card} \mathcal{O} \setminus \{ x \in \mathcal{O} : 1 \leq |N(x)| \leq r \} & = \sum_{k=1}^{+\infty} \text{Card} \mathcal{O} \setminus \{ x \in \mathcal{O}^{(k)} : 1 \leq |N(x)| \leq \frac{r}{k^n} \} \\
& = \sum_{k=1}^{+\infty} \text{Card} \mathcal{O} \setminus \{ x \in \mathcal{O}^{(1)} : 1 \leq |N(x)| \leq \frac{r}{k^n} \} \\
& = \sum_{k=1}^{+\infty} \sum_{0 \leq s \leq \log \frac{r}{k^n}} \text{Card} (\mathbf{L}(\mathbb{Z}) \setminus (X_s \cap \Lambda_{\text{prim}})) \\
& = \sum_{k=1}^{+\infty} c \left( \frac{r}{k^n} \right)^n \left( 1 + O \left( \left( \frac{r}{k^n} \right)^{-\delta} \right) \right) \\
& = c \zeta(n^2) r^n \left( 1 + O(r^{-\delta}) \right).
\end{align*}
\]

This ends the proof of Corollary 22.

\[\square\]
