ABSTRACT

Background: Identification of tissue hypoxia and hypoperfusion plays an important role in the management of critically ill patients. Although the venous-arterial PCO₂ difference (ΔPCO₂) cannot serve as a marker of tissue hypoxia, it is considered a marker of the adequacy of venous blood flow (Cardiac output). The present study aimed to evaluate the role of venous-arterial PCO₂ gradient in prediction of outcome in septic patients admitted to ICU.

Methods: 100 adult patients fulfilled the criteria of severe sepsis or septic shock admitted to Emergency Intensive Care Unit, were divided in two groups according to ΔPCO₂. The high ΔPCO₂ group (ΔPCO₂ > 6 mmHg) included 52 patients and the normal ΔPCO₂ (ΔPCO₂ ≤ 6 mmHg) included 48 patients. Clinical scoring systems were recorded. Clinical outcome including organ dysfunction and mortality was recorded.

Results: The high ΔPCO₂ group showed significant lower blood glucose level (p = 0.038) than the normal ΔPCO₂ group. Serum lactate, heart rate, and APACHE score were significantly higher in high ΔPCO₂ group than normal ΔPCO₂ group, (p = 0.012, 0.013, and 0.020, respectively). As regard to the clinical outcome, patient mortality was significantly higher (p = 0.042) in high ΔPCO₂ group than normal ΔPCO₂ group and the number of organ dysfunction was higher in high ΔPCO₂ group than normal ΔPCO₂ group but not reached a significant level (p = 0.625).

Conclusions: ΔPCO₂ is a reliable index for early prediction of clinical outcome including organ dysfunction and mortality in patients with sepsis and septic shock.

1. Introduction

Identification of tissue hypoxia and hypoperfusion plays an important role in the management of critically ill patients during early resuscitation [1].

Resuscitation may be guided by central venous oxygen saturation (ScvO₂) as an indicator of tissue hypoxia. Significant fluctuations in ScvO₂ may occur during sepsis. However, persistent tissue hypoperfusion caused by microcirculatory and mitochondrial failure may occur in the presence of normal or increased ScvO₂ [2].

ΔPCO₂ is the difference between the partial pressure of CO₂ in mixed venous blood (PvCO₂) and arterial blood. It represents only a fraction of arterial and venous CO₂ content (CaCO₂ and CvCO₂) respectively. However, as the relationship between partial pressure and content of CO₂ is almost linear under normal physiological conditions, Pco₂ can be taken as a measure of CO₂. At the cellular level, CO₂ is a normal terminal product of oxidative metabolism. Thus, in the absence of a shunt, CO₂ in the efferent venous blood must be higher than in the afferent arterial blood [3].

According to the Fick equation, CO₂ excretion (equivalent to CO₂ production in a steady state) equals the product of cardiac output (CO) and the veno-arterial difference in CO₂ content (CaCO₂–CvCO₂). Accordingly, the ΔPCO₂ = VCO₂ × k/CO, k is assumed to be constant, and ΔPCO₂ is linearly related to CO₂ production and inversely related to CO. Therefore, if cardiac output is low, ΔPCO₂ is expected to be abnormally high (More than 6 mmHg) [4].

Global indices of tissue perfusion include lactate and central venous oxygen saturation (ScvO₂). Although ΔPCO₂ cannot serve as a marker of tissue hypoxia, it can be considered as a marker of the adequacy of venous blood flow (Cardiac output) to remove the total CO₂ produced by the peripheral tissues [5]. ΔPCO₂ has also been described in patients with sepsis, cardiogenic shock, acute myocardial infarction, and congestive heart failure, as well as cardiac arrest following CPR and heart surgery [6].

Interestingly, ΔPCO₂ has recently been proposed as a useful tool for goal-directed therapy (GDT) in ICU-septic patients to identify persistent hypoperfusion when a ScvO₂ > 70% has been reached as oxygen consumption (VO₂) is impaired as a consequence of mitochondrial dysfunction in sepsis [7]. Experimental models have shown that in toxemia, venous...
hypercapnia is a more significant contributor to the increase in the veno-arterial CO\textsubscript{2} gradient than arterial CO\textsubscript{2} values [8]. This study aimed to evaluate the role of ΔPCO\textsubscript{2} gradient in prediction of outcome in septic patients admitted to ICU.

2. Patients and methods

2.1. Study design

A prospective observational study was performed at the Emergency Intensive Care Unit (ICU) of Benha University hospital from August 2018 to April 2020. The study included 100 adult critically ill patients admitted to the intensive care unit after approval by the local Ethical Committee and a written informed consent was obtained from patient’s relatives.

2.2. Inclusion and exclusion criteria

Adult patients were admitted to the ICU with a length of stay ≥ 24 hours and fulfilled the criteria of severe sepsis or septic shock. We have excluded patients below 18 years, patients admitted with a length of stay <24 h, patients with chronic obstructive pulmonary disease (COPD) were excluded.

2.3. Study groups and data

Radial arterial cannula was inserted for arterial blood gases sampling and internal jugular central venous pressure (CVP) catheter was inserted for central venous blood gases sampling. Patients were divided and compared on the basis of ΔPCO\textsubscript{2} values measured on admission into two groups: High ΔPCO\textsubscript{2} group (ΔPCO\textsubscript{2} > 6 mmHg) and normal ΔPCO\textsubscript{2} group (ΔPCO\textsubscript{2} ≤ 6 mmHg).

On admission, patient’s demographic data were recorded in both groups, full detailed history taking, complete clinical examination and full laboratory investigations (urea, creatinine, Na, K, complete blood count (CBC), alanine transaminase (ALT), aspartate transaminase (AST), bilirubin, albumin, serum lactate, INR (International normalized ratio), and random blood sugar were done. Hemodynamic parameters including (mean arterial blood pressure, heart rate, respiratory rate), clinical scoring systems including Glasgow coma scale (GCS), Acute Physiology and Chronic Health Evaluation (APACHE II), Sequential Organ Failure Assessment (SOFA) were recorded. Laboratory investigations, hemodynamic parameters, SOFA and GCS scoring systems were daily repeated for patient follow up according to the length of ICU stay. The number of mechanically ventilated patients and duration of ventilation and ICU stay were also recorded. Clinical outcomes including organ dysfunction and 28-day mortality rate was recorded. Delta PCO\textsubscript{2} was correlated to laboratory investigations, GCS, APACHE II, SOFA scores, duration of mechanical ventilation and number of organ dysfunction.

A Consort flow chart was shown in Figure 1.

3. Statistical analysis

The collected data was tabulated and analyzed using SPSS version 16 software (SPSS Inc, Chicago, ILL Company). Categorical data were presented as number and percentages, Chi square (χ\textsuperscript{2}) test was used to analyze them. Quantitative data were tested for normality using Kolmogorov Smirnov test assuming normality at P > 0.05. Normally distributed variables were expressed as mean ± standard deviation and analyzed by Student “t” for 2 independent groups. Correlations were assessed by Person’s correlation coefficient (r). P ≤ 0.05 was considered significant.

3.1. Sample size calculation

MedCalc software version 16.1(© 1993–2016 MedCalc Software, www.medcalc.org) was used to calculate the required sample size using the mean values of SOFA day1 among the studied normalΔPCO\textsubscript{2} group (9.5 ± 2.8) and the high ΔPCO\textsubscript{2} group (12 ± 3.9) groups according to Araujo et al. [9] as follows:

- Level of significance (type I error) = 0.05,
- Type II error (1-level of power) = 0.2
- Difference in means = 2.5
- SD in group1 = 2.8
- SD in-group 2 = 3.9

Therefore, the least sample size is 60 subjects, 30 in each group.

4. Results

The study initially included 120 patients assessed for eligibility, 20 patients were excluded (12 patients not meeting inclusion criteria, 8 patients declined to participate). The study finally included 100 patients divided according to the ΔPCO\textsubscript{2} value into two groups, the normal ΔPCO\textsubscript{2} group included 42 patients and the high ΔPCO\textsubscript{2} group included 58 patients. These data were illustrated in the consort flow chart.

As regard to patient demographic data, there was no significant difference between both groups regarding age (p = 0.268) or sex (p = 0.768). The data are shown in Table 1.

According to the cause of admission, the high ΔPCO\textsubscript{2} group included more patients with severe sepsis and septic shock than the normal ΔPCO\textsubscript{2} group with a significant p value = 0.016. However, the number of mechanically ventilated patients were similar in both studied groups (p value = 0.551) as shown in Table 2.
Table 1. The patients’ demographic data in both studied groups.

|                      | Normal ΔPCO₂ group (N = 42) | High ΔPCO₂ group (N = 58) | P value |
|----------------------|------------------------------|---------------------------|---------|
| Age Mean ± SD        | 60.9 ± 14.9                  | 58.4 ± 19.3               | 0.268   |
| Sex M/F (%)          | 14/28 (33.3/66.7%)           | 24/34 (41.4/58.6%)        | 0.766   |

Significant p value < 0.05

Table 2. The causes of patients’ admission to ICU and number of patients on mechanical ventilation.

|                      | Normal ΔPCO₂ group (N = 42) | High ΔPCO₂ group (N = 58) | χ²     | P value |
|----------------------|------------------------------|---------------------------|--------|---------|
| Severe sepsis        | 36                           | 30                        | 51.7   | 6.271   | 0.016   |
| Septic shock         | 6                            | 14.3                      | 28     | 48.3    | 0.006   |
| Number of patients on mechanical ventilation | 18                           | 42.9                      | 18     | 31.0    | 0.739   | 0.551   |

Significant p value < 0.05

Regarding comorbidities, there were 28 (56.0%) diabetic patients, 32 (64%) hypertensive patients, 27 (54%) patients with cardiovascular insults, 18 (36%) patients with chronic kidney disease (CKD), 5(10%) patients with chronic lung disease (CLD), 10 (20%) patients with neurological insults, 31 (62%) patients with severe respiratory disease, 12 (24%) patients with malignancy and 3 (6%) patients with thyroid diseases. There was
insignificant statistical difference (p = 0.28) in the distribution of co-morbidities between both groups of ΔPCO₂ (data was not shown).

As regard to the duration of mechanical ventilation, the duration of ICU stays, the need for vasopressor drugs, laboratory investigations, ICU scoring and patients mortality.

Duration of mechanical ventilation and ICU stay was recorded in both groups; the duration was longer in the high group of ΔPCO₂ than in the normal group with no significant statistical differences.

The heart rate was significantly higher (p = 0.013) in the high ΔPCO₂ group than the normal group (110.5 ± 13.5 versus 95.3 ± 20.0) beat/min. The mean arterial blood pressure was lower in the high ΔPCO₂ group than the normal group (71.2 ± 31.8 versus 84.6 ± 16.2) mmHg with insignificant statistical difference (p = 0.058). The need for vasopressor drugs was higher in the high ΔPCO₂ group than the normal group (63.8% versus 57.1%) with insignificant statistical difference (p value = 0.152).

As regard laboratory investigations, there was insignificant statistical difference between both groups of ΔPCO₂ in all parameters except for blood glucose and serum lactate level. Blood glucose was significantly lower (p = 0.038) in the high ΔPCO₂ group than the normal group (201.9 ± 85.6 versus 270.7 ± 119.3) mg/dl. Serum lactate was significantly higher (p = 0.012) in the high ΔPCO₂ group than the normal group (3.6 ± 1.5 versus 1.8 ± 0.7) mmol/L.

ICU scoring systems including GCS, APACHE, and SOFA score systems were recorded. There was insignificant statistical difference between both groups except for the APACHE score that was significantly higher (P value = 0.020) in the high ΔPCO₂ group than the normal one (24.3 ± 7.5 versus 19.9 ± 5.4).

The 28- day mortality rate was significantly higher (p = 0.042) in high ΔPCO₂ group than normal ΔPCO₂ group. All these data are shown in Table 3.

As regard to the organ dysfunction in the ICU, it was higher in high ΔPCO₂ group than normal ΔPCO₂ group with insignificant statistical difference (p value = 0.625), as shown in Table 4.

The ΔPCO₂ was correlated with laboratory investigations, GCS, APACHE II, SOFA scores, duration of mechanical ventilation, ICU stay, and organ dysfunction.

We have found that serum k level, serum Na level, blood glucose level, liver enzymes, albumin, and platelets, were inversely proportional to ΔPCO₂ value.

On the other hand, urea, creatinine, bilirubin, hemoglobin, hematocrit, total leucocytic count, INR, arterial pH, were directly proportional to ΔPCO₂ value. All these correlations were statistically insignificant except serum k level, as shown in Table 5.

The duration of mechanical ventilation and the number of organ dysfunction, APACHE II and SOFA

### Table 3. Comparison of the duration of mechanical ventilation, ICU stay, vital signs, some laboratory investigation and ICU scoring system on the time of ICU admission in both studied groups.

|                   | Normal ΔPCO₂ group N = 42 | High ΔPCO₂ group N = 58 | P-value |
|-------------------|---------------------------|-------------------------|---------|
| Duration of mechanical ventilation (days) Mean ±SD | 6.7 ± 4.3 | 7.2 ± 5.1 | 0.470 |
| Duration of ICU stay (days) Mean ±SD | 14.4 ± 11.8 | 15.0 ± 7.3 | 0.350 |
| Heart Rate (beat/min) Mean ±SD | 95.3 ± 20.0 | 110.5 ± 13.5 | 0.013 |
| Mean Arterial Blood Pressure (mmHg) Mean ±SD | 84.6 ± 16.2 | 71.2 ± 31.8 | 0.058 |
| Number of patients who received vasopressor drugs (%) | 24 (57.1) | 37(63.8) | 0.152 |
| Respiratory Rate (breath/min) Mean ±SD | 22.8 ± 6.4 | 22.8 ± 8.8 | 0.999 |
| Glucose levels mg/dl Mean ±SD | 270.7 ± 119.3 | 201.9 ± 85.6 | 0.038 |
| Lactate level(mmol/L) Mean ±SD | 1.8 ± 0.7 | 3.6 ± 1.5 | 0.012 |
| Glasgow coma scale (GCS) Mean ±SD | 13.7 ± 2.5 | 11.9 ± 4.2 | 0.062 |
| APACHE score Mean ±SD | 19.9 ± 5.4 | 24.3 ± 7.5 | 0.020 |
| SOFA score, Mean ±SD | 8.6 ± 2.7 | 11.5 ± 4.3 | 0.031 |
| 28- day mortality number (%) | 12 (28.6%) | 40(69%) | 0.042 |

Significant p value < 0.05

### Table 4. Differences between the ΔPCO₂ groups regarding the number of organ dysfunction in ICU.

| Number of organs dysfunction | Normal ΔPCO₂ Group N = 42 | High ΔPCO₂ Group N = 58 | Total N = 100 | χ² | P-value |
|------------------------------|---------------------------|-------------------------|---------------|----|---------|
| 0                            | 4                         | 9.5                    | 3.4           | 6  | 6.0     | 3.487 | 0.625 |
| 1                            | 10                        | 23.8                   | 8             | 13.8| 18      | 18.0  | 0.350 |
| 2                            | 10                        | 23.8                   | 12            | 20.7| 22      | 22.0  | 0.350 |
| 3                            | 12                        | 28.6                   | 24            | 41.4| 36.0    | 36.0  | 0.350 |
| 4                            | 6                         | 14.3                   | 8             | 13.8| 14      | 14.0  | 0.350 |
| 5                            | 0                         | 0.0                    | 4             | 6.9 | 4       | 4.10  | 0.350 |

Significant p value < 0.05

### Table 5. The correlation between ΔPCO₂ values and some laboratory parameters.

| Parameter               | R     | P-value |
|-------------------------|-------|---------|
| Potassium               | -0.363| 0.010   |
| Sodium                  | -0.047| 0.744   |
| Creatinine              | 0.012 | 0.932   |
| Urea                    | 0.056 | 0.702   |
| Random blood sugar      | -0.249| 0.085   |
| Bilirubin               | 0.054 | 0.710   |
| ALT (Alanine transaminase) | -0.088| 0.547   |
| AST (Aspartate transaminase) | -0.092| 0.528   |
| Albumin                 | -0.153| 0.289   |
| Hb (Hemoglobin)         | 0.085 | 0.558   |
| TLC (Total leucocytic count) | 0.228| 0.110   |
| HCT (Hematocrit Percent) | 0.044 | 0.760   |
| PLT(Platelets)          | -0.021| 0.883   |
| INR                     | 0.026 | 0.855   |
| Arterial pH             | 0.197 | 0.171   |

Significant p value < 0.05
scores were directly proportional to ΔPCO₂ value. However, GCS was inversely proportional to ΔPCO₂. All these correlations were statistically insignificant except GCS and SOFA score as shown in Table 6.

### 5. Discussion

Shock is defined as global tissue hypoxia secondary to an imbalance between systemic oxygen delivery and oxygen demand. Hence, normal ScvO₂ values do not guarantee adequate tissue oxygenation and other circulatory parameters are needed to evaluate resuscitation efforts. The central venous-arterial carbon dioxide difference (pCO₂gap) can be considered as a marker of the adequacy of venous blood flow to remove the total CO₂ produced by the peripheral tissues [10]. The aim of this study was to evaluate the role of venous-arterial PCO₂ gradient in prediction of outcome in septic patients admitted to ICU.

Our findings were in line with physiological theory, which described an inverse curvilinear relation between cardiac output and PCO₂ gap, according to a modified Fick equation for a range of CO₂ production. Various studies have described such an inverse relationship between the delta PCO₂ gap and cardiac index in septic circulatory failure [11].

In the present study, 38% of admitted patients were males and 62% of patients were females, with no significant statistical difference between the two groups. The mean age for admitted patients was 60.9 ± 14.9 years for the normal group and 58.4 ± 19.3 years for the high ΔPCO₂ group with no significant statistical difference between both groups.

According to the cause of admission, 66% of admitted patients had severe sepsis and 34.0% had septic shock. The number of septic shock patients was significantly higher (P-value <0.05) in the high ΔPCO₂ group 28 (48.3%) than in the normal ΔPCO₂ group 6 (14.3%). Jamia et al. [12] explained the relationship between ΔPCO₂ and hypoperfusion by the fact that ΔPCO₂ is linearly related to CO₂ production that increases in shock due to the shift to anaerobic metabolism. and inversely related to cardiac output which significantly decreases in shock states.

Regarding the hemodynamics parameters in the studied groups, heart rate increased significantly (p-value of 0.013) in the high ΔPCO₂ group (mean = 110.5 ± 13.5) than in the normal one (mean = 95.3 ± 20.0). This is explained by the compensatory sympathetic stimulation which increases heart rate in hypoxic hypoperfused patients to maintain cardiac output and organ perfusion. The mean arterial blood pressure was lower in high ΔPCO₂ (71.2 ± 31.8) than normal one (84.6 ± 16.2) but not reached a significant level (p = 0.058). On admission, 57.1% of the normal group versus 63.8% of the high group required inotropic support without significant difference between both groups. The mean respiratory rate was almost equal between both groups with no significant difference. In agreement with the above-mentioned results, Arajuo et al. [9] detected insignificant difference in the mean arterial blood pressure and the requirement of inotropic support between both ΔPCO₂ groups.

Bitar et al. [11] detected a significant lower mean arterial blood pressure (p-value, 0.01) in high ΔPCO₂ group. The need for more vasopressors and IV fluid administration were significantly higher in high ΔPCO₂ group than the normal the ΔPCO₂ group (p value = 0.01 and 0.009, respectively).

At the time of admission, 36% of patients were mechanically ventilated and 64% of patients were not. We have found that the mean duration of mechanical ventilation increased in the high ΔPCO₂ group (7.2 ± 5.1 days) than in the normal one (6.7 ± 4.3 days) without a significant statistical difference in both groups. In addition, length of ICU stay was longer in high ΔPCO₂ than normal ΔPCO₂. Robin et al. supported these results [13].

The mean blood glucose level was significantly less (p = 0.038) in the high ΔPCO₂ group (201.9 ± 85.6) than in the normal group (270.7 ± 119.3). This can be explained by Randal et al. [14] who stated that under anaerobic conditions, accelerated anaerobic glycolysis leads to excessive lactic acid production (since pyruvate cannot be longer cleared by the Krebs cycle). This mechanism explains increased CO₂ production in hypoxic conditions. Another explanation is the relative adrenal insufficiency that occurs in septic shock and low flow states.

Regarding the clinical scoring systems in the ICU, the APACHE II score was significantly higher (p = 0.020) in the high ΔPCO₂ group (mean = 24.3 ± 7.5) than the normal ΔPCO₂ group (mean = 19.9 ± 5.4). This result was supported by Wang et al. [15] who reported significant positive correlation between ΔPCO₂ and APACHE II score (r = 0.377, p < 0.001). The SOFA score which reflects organ dysfunction and failures in the ICU, was significantly higher (p = 0.031) in the high ΔPCO₂ group than the normal group with a significant positive correlation with ΔPCO₂ (r = 0.283, p = 0.046). This was supported by Ospina-Tascon et al. [16] who found that the persistence of high ΔPCO₂ was associated with a higher 3 days SOFA score (P < 0.001). In

| Table 6. Correlation between ΔPCO₂ values and duration of mechanical ventilation, number of organ dysfunction and different scoring systems. |
|------------------------------------|-----------------|---------------|
| Duration of mechanical ventilation | 0.100           | 0.501         |
| Number of organ dysfunction        | 0.245           | 0.086         |
| GCS                                | -0.387          | 0.005         |
| APACHE score                       | 0.243           | 0.089         |
| SOFA score                         | 0.283           | 0.046         |

Significant p value < 0.05
addition, Wang et al. [15] reported a significant positive correlation between ΔPCO₂ and the SOFA score (r = 0.318, p < 0.001). The GCS was lower in the high ΔPCO₂ group than the normal group but not reached a significant level (p = 0.062). This alteration could be explained by cerebral hypoperfusion.

In the present study, serum lactate was significantly higher (p = 0.012) in high ΔPCO₂ group (3.6 ± 1.5) than the normal group (1.8 ± 0.7). Furthermore, van Beest et al. [10] reported that ΔPCO₂ was inversely correlated with lactate clearance and reduction in SOFA score after 24 hours, which was explained by the observed significant lower cardiac index in the high gap group.

The serum potassium level showed a significant negative correlation (p value=0.01) with ΔPCO₂ value. The low potassium level associated with high ΔPCO₂ could be explained by the presence of stress associated with sepsis, shock, or infarction that enhances catecholamines release. The catecholamines in turn activates the Na-K-ATPase enzyme that drowed potassium intra-cellular [17,18].

As regard organ dysfunction in ICU, high ΔPCO₂ group showed higher number of organ dysfunction than normal ΔPCO₂ group but not reached a significant level (p value = 0.625). Robin et al [13] detected similar results. They reported high percentage of patients with high ΔPCO₂ among patients with organ dysfunction.

In the high ΔPCO₂ group, there was a significant increase (p = 0.042) in the ICU 28- day mortality rate (69% versus 28.6%) than the normal group. Similar results were reported by Mallat et al. [19] with 75% mortality within 28-days for the high ΔPCO₂ group versus 42% for the normal group (p = 0.003). Van beest et al. [10] reported a higher mortality rate in the high ΔPCO₂ group than the normal group (29% versus 21%) but without a significant statistical difference.

In addition, Mesquida et al. [20] demonstrated an increased mortality rate among patients with high ΔPCO₂/Ca-vO₂ ratios. However, Ospina-Tascon et al. [16] found that lactate and ΔPCO₂/Ca-vO₂ were independently associated with mortality at multivariate analysis, among a series of hemodynamic variables in septic shock. Similar results were reported by Gavelli et al. [21]

**Conclusions:** ΔPCO₂ can be used as a reliable index for early prediction of organ dysfunction and clinical outcome in patients with sepsis and septic shock in ICU.

**Recommendations:** we recommend further studied on larger patient sample. We also advise to select specific group of patients with uniform data to avoid bias in the outcome.
