Ca2+-dependent modulation via calmodulin, with consensus CaM-binding IQ motif playing a key role, has been documented for most high-voltage-activated Ca2+ channels. The skeletal muscle Ca,v1.1 also exhibits Ca2+-/CaM-dependent modulation. Here, whole-cell Ca2+ current, Ca2+ transient, and maximal, immobilization-resistant charge movement (Qmax) recordings were obtained from cultured mouse myotubes, to test a role of IQ motif in function of Ca,v1.1. The effect of introducing mutation (IQ to AA) of IQ motif into Ca,v1.1 was examined. In dysgenic myotubes expressing YFP-Ca,v1.1AA, neither Ca2+ currents nor evoked Ca2+ transients were detectable. The loss of Ca2+ current and excitation-contraction coupling did not appear to be a consequence of defective trafficking to the sarcolemma. The Qmax in dysgenic myotubes expressing YFP-Ca,v1.1AA was similar to that of normal myotubes.

These findings suggest that the IQ motif of the Ca,v1.1 may be an unrecognized site of structural and functional coupling between DHPR and RyR.

1. Introduction

Calcium entering the cell through voltage-gated Ca2+ channels plays an important role in mediating a wide variety of cellular events and includes feedback processes that regulate activity of the channel itself. The Ca2+-dependent modulation of channel activity mediated by the Ca2+-binding protein calmodulin (CaM) is found in many ion channels including the Ca,v1 family [1]. Ca2+-dependent inactivation (CDI) of Ca,v1.2 is mediated by CaM, and its structural determinants have been assigned to the proximal region of the C-terminus of Ca,v1.2 [1, 2]. Three domains have been identified within this region: a Ca2+- binding EF-hand motif, a CaM-tethering site, and a CaM-binding IQ motif. The EF-hand motif, located ~16 residues beyond the end of the last transmembrane segment (IVS6), is absolutely necessary for CDI. The CaM-tethering site, which consists of both preIQ3 and IQ motifs, resides 50 amino acids downstream from the EF-hand motif and binds Ca2+-free CaM (apo-CaM) at resting [Ca2+]i. The IQ motif resides downstream from the EF-hand motif and the pre-IQ3 domain, and it binds Ca2+-CaM. When the interaction of CaM with either of these domains is compromised, CDI is reduced or eliminated [1, 2].

Recently, it has been demonstrated that the skeletal muscle L-type Ca2+ channel (Ca,v1.1) also displays CDI mediated by CaM and that CaM associates with Ca,v1.1 in vivo [3]. The initial 200 amino acids of the C-terminus of the Ca,v1.1 are highly conserved and contain the above-described domains including the IQ motif. CaM binding to the IQ motif of Ca,v1.2 channel has been shown to be necessary for CDI, and the mutation of the isoleucine (I1624) and glutamine (Q1625) to alanines (AA) in the IQ motif of Ca,v1.2 resulted in ablation of CDI and significant reduction of apoCaM binding to Ca,v1.2 [1, 2, 4]. Whether the IQ motif in Ca,v1.1 plays a similar role remains to be determined.

In the present work, myotubes cultured from normal and dysgenic (lacking endogenous Ca,v1.1) mice were used to investigate the role of the IQ motif in the function of Ca,v1.1. The results presented demonstrate that the IQ motif in the Ca,v1.1 is critical for function of Ca,v1.1 as a voltage sensor as well as Ca2+ channel. Furthermore, the results indicate that the IQ motif may be a previously unrecognized site of protein-protein interaction between Ca,v1.1 and the skeletal muscle ryanodine receptor (RyR1) and may play a role in skeletal muscle excitation-contraction (EC) coupling.
2. Experimental Procedures

2.1. Molecular Biology. The coding sequence of yellow fluorescent protein (YFP)-tagged Ca\textsubscript{1.1} channel (YFP-Ca\textsubscript{1.1}) was a gift from Dr. K. Beam and is described in detail elsewhere [5]. The residues isoleucine (I) and glutamine (Q) at codons 1529-1530 of rabbit Ca\textsubscript{1.1} [6] were substituted with alanine (A) using the QuikChange II mutagenesis kit (Stratagene, La Jolla, CA), using the YFP-Ca\textsubscript{1.1} as a template. The construct YFP-Ca\textsubscript{1.1AA} was verified by restriction digest analysis and sequencing.

2.2. Cell Cultures. Primary myotubes were cultured from normal or dysgenic newborn mouse skeletal muscle as previously described [3]. For confocal microscopy purposes, primary cultures of myotubes were plated onto 35 mm culture dishes with integral no. 0 glass coverslip bottoms (MatTek) instead of Primaria dishes. Approximately one week after plating, dysgenic myotubes were injected with expression plasmids (cDNAs) encoding either YFP-Ca\textsubscript{1.1} or YFP-Ca\textsubscript{1.1AA} at concentrations of 0.2 μg/μL, respectively. In experiments assessing the effects of CaM on Ca\textsuperscript{2+} transients, normal myotubes (~one week in culture) were injected with expression plasmids encoding CaM\textsubscript{wt} or CaM\textsubscript{1234} (gift of Dr. Yue) and green fluorescent protein (pEGFP-C1, BD Biosciences Clontech, CA) at concentrations of 0.1 and 0.02 μg/μL, respectively. Successfully transfected myotubes were identified 36–48 hours after injection by their yellow or green fluorescence under UV illumination.

2.3. Electrophysiology. Patch pipettes were constructed of borosilicate glass and had resistances of 1.8–2.5 MΩ when filled with the standard internal solution, which contained (in mM) 145 Cs-aspartate, 10 Cs\textsubscript{2}-EGTA, 5 MgCl\textsubscript{2}, and 10 HEPES (pH 7.4 with CsOH). The external solution contained (in mM) 145 tetraethylammonium chloride (TEA-Cl), 10 CaCl\textsubscript{2}, 0.003 tetrodotoxin, and 10 HEPES (pH 7.4 with TEA-OH). The holding potential was −80 mV, and currents were elicited by hyperpolarizing voltage steps (30 mV amplitude) from −50 mV. Ca\textsuperscript{2+} currents were normalized by linear fitting of the current during depolarization to +40 mV. The maximum amount of charge that can be moved (Q\textsubscript{max}) was obtained by integrating the charge movement current at test potential of +40 mV. Linear leak and capacity currents were subtracted on line using −P/4 delivered from the holding potential (−80 mV) before each pulse. Charge movements were normalized to total cell capacitance (nC/μF).

To measure relative changes in voltage-gated Ca\textsuperscript{2+} release from the SR, the Ca\textsuperscript{2+} indicator K\textsubscript{3}Fluo-3 (0.5 mM) (Molecular Probes) was included in the pipette solution. After rupture of the cell membrane and entry into the whole cell configuration, cells were allowed to dialyze for about 5 min before recording in order to achieve adequate loading with indicator dye. Fluorescent emission was measured by a photomultiplier system (Biomedical Instrumentation Group, University of Pennsylvania). The set of filters used to record the fluorescent signal from Fluo-3 was as follows: excitation band-pass filter of 470/20 nm; dichroic long-pass mirror (510 nm); emission long-pass filter of 520 nm. After rupture and dye loading into the cell, the baseline fluorescence (F\textsubscript{base}) was monitored. The increase in fluorescent signal during depolarization was expressed as ΔF/F, where ΔF represents the increase in fluorescence above baseline fluorescence (ΔF = F\textsubscript{transient} − F\textsubscript{base}), and F is F\textsubscript{base}. Peak fluorescence during each test pulse was plotted as a function of test potential V and fitted according to the following equation:

\[
\Delta F = \frac{\Delta F/F_{\text{max}}}{1 \ + \ \exp\left(\frac{V_{1/2} - V}{k_F}\right)},
\]

where (ΔF/F)\textsubscript{max} is the maximal fluorescent change, V\textsubscript{1/2} is the potential for half-maximal activation of the Ca\textsuperscript{2+} transient, and k\textsubscript{F} is a slope factor.

All recordings were performed at room temperature (~20°C), and data are reported as mean ± SEM; n indicates the number of myotubes tested. Data sets were statistically compared by an unpaired, two-sample Student’s t-test, with a confidence interval of at least 95%.

2.4. Confocal Microscopy. Cells were bathed in rodent ringer (in mM: 146 NaCl, 5 KCl, 2 CaCl\textsubscript{2}, 1 MgCl\textsubscript{2}, 11 glucose, 10 HEPES; pH 7.4 adjusted with NaOH) and examined with an LSM 510 META laser scanning microscope (Zeiss, Thornwood, New York) with 40X oil immersion objective. The laser line (514 nm) of the argon laser (30 mW maximum output, operated at 50% or 6.3 A) was used to excite YFP remaining at the end of test pulse by the peak current, and this ratio was used to quantify the level of inactivation

\[
r_{\text{800}} = \frac{I_{\text{end}}}{I_{\text{peak}}}.
\]
fluorophore. Emissions of YFP were recorded in single-track configuration with a long-pass filter of 530 nm (Chroma, Rockingham, Vermont). Fluorescence signals were analyzed by the 510 LSM Image Examiner software (Zeiss, Thornwood, New York).

2.5. Immunocytochemistry. Primary cell cultures were plated onto 35 mm culture dishes with integral no. 0 glass coverslip bottoms (MatTek). Myotubes expressing constructs of Cav1.1 were identified by fluorescence. The cultures will be fixed with 100% methanol at −20 °C for a minimum of 20 min. Cells were then incubated for 1 hour in PBS (phosphate-buffered saline) containing 1% BSA (bovine serum albumin) and 10% goat serum to block unspecific labeling. After 3 washes with PBS/BSA (.2%), cell cultures were incubated with specific primary antibody against the RyR1 (34C, Developmental Studies Hybridoma Bank (DSHB), UI) (dilution 1 : 4000) overnight at 4°C. Cells were washed out 3 times with PBS/BSA (.2%), followed by 1 hour of incubation with secondary antibody conjugated with Alexa 568 (at final dilution 1 : 5,000, goat anti-rabbit IgG, Invitrogen). Cells were then washed 3 times with PBS/BSA (.2%) to remove unbind secondary antibody and assessed with a confocal microscope.

3. Results

Ca
2+
-binding ability of CaM does not affect skeletal muscle EC coupling. First, I addressed the question whether the Ca
2+-binding ability of CaM plays any role in skeletal muscle EC coupling. Overexpressed mutant CaM which does not bind Ca
2+ (CaM
1234) can displace approximately 70% of endogenous CaM, as reflected by abolishment of CDI of Cav1.1 [3]. However, overexpression of either CaM
wt or CaM
1234 in normal myotubes did not significantly affect either current-voltage (I/V) relationship (Figure 1(a)) or voltage-gated Ca
2+ release from SR as indicated by similar peak fluorescence-voltage relationship (ΔF/F-V) in comparison with uninjected normal myotubes (Figure 1(b)). This result suggests that either the Ca
2+-binding ability of CaM or CaM itself does not play a role in skeletal muscle EC coupling. However, CaM associates with Cav1.1 in vivo [3] and that indicates the possibility that CaM may still serve as a structural subunit of Cav1.1, that is, that interaction between CaM and Cav1.1 can stabilize the DHPR complex. By doing so, it may also ensure proper structural and functional coupling between DHPR and RyR1.

Therefore, I examined whether CaM association with Cav1.1 is necessary for its function as a voltage sensor for EC coupling. The IQ motif of Cav1.1 has been shown to bind CaM similar to IQ motifs of Cav1.3 and Cav2 channels [7]. Introduction of the mutation IQ/AA in the IQ motif of the cardiac L-type Ca
2+ channel (Cav1.2) resulted in abolishment of CDI and significant reduction of apoCaM binding to Ca1.2 [2, 4]. Thus, corresponding IQ motif mutation in the C-terminus of Cav1.1 was obvious place to start.

The mutation (IQ/AA) in the CaM-binding site of Cav1.1 disables function of Cav1.1 as a Ca
2+ channel and voltage sensor for EC coupling. I introduced the IQ/AA mutation in the C-terminus of Cav1.1 and investigated how this...
mutation will alter Ca_{1.1} function as Ca^{2+} channel and voltage sensor for EC coupling. Introduction of the mutation IQ/AA in the IQ motif of Ca_{1.2} resulted in abolishment of CDI and significant reduction of apoCaM binding to Ca_{1.2} [2, 4]. Whether IQ motif in the Ca_{1.1} plays a similar role is unknown. Dysgenic myotubes expressing either YFP-Ca_{1.1} or YFP-Ca_{1.1AA} were used to examine the role of IQ motif in Ca^{2+}-dependent inactivation (CDI) of Ca_{1.1}. Injections of plasmids encoding various constructs of Ca_{1.1} into dysgenic myotubes at concentrations of 0.2–0.5 μg/μL have been previously demonstrated to produce a similar extent of maximal, immobilization-resistant charge movement and similar Ca^{2+} current densities as normal myotubes, which corresponds to similar protein expression levels [3, 6, 8–10].

Figure 2(a) shows Ca^{2+} currents mediated by YFP-Ca_{1.1} expressed in dysgenic myotube. The fraction of current remaining at the end of the pulse (r_{800}) displayed a U-shaped voltage dependence (data not shown), consistent with a current-dependent inactivation process. In such a process, the extent of inactivation varies in proportion with the amplitude of the inward calcium current, which in turn depends on the number of conducting channels and the electrochemical driving force on calcium. Inactivation was minimal at a test potential of +10 mV, as reflected by an r_{800} value of 0.9 ± 0.08 (n = 7), and maximal at a test potential of +40 mV, as reflected by a minimum r_{800} value of 0.74 ± 0.03 (n = 7). Correspondingly, the Ca^{2+} current attained its maximum conductance at +40 mV (Figure 1(c)). Thus, Ca^{2+} currents mediated by YFP-Ca_{1.1}
displayed a current-dependent inactivation process, current-voltage (I-V) relationship (Figure 2(c)), and maximal Ca\textsuperscript{2+} ion conductance (\(G_{\text{max}} = 166 \pm 18 \text{ nS/nF}; n = 7\)) similar to the endogenous Ca\textsubscript{v}1.1 of normal myotubes [3]. These results suggest that YFP fused to the N-terminus of Ca\textsubscript{v}1.1 does not interfere with channel function.

In contrast, dysgenic myotubes expressing YFP-Ca\textsubscript{v}1.1\textsubscript{AA} (Figures 2(b) and 2(c)) displayed either very small (<1pA/pF) or no measurable Ca\textsuperscript{2+} currents. This is a very dramatic and surprising result considering that the corresponding mutation (IQ/AA) in the IQ motif of Ca\textsubscript{v}1.2 resulted only in ablation of CDI but did not affect the I-V relationship of Ca\textsuperscript{2+} currents mediated by Ca\textsubscript{v}1.2 [2]. Further voltage-gated Ca\textsuperscript{2+} currents and SR Ca\textsuperscript{2+} release were measured simultaneously from dysgenic myotubes expressing YFP-Ca\textsubscript{v}1.1\textsubscript{AA} and compared with recordings from uninjected normal myotubes and normal myotubes overexpressing CaM\textsubscript{wt} or CaM\textsubscript{1234}. The voltage-gated Ca\textsuperscript{2+} release from SR was completely abolished in dysgenic myotubes expressing YFP-Ca\textsubscript{v}1.1\textsubscript{AA} (Figure 2(d)).

The loss of Ca\textsubscript{v}1.1\textsubscript{AA} function could be a result of several scenarios such as that mutation caused misfolding of protein and insufficient membrane targeting or that protein-protein interaction between RyR1 and Ca\textsubscript{v}1.1 was significantly disturbed. If the latter possibility is the case, this result suggests that either the IQ motif itself or association of CaM with Ca\textsubscript{v}1.1 is necessary for orthograde signaling from Ca\textsubscript{v}1.1 to RyR1, which underlies skeletal muscle EC coupling.

The IQ/AA mutation does not prevent proper targeting of Ca\textsubscript{v}1.1 into sarcolemma. The severe loss of function, abolished Ca\textsuperscript{2+} current and orthograde signaling mediated by the Ca\textsubscript{v}1.1\textsubscript{AA}, could be explained by compromised targeting of Ca\textsubscript{v}1.1 to the T-SR junction as a result of incomplete protein folding.

Figure 3 shows confocal images of yellow fluorescence from a dysgenic myotube expressing either YFP-Ca\textsubscript{v}1.1 or YFP-Ca\textsubscript{v}1.1\textsubscript{AA}. Expression of YFP-Ca\textsubscript{v}1.1 (a) or YFP-Ca\textsubscript{v}1.1\textsubscript{AA} (b) resulted in the appearance of small yellow fluorescence puncta located near the cell surface. The small puncta correspond to groups of Ca\textsubscript{v}1.1 localized to T-SR junctions; these puncta are similar in size and distribution to those of Ca\textsubscript{v}1.1 foci revealed by immunohistochemistry [11]. There is a similar staining of the membrane and distribution of puncta in both myotubes, suggesting that both constructs are likely targeted to T-SR junctions.

To confirm targeting of YFP-Ca\textsubscript{v}1.1\textsubscript{AA} to the sarcolemma, the Q\textsubscript{max} was measured at +40 mV (Figure 4). The Q\textsubscript{max} in dysgenic myotubes expressing Ca\textsubscript{v}1.1\textsubscript{AA} (5.9 \pm 0.5 nC/\mu F; \(n = 27\)) was similar to that of normal myotubes (5.5 \pm 0.4 nC/\mu F; \(n = 16\)), but significantly larger (\(P < 0.001\)) than in dysgenic myotubes alone (2.5 \pm 0.2 nC/\mu F; \(n = 18\)). This finding suggests that IQ/AA mutation in Ca\textsubscript{v}1.1 did not prevent the protein from being properly targeted or undergoing voltage-dependent conformational changes, which strongly suggest proper folding as intramembrane segment S4 of Ca\textsubscript{v}1.1 is responsible for voltage-dependent movement.

To further confirm Ca\textsubscript{v}1.1\textsubscript{AA} proper targeting into T-SR junctions and site of EC coupling, I investigated colocalization of Ca\textsubscript{v}1.1 and RyR1. Dysgenic myotubes expressing either YFP-Ca\textsubscript{v}1.1 or YFP-Ca\textsubscript{v}1.1\textsubscript{AA} (yellow fluorescence: YFP was artificially assigned as green) were incubated with specific primary antibody against the RyR1 followed by incubation with secondary antibody conjugated with Alexa 568 (red fluorescence). Colocalization of green and red fluorescence results in yellow pattern suggests colocalization of YFP-Ca\textsubscript{v}1.1 and RyR1 in T-SR junctions in vivo (see Figures 5(g) and 5(h)). Colocalization patterns of YFP-Ca\textsubscript{v}1.1\textsubscript{AA} with RyR1 were compared to YFP-Ca\textsubscript{v}1.1 and RyR1 patterns in 5 different experiments. Colocalization patterns of either YFP-Ca\textsubscript{v}1.1 or YFP-Ca\textsubscript{v}1.1\textsubscript{AA} with RyR1 were similar and have been analyzed by MetaMorph 7 software (Molecular Devices). Colocalization in near surface slices of z-stacks of YFP-Ca\textsubscript{v}1.1 and RyR1 was 83 \pm 4\% (\(n = 7\)), and colocalization of YFP-Ca\textsubscript{v}1.1\textsubscript{AA} and RyR1 was 85 \pm 2\% (\(n = 7\)). These results strongly suggest that YFP-Ca\textsubscript{v}1.1\textsubscript{AA} is targeted into T-SR junctions.

Together these results suggest that the IQ/AA mutation is not likely to affect protein folding within membrane. Furthermore, much more drastic alternation or deletions

FIGURE 3: YFP-Ca\textsubscript{v}1.1\textsubscript{AA} displays similar expression pattern as YFP-Ca\textsubscript{v}1.1 in dysgenic myotubes. Confocal images of either YFP-Ca\textsubscript{v}1.1 (a) or YFP-Ca\textsubscript{v}1.1\textsubscript{AA} (b) yellow fluorescence in dysgenic myotubes. Bar 50 \mu m.
terminus of Ca v1.1 is critical for function of Ca v1.1 as a voltage sensor as well as a Ca2+ channel. The average maximal, immobilization-resistant charge movement at +40 mV (Qmax) obtained from the indicated number of myotubes for each group. The charge movements were elicited by 25 ms depolarizations from a pedestal potential (−50 mV) to +40 mV. Symbols and error bars represent mean ± SEM.

in Ca v1.1 sequence did not have such dramatic effects [12, 13].

Taking altogether, the loss of both ionic Ca2+ current and skeletal muscle EC coupling in Ca v1.1AA along with charge movement similar to normal myotubes suggests that the IQ motif of the Ca v1.1 may be unrecognized site of protein-protein interaction between Ca v1.1 and RyR1 and play a role in both orthograde and retrograde signaling.

4. Discussion

The present study provides new information about the skeletal muscle L-type Ca2+ channel (Ca v1.1). Specifically, the data demonstrate in vivo that the IQ motif in the C-terminus of Ca v1.1 is critical for function of Ca v1.1 as a voltage sensor as well as a Ca2+ channel. Furthermore, the results indicate that the IQ motif, in addition to II-III loop, may be a previously unrecognized site of protein-protein interaction between Ca v1.1 and RyR1 and, thus, may play a role in skeletal muscle EC coupling.

Ca v1.1 is localized in regions of the T-tubular membrane that are closely apposed to the sarcoplasmic reticulum (i.e., the T-SR junction), and the primary role of Ca v1.1 is to serve as the voltage sensor for skeletal muscle EC coupling. The second protein that plays a major role in this process is the skeletal muscle ryanodine receptor (RyR1). RyR1 is localized in junctional SR membrane and functions as calcium release channel. The mechanism of signal transmission between Ca v1.1 and RyR1 is still incompletely understood, but the most accepted view is that they are mechanically coupled and interact with each other through protein-protein interaction (orthograde and retrograde signaling). Orthograde signaling is the signal from Ca v1.1 to RyR1, in which movement of the voltage sensors in Ca v1.1 trigger opening of RyR1 and release of Ca2+ from the SR (EC coupling). Retrograde signaling is communication from RyR1 to Ca v1.1, in which RyR1 somehow increases the amount of L-type Ca2+ current mediated by Ca v1.1 [8, 9].

The Ca2+ conductance of Ca v1.1 channel is not necessary for functional excitation-contraction coupling between RyR1 and Ca v1.1; however, a direct protein-protein interaction between these two proteins in multiple sites is. It has been shown that cytoplasmic loops of Ca v1.1 and several regions of RyR1 play important role for normal physiological EC coupling in skeletal muscle [10, 14–17]. It has been also shown that protein-protein interaction between RyR1 and Ca v1.1 is necessary for Ca v1.1 display of Ca2+ conductance (retrograde signaling) [8]. It is clear that there are multiple contact sites between RyR1 and Ca v1.1 and not all of them are recognized and understood, yet. The most investigated region of contact between RyR1 and Ca v1.1 in Ca v1.1 is II-III cytoplasmic loop, but other regions play a role [14, 15].

In the present experiments, normal myotubes and dysgenic myotubes expressing either YFP-Ca v1.1 or YFP-Ca v1.1AA were used to examine the role of the IQ motif in both functions of Ca v1.1, as a voltage sensor in EC coupling and Ca2+ channel. The primary cultures of skeletal muscle myotubes provide a natural cellular environment for Ca v1.1. First, I examined whether a fusion of YFP to Ca v1.1 would interfere with its function. The Ca2+ currents mediated by YFP-Ca v1.1 displayed an I-V relationship similar to the endogenous Ca v1.1 [3], suggesting that YFP fused on the N-terminus of Ca v1.1 does not interfere with its channel function, as was also shown by others [5]. Endogenous Ca v1.1 also exhibits CaM-mediated Ca2+-dependent inactivation (CDI) [3]. The Ca2+ currents mediated by YFP-Ca v1.1 also displayed current-dependent inactivation similar to the CDI of endogenous Ca v1.1, further supporting observation that fusion of YFP with Ca v1.1 does not interfere with channel function.

Second, I examined how IQ/AA mutation in Ca v1.1 will affect its function. Surprisingly, the intriguing finding of the present study was that dysgenic myotubes expressing YFP-Ca v1.1AA displayed either very small or no measurable Ca2+ currents.

Figure 4: Ca v1.1AA generates normal densities of intramembrane charge movement. The average maximal, immobilization-resistant charge movement at +40 mV (Qmax) obtained from the indicated number of myotubes for each group. The charge movements were elicited by 25 ms depolarizations from a pedestal potential (−50 mV) to +40 mV. Symbols and error bars represent mean ± SEM.
Figure 5: Ca\textsubscript{1.1AA} is targeted to T-SR junctions. Confocal images of colocalization of either YFP-Ca\textsubscript{1.1} (a) or YFP-Ca\textsubscript{1.1AA} (b) green fluorescence and immunolabeled RyR1 ((d) and (e)) red fluorescence in dysgenic myotubes. (g) and (h) represent overlay of (a) and (d), and (b) and (e), respectively. The control dysgenic myotube (no Ca\textsubscript{1.1}) immunolabeled without (c) and with (f) primary Ab(34C). Bar, 20 μm.

to the \(Q_{\text{max}}\) measured in dysgenic myotubes expressing various constructs of wt Ca\textsubscript{1.1} at the similar experimental conditions elsewhere [6, 7].

The amount of \(Q_{\text{max}}\) in dysgenic myotubes expressing YFP-Ca\textsubscript{1.1AA} suggests that IQ/AA mutation in Ca\textsubscript{1.1} did not prevent the protein from being properly targeted and that protein can undergo voltage-dependent conformational changes. The size of small measurable Ca\textsuperscript{2+} currents measured in some (6 out of 14) of the dysgenic myotubes expressing Ca\textsubscript{1.1AA} (<1pA/pF) was similar to L-type Ca\textsuperscript{2+} currents measured in dyspedic (lacking a functional gene of RyR1) myotubes [7], suggesting a loss of retrograde signaling from RyR1. Endogenous Ca\textsubscript{1.1} channels are present in sarcolemma of the dyspedic myotubes in similar density as in normal myotubes, as was demonstrated by comparable \(Q_{\text{max}}\) (dyspedic: 4.0 ± 1.4 nC/μF; normal: 6.4 ± 2.8 nC/μF) [7]. Thus, the amount of \(Q_{\text{max}}\) measured in dysgenic myotubes expressing Ca\textsubscript{1.1AA} (5.9 ± 0.5 nC/μF) is in
good agreement with the previously published values, and indicates that the IQ/AA mutation may have also disrupted retrograde signaling between Ca_{1.1} and RyR1. The similar expression patterns and comparable colocalization of YFP-Ca_{1.1} and YFP-Ca_{1.1AA} with RyR1 in dysgenic myotubes obtained by confocal microscopy and immunocytochemistry further support the argument that YFP-Ca_{1.1AA} seems to be folded and targeted properly to the T-SR junctions. In addition, much more drastic alternation or deletions in Ca_{1.1} sequence did not have such dramatic effects [12, 13].

Third, the IQ/AA mutation in C-terminus of Ca_{1.1} had a dramatic effect on its function as a voltage sensor for EC coupling. Even though amount of Q_{max} in dysgenic myotubes expressing YFP-Ca_{1.1AA} is sufficient to support EC coupling (see above), the voltage-gated Ca^{2+} release from SR was completely abolished in these cells. This finding suggests that either tethering of CaM to Ca_{1.1} as a structural subunit or the IQ motif itself is necessary for orthograde signaling between Ca_{1.1} and RyR1 (EC coupling). Overexpression of CaM_{wt} and CaM_{1234} in normal myotubes did not significantly affect the peak fluorescence-voltage relationship (Δ°F/ΔV) in comparison with un.injected normal myotubes, suggesting that the Ca^{2+}-binding ability of CaM does not play a role in skeletal muscle EC coupling in single twitch contractions.

For the first time, the present study shows that the IQ motif plays a role in both orthograde (skeletal muscle EC coupling) and retrograde (Ca^{2+} current) signaling between Ca_{1.1} and RyR1 in vivo. Several regions of RyR1 were shown to participate in protein-protein interactions between Ca_{1.1} and RyR1. However, until recently only the II-III loop of the Ca_{1.1} has been thought to be necessary to convey orthograde and retrograde signaling between Ca_{1.1} and RyR1. The present findings suggest that the C-terminus in addition to the II-III loop participates in and is necessary for the correct transmission of signals between Ca_{1.1} and RyR1. These results support previously published in vivo findings that in addition to the II-III loop of Ca_{1.1} additional intracellular loops of Ca_{1.1} are necessary to restore the full extent of orthograde and retrograde signaling between Ca_{1.1} and RyR1 [15]. The present findings also support in vitro results from pull-down assays, where it was demonstrated that CaM-binding region of RyR1 (3614–3543) interacts with the proximal C-terminus of Ca_{1.1} (1393–1527) in the absence of CaM [18, 19]. It was also shown that CaM binding to the RyR1 is not essential for skeletal EC coupling [20]. This would indicate together with binding studies [18] that CaM association to either Ca_{1.1} or RyR1 is not crucial for skeletal muscle EC coupling, but CaM-binding domains of both Ca_{1.1} and RyR1 are. For example, it has been shown that CaM-binding region of RyR1 binds to IQ peptide of Ca_{1.2} and in pull-down assay binds to Ca_{1.1} [18]. It still remains to be determined whether CaM itself needs to be tethered to Ca_{1.1} to ensure signaling and more experiments are in progress.

In conclusion, the results from confocal microscopy, immunocytochemistry, charge movement, and Ca^{2+} transients obtained from dysgenic myotubes expressing YFP-Ca_{1.1AA} indicate that the IQ motif in the C-terminus of Ca_{1.1} plays a crucial role in both orthograde (EC coupling) and retrograde (Ca^{2+} current) signaling between Ca_{1.1} and RyR1.

Acknowledgments

The authors thanks Dr. David Yue for kindly providing CaM_{wt} and CaM_{1234} constructs Dr. Kurt Beam for discussions, providing YFP-Ca_{1.1} construct, and for his support of preliminary studies and Dr. Brett Adams for his helpful insights and constructive criticism of the paper. This work was supported by MDA Research Grant and PIRG06-GA-2009-256580, Marie Curie Actions FP7-PEOPLE-2009-RG, EU.
