Abstract

In this study we investigated the prevalence of the oppA gene, encoding the oligopeptide binding protein (OppA) of the major bacterial oligopeptide uptake system (Opp), in different species of the genus Xanthomonas. The oppA gene was detected in two Xanthomonas axonopodis strains among eight tested Xanthomonas species. The generation of an isogenic oppA-knockout derivative of the Xac 306 strain, showed that the OppA protein neither plays a relevant role in oligopeptide uptake nor contributes to the infectivity and multiplication of the bacterial strain in leaves of sweet orange (Citrus sinensis) and Rangpur lime (Citrus limonia). Taken together these results suggest that the oppA gene has a recent evolutionary history in the genus and does not contribute in the physiology or pathogenesis of X. axonopodis.

Key words: Xanthomonas, Xac, OppA, oligopeptide uptake system, ABC transporter.

Received: September 16, 2009; Accepted: December 9, 2009.

Introduction

Oligopeptides play important roles in bacterial nutrition, representing important sources of nitrogen, carbon and other elements. They are also involved in intercellular gene signaling processes, such as those involved in chemotaxis, conjugation, spore formation and the development of the competence state (Detmers et al., 2001). Three distinct oligopeptide uptake systems, specifically committed to the transport of dipeptides (Dpp), tripeptides (Tpp) and oligopeptides (Opp), have been characterized in Escherichia coli, Salmonella enterica pv Typhimurum and Sinorhizobium meliloti (Hiles et al., 1987; Nogales et al., 2009).

In gram-negative bacteria, the Opp system belonging to the ATP-binding cassette (ABC) transporter family, comprises various functional and structural domains, viz., the substrate binding protein in the periplasm (OppA), two transmembrane pore-forming proteins (OppB and OppC), and the two membrane-associated ATPases (OppD and OppF) which generate energy from ATP hydrolysis required for the transport process. The opp genes are frequently organized as a polycistronic operon (oppABCD/F), in which the binding component (OppA) is usually expressed at a higher stoichiometric ratio compared to the other components (Higgins and Hardie, 1983; Hiles et al., 1987; Monnet, 2003). Besides a role in nutrition, the Opp system participates in various physiological processes, such as the recycling of cell-wall peptides, quorum sensing and adhesion to host cells, genetic competence and sporulation (Rudner et al., 1991; Cundell et al., 1995; Alloing et al., 1998; Claverys et al., 2000; Detmers et al., 2001). Opp-encoding genes are found in approximately 50% of those bacterial species with available genomic sequences, although as yet, in only a few cases have their specific roles, either in physiology or pathogenesis, been investigated.

The genus Xanthomonas is comprised of a ubiquitous group of bacterial pathogens which infect crops of major economical interest, such as orange, grape, rice, soy bean and bean, among others (Chan and Goodwin, 1999). Genome sequencing projects of Xanthomonas species have highlighted the multiplicity of ABC transporters, particularly those responsible for nutrient uptake (Silva et al.,
2002; Qian et al., 2005; Lee et al., 2005; Thieme et al., 2005; Salzberg et al., 2008; Vorhölter et al., 2008). So far, opp genes have been detected in the X. axonopodis pv. citri 306 (Vauterin et al., 1995) (Xac) strain, but not in three X. campestris pv. campestris (Xcc) strains (Silva et al., 2002; Qian et al., 2005; Vorhölter et al., 2008), neither in the genomes of X. oryzae pv. oryzae (Xoo) (Lee et al., 2005; Salzberg et al., 2008) and X. campestris pv. vesicatoria (Xcv) (Thieme et al., 2005). These observations indicate that the Opp system may have a specific physiological role in Xac strains and may affect features like pathogenicity and host selectivity.

In the present study, we investigated the distribution of the oppA gene among different Xanthomonas species. In addition we evaluated the putative physiological role of OppA, namely that of the oligopeptide-binding component, in the Xac 306 strain, based on the generation of a specific knockout mutant. The present evidence demonstrated that the oppA gene is restricted to two X. axonopodis strains and does not play a specific role in the virulence of this phytopathogen.

Material and Methods

Bacterial strains and growth conditions

All the bacterial strains used in this work are listed in Table 1. Bacterial strains were routinely cultivated in Circle Grow (CG) (Bio 101) broth at 30 °C. For the oligopeptide uptake assays, the strains were cultivated overnight in M9 minimal medium supplemented with proline, methionine, histidine, tryptophan (100 μg mL⁻¹ each), or in the same medium with proline replaced by the YPLG peptide (0.5 μg mL⁻¹).

Construction of a Xac oppA-knockout strain

The generation of an oppA-knockout Xac 306 derivative strain, denominated XoppA2, has already been described (Oshiro et al., 2006).

Gene screening and expression studies

Genomic DNA from all the Xanthomonas isolates was isolated, according to the procedure described by Llop et al. (1999). The oppA gene was amplified with genomic DNA, as template and the oligonucleotides Fw 5’- CGGC GCTCGGGTACCGTGGCGTTGGCGGTGCTG-3’ and Rv 5’- GGCGGATCTA GATCAGTGGTGGTGGTGTTTGCTCACCCAGGCGTC- 3’, based on the reported opp operon sequence (Silva et al., 2002). For Southern-blot analysis, genomic DNA from the tested samples was digested with Pst I, and then transferred to a nylon membrane (Hybond-N, Amersham Biosciences). A probe for the oppA gene was synthesized with [α-³²P]-dCTP, by random primer labeling, using the PCR generated DNA fragment described above. The labeled probe was hybridized with the membrane at 42 °C for 16-20 h before exposure to autoradiography films (Kodak T-MAT G/RA film). Western-blot analyses were carried out with whole cell proteins sorted in 12.5% (w/v) acrylamide gels, followed by transference to nitrocellulose membranes (Millipore) and development of bands reacting with polyclonal monocpecific anti-OppA antibody, as previously described (Moutran et al., 2004). The anti-OppA serum was raised in mice

parenterally immunized with a His-tagged protein produced in *E. coli* transformed with a recombinant pET-28a vector carrying the Xac *oppA* gene without the native signal peptide (Moutran et al., 2004).

**Oligopeptide uptake assay**

*Xac* 306 and *XoppA2* cells, grown overnight, were harvested by centrifugation, washed twice with saline and inoculated (1:100) in the M9 medium without proline and with the tetrapeptide YPLG (Sigma) (0.5 µg mL⁻¹). After various incubation periods at 28 °C, aliquots of the culture supernatant were harvested and dried by vacuum centrifugation. The peptides were extracted with cold methanol and submitted to RP-HPLC separation (LC 10A-VP binary Shimadzu HPLC system). Each fraction was analyzed in an ESI mass spectrometer (LCQDuo, ThermoFinnigan, USA), equipped with a nanospray source and connected to a nanoHPLC system (UltiMate HPLC System, LC Packings, Dionex, USA). The samples were introduced into the spectrometer by a flow rate at 1 µL/min, and then diluted in a solution of 5% acetonitrile and 0.2% formic acid. The spray voltage was kept at 1.8 kV, capillary voltage at 46 V, capillary temperature at 180 °C and tube lens offset at -5 V. MS spectra were collected in centroid mode in the 50 to 2000 m/z range.

**Protease assays**

Cell-free culture medium aliquots of *Xac* 306 and *XoppA2* strains prepared in M9 medium, were incubated with YPLG (0.5 µg mL⁻¹) for different periods at 20-28 °C. The presence of the tetrapeptide was monitored by RP-HPLC spectrometry, as described above. The same experiments were repeated in the presence of EDTA (ethylenediaminetetraacetic acid) added to the medium aliquots at a final concentration of 1 mM.

**Plant infection experiments**

Cells of the *Xac* 306 and *XoppA2* strains were diluted in sterile distilled water to a final absorbance (OD₆₀₀) of 0.3. Aliquots (100 µL) of cell suspensions were inoculated into the leaves of two sensitive citrus hosts, namely sweet orange (*Citrus sinensis*) and Rangpur lime (*Citrus limonia*), through injuries in the leaf surface. Infiltrations were carried out at the lower part of the leaf using a needleless syringe, as previously reported by Laia et al. (2009).

**Studies of in vivo growth kinetics**

*In vivo* growth tests of *Xac* strains were carried out with sweet orange (*C. sinensis*). The whole procedure followed the experimental conditions described by Laia et al. (2009). Five discs of at least 6 different leaves were assayed for each time point and for each tested bacterial strain.

**Results**

*Opp* genes have only been discovered in the genome of the *Xac* 306 strain (Silva et al., 2002). Moreover, no orthologs have been detected in genomes of the *Xcc* ATCC33913, 8004 and B100 strains (Silva et al., 2002; Qian et al., 2005; Vorhölter et al., 2008), the *Xcv* 85-10 strain (Thieme et al., 2005), nor the *Xoo* strains KACC10331 (Lee et al., 2005), PX099⁴ (Salzberg et al., 2008) and MAF311018 (GenBank accession number AP008229). These results indicate that *opp* genes are restricted to *Xac* and may have a specific physiological role, such as host specificity, in this bacterial species. To further investigate the distribution of the *Opp* system in *Xanthomonas* species, the *oppA* gene was screened in eight additional *Xanthomonas* species without known genome sequences, including one additional *Xcv* strain, six isolates of different *Xanthomonas* species (*X. bromi*, *X. codiaeai*, *X. sacchari*, *X. pisi*, *X. theicola*, and *X. melonis*, and two *X. axonopodis pv aurantiifolii* (*Xaa*) strains (409 and 381). As shown in Figure 1, the *oppA* gene was detected only in the *Xac* 306 and *Xaa* 381 strains, previously classified within the citrus pathovar, but currently, and according to the low DNA homology with *Xac* strains, considered as belonging to a different pathovar altogether (Schaad et al., 2005). The *oppA* gene detected in both strains were actively transcribed and translated during *in vitro* growth. This was demonstrated by Western-blot analysis carried out with a specific anti-OpP*A* polyclonal antibody generated in mice immunized with purified recombinant Opp*A* protein from the *Xac* 306 strain. As shown in Figure 1C, the anti-OpP*A* serum recognized a reactive protein band in the periplasm fraction of the two *X. axonopodis* strains (*Xac* 306 and *Xaa* 381), but not in extracts of any other *Xanthomonas* species.

or strain. The expression of OppA protein was apparently constitutive, since no significant difference in its expression was detected in whole-cell extracts of cells kept under different culture medium conditions, supplemented or not with oligopeptides or leaf extracts of susceptible citrus hosts (data not shown).

The restricted distribution of the oppA gene in the *Xanthomonas* genus suggests that the Opp system plays a specific physiological role in these two strains, but not in the other tested species and strains. In order to investigate the putative role of OppA in the uptake of oligopeptides by *X. axonopodis* strains, we generated an isogenic oppA defective knockout mutant strain (*XoppA2*) by a gene replacement approach in which the native gene was replaced by non-functional knockout alleles.

The uptake of a synthetic tetrapeptide (YPLG) was monitored by mass spectrometry, using both the parental *Xac* 306 strain and the OppA-deficient *XoppA2* strain based on the removal of the synthetic peptide from the culture medium during bacterial cell growth. The choice of the substrate peptide was based mainly on molecular modeling studies and docking analyses of different peptides to the *Xac* OppA structural model (Moutran et al., 2007). In order to validate the experimental approach, we employed two *E. coli* strains: one (the SS320 strain) proficient in the opp operon, and the other (the SS5013 strain) being an isogenic derivative deleted in the entire opp operon (Andrews and Short, 1985). As indicated in Figures 2A and 2B, the oligopeptides were efficiently removed from the culture supernatant by the *E. coli* SS320 strain, but not by the *opp*-defi-

**Figure 2** - Oligopeptide uptake by *E. coli* K12 and *Xac* 306 strains. The profiles show the relative abundance versus mass spectrum (m/z = 448.4) corresponding to YLPG. (A) Profile detected in culture supernatant of *E. coli* SS320 strain in which no signal can be detected at m/z = 448.4 (range 2 x 10^3). (B) Peptide profile detected in culture supernatants of *E. coli* SS5013 (opp defective) strain, in which the presence of the tetrapeptide is clearly visible, as indicated by the arrow (range 2 x 10^3). (C) Culture supernatant of the *Xac* 306 strain, in which no matching ion corresponding to YLPG could be detected (range 5 x 10^3). (D) Culture supernatant of the *XoppA2* strain, in which no matching ion corresponding to YLPG could be detected (range 8 x 10^3). The arrow points to the ion corresponding to the YLPG peptide.
cient SS5013 strain. On the other hand, when the same experiment was repeated with Xac 306 and its isogenic oppA derivative, XoppA2, no tetrapeptide was detected in the culture supernatants of either strain, after incubation periods ranging from 12 to 24 h at 28 °C (Figure 2C,D). This might be explained, either by the presence of an alternative Opp-independent oligopeptide uptake system in the Xac 306 strain, or by the production and secretion of proteases in the culture media.

In order to discover the reason for the rapid removal of tetrapeptide from Xac cultures, the oligopeptide was incubated with aliquots from the culture supernatant of both Xac strains. No tetrapeptide was detected after incubation with culture supernatants of both parent and mutant strains (Figure 3B/D). In addition, EDTA prevented the in vitro peptide degradation following incubation with culture supernatants of both Xac strains (Figure 3A,C). Such result indicated that the apparent uptake of the tetrapeptide was mainly attributed to the proteolytic attack by secreted proteases produced by the Xac 306 strain. Attempts to block protease activity in culture supernatants of actively growing Xac strains with EDTA failed, probably due to the large amount of secreted proteases (data not shown).

In order to evaluate the putative role of OppA in Xac pathogenesis in citrus hosts, we infected two susceptible citrus hosts, viz., sweet orange (C. sinensis) and Rangpur lime (C. limonia), with the Xac 306 and XoppA2 strains, and compared the induction of leaf lesions and multiplication in leaf tissues. Up to 10 days following infection, no difference was detected in the symptoms inflicted by the

**Figure 3** - Proteolytic degradation of the tetrapeptide in culture supernatants of Xac 306 and XoppA2 strains. The profiles show relative abundance versus time, with the YLPG peptide eluting after 3 min. Profiles detected in culture supernatant of the Xac 306 strain (A) with EDTA (range of 2.6 x 10^4) or (B) without EDTA (range of 1.2 x 10^5). Profiles detected in culture supernatant of the XoppA2 strain (C) with EDTA (range of 7.6 x 10^3) or (D) without EDTA (range of 1.5 x 10^5). In both samples treated with EDTA, the absorbance peak corresponding to the YLPG peptide is clearly present. The dotted line indicates the 3 min elution time.
two *Xac* strains in either citrus host (Figure 4). Furthermore, no significant difference in the growth curves of either of the two strains was detected during their multiplication in sweet orange leaf tissues (Figure 4). These results clearly indicated that deletion of the oppA gene did not impair the growth of *Xac* in susceptible citrus hosts.

**Discussion**

In the present study we investigated the prevalence of the oppA gene, and the corresponding OppA protein, in different *Xanthomonas* species, an important group of phytopathogens inflicting heavy losses in several economically relevant crops. The present results demonstrated that, in contrast to other bacterial groups, such as enterobacterial species and lactic acid bacteria, the oppA gene was detected in only two out of the three tested *X. axonopodis* strains. Furthermore, studies screening revealed that oppA is also absent in the genomes of the *Xcc* 8004 and *Xcv* 85-10 strains, as well as two *Xoo* strains with reported genome sequences (Lee et al., 2005; Thieme et al., 2005). We also demonstrated that early-branching *Xanthomonas* species, including the ancestral *X. sacchari* and *X. theicola*, do not carry the oppA gene. Similarly, as recently defined by Parkinson and colleagues (2007), other three established *Xanthomonas* phylogenetic groups, represented by *X. bromi*, *X. melonis*, *X. pisi* and *X. codiaeii*, also do not carry the oppA gene. In spite of our previous observations that the opp operon does not present biased codon usage, distinct GC content or the presence of adjacent insertion sequences and transposable-encoding genes (Moutran et al., 2004), the present results indicate that the opp genes have been acquired in a recent evolutionary event in the *Xanthomonas* genus and remained restricted to some *X. axonopodis* strains.

Generation of an oppA-deficient strain led us to conclude that the Opp system does not play a significant role in the uptake of a tetrapeptide, the most likely substrate of OppA encoded by the *Xac* 306 strain, as previously determined by molecular modeling tools (Moutran et al., 2007). Monitoring of the peptide uptake by mass spectrometry showed that, in contrast to *E. coli*, the tetrapeptide is quickly degraded by secreted proteases produced by both *Xac* 306 and XoppA2 strains. Hence, it may be deduced that the abundant production of extracellular proteases produced by *Xac*, as well as other *Xanthomonas* species, could constitute an abundant source of amino acids derived from the proteolytic degradation of host proteins. Under such conditions, the function of an oligopeptide uptake system would be dispensable, since free amino acid residues are actively transported by different dedicated uptake systems. This conclusion is supported by the lack of the oppA gene in most *Xanthomonas* species and the presence of a stop codon located 129 bp downstream of the first structural codon in the *Xac* 306 oppA/F cistron, this encoding the ATPase component required for the generation of energy to the transport process (Silva et al., 2002; Moutran et al., 2004). The finding that eight other *Xanthomonas* species, besides one *Xaa* strain, which do not carry opp genes, lends further support to the notion that, in contrast to other bacterial species, *Xanthomonas* oppA genes really represent pseudo genes on the way to disappearing from the genomes of these strains.

In accordance with this idea, no measurable difference in colonization, infection and generation of leaf lesions was observed in two susceptible citrus hosts infected with either the *Xac* 306 or the isogenic oppA-deficient strains. The absence of any significant pathogenic impact involving the *Xac* 306 strain in various citric hosts, lends further support to the conception that the Opp system is not functional in this strain and does not contribute to the pathogenesis of this bacterial strain in different citrus hosts. Collectively, the present evidence indicates that the *Xac* OppA, and consequently the Opp system, in contrast to other bacterial species, does not play a relevant physiological role.

**Acknowledgments**

The present study was supported by a grant from the Fundação de Amparo à Pesquisa do Estado de São Paulo (FAPESP). The authors would like to thank the helpful
technical assistance of Loren C. Silva, Cristiano B. Ferreira, and Marcelo Laia. We wish to especially thank Dr. Y.B. Rosato for supplying us with most of the tested Xanthomonas strains.
