Abstract: In the dual-mode model predictive control (MPC) framework, the size of the stabilizable set, which is also the region of attraction, depends on the terminal constraint set. This paper aims to formulate a larger terminal set for enlarging the region of attraction in a nonlinear MPC. Given several control laws and their corresponding terminal invariant sets, a convex combination of the given sets is used to construct a time-varying terminal set. The resulting region of attraction is the union of the regions of attraction from each invariant set. Simulation results show that the proposed MPC has a larger stabilizable initial set than the one obtained when a fixed terminal set is used.

Keywords: interpolation method; MPC; nonlinear

1. Introduction

Model predictive control (MPC) is an optimal controller that minimizes a cost index over a finite horizon implemented in the receding horizon framework. The advantage of MPC over conventional controllers is the ability to handle the state and control constraints. When the state is measured at a sampling time, an optimization problem is solved. However, only the first element of the optimal solution is applied to the system. Then, the whole procedure is repeated at the next sampling time [1].

The concept of a dual-mode MPC is widely used to guarantee the stability of MPC for both linear systems, e.g., [2,3], and nonlinear systems, e.g., [4-6]. The terminal penalty function is used as an upper bound of the infinite horizon cost needed to drive the state trajectory to the origin when the initial condition is in the terminal region. Moreover, closed-loop stability is ensured by forcing the terminal state to belong to a feasible and invariant set. Hence, the region of attraction is the set of initial conditions that can be steered to the terminal region in \( N \) steps or less, where \( N \) is the prediction horizon. In other words, it is a \( N \)-steps stabilizable set. Several studies have been devoted to formulate a terminal set that makes the region of attraction as large as possible. By increasing the prediction horizon, the domain of attraction can be enlarged at the expense of more computational effort due to the increasing number of decision variables [7]. Hence, in the literature, various approaches have been proposed to enlarge the region of attraction through a larger terminal set. In [8], it is shown that the saturated local control law is used to yield a considerably larger terminal constraint set. A sequence of sets is used in [9] to replace a single terminal set. The contractive set does not need to be invariant as long as there is an admissible control that eventually steers the states to an invariant set. Hence, a larger domain of attraction can be obtained by extending the sequence with a reachable set. In [10], the terminal constraint is only applied to the unstable states, giving the flexibility to have a larger set. A linear time-varying MPC is mostly used to extend a linear MPC with an enlarged terminal set for a nonlinear system, e.g., in [11-14].

Interpolation-based MPC for a linear system is studied by [15,16] to achieve a compromise between the size of domain attraction and the optimality. The MPC is designed by selecting
several invariant sets and expressing the terminal state as a convex combination of states belonging to the invariant sets. By doing that, the resulting terminal set becomes the convex hull of the predefined-invariant sets. For reducing the number of decision variables, the interpolation method can be implicitly employed, meaning that the terminal state is not explicitly expressed as the convex combination of several states but is still the convex hull of several invariant sets, e.g., in [17,18]. The design procedure starts by designing several stabilizing feedback control gains $K_i$, $i = 1, \ldots, m$, for a given linear time-invariant system. Then, feasible and invariant ellipsoids $E_i = \{x| x^T R_i^{-1} x \leq 1\}$, $R_i > 0$, are defined such that some necessary linear matrix inequalities (LMIs) are satisfied for each matrix $R_i$, $i \in [1,m]$. These LMIs are popularly used to show that $E_i$ can be applied as the terminal set for a linear MPC [19]. It is then shown that applying a convex combination to the $m$ given LMIs yields a new LMI. As a result, the set $E_\lambda = \{x| x^T (\sum_{i=1}^m \lambda_i R_i)^{-1} x \leq 1\}$ is a feasible and invariant set for any $\lambda_i \geq 0$ satisfying $\sum_{i=1}^m \lambda_i = 1$. In view of this, the method used in [17,18] is highly dependent on the definition of the invariant sets through the use of an LMI form. Although an LMI form has been widely applied for many applications, e.g., in a consensus problem [20,21], the terminal set for a nonlinear MPC is not generally defined in an LMI form; thus, the convex hull may not be an invariant set despite that the ingredient sets $E_i$ are invariant. To deal with this, a linear differential inclusion (LDI) is used in [12,13] to represent the nonlinear system. Specifically, the nonlinear system $\dot{x} = f(x,u)$ can be represented as $\dot{x} = \sum_{i=1}^m \zeta_i A_i x + \sum_{i=1}^m \zeta_i B_i u$ where $\sum_{i=1}^m \zeta_i = 1$ and $\sum_{i=1}^m \zeta_i = 1$ with properly chosen $(A_i, B_i)$. As a result, after computing all ellipsoids using a common LDI, the convex hull of the several invariant sets can be used as the terminal set of a nonlinear MPC [12]. However, LDI representation is generally conservative and is hard to obtain [22]. With this in mind, this paper is interested in applying a more general convex combination to several terminal sets of a nonlinear MPC.

This paper aims to enlarge the domain of attraction of a nonlinear MPC by having a larger terminal region. Given several feasible and invariant sets $E_i = \{x| x^T P_i x \leq \alpha_i\}$, $i = 1,2,\ldots,m$, this paper proposes a convex combination strategy to define a new set $E_\lambda$ to define a larger terminal set. The proposed strategy is different from the one discussed above as it does not require the help of LDI to make $E_\lambda$ to be used as a terminal set for a nonlinear MPC. Moreover, it is shown that $E_\lambda$ results in the union of $E_1,\ldots,E_m$. The feasibility and stability of the MPC can be guaranteed with the enlarged terminal set through the use of a common local Lyapunov function defined in all sets $E_i$. Numerical simulations demonstrate that the proposed MPC has a larger region of attraction than the one obtained by the conventional MPC.

**Notation**

Given any sets $E_1$ and $E_2 \subseteq \mathbb{R}^n$, the union and the convex hull of these sets are denoted by $E_1 \cup E_2$ and $\text{co}\{E_1, E_2\}$, respectively. For a square matrix $A \in \mathbb{R}^{n \times n}$, $A > 0$ denotes a positive definite matrix, and $\lambda_{\text{min}}(A)$ is the eigenvalue of $A$ whose absolute value is smallest and $\lambda_{\text{max}}(A)$ is defined similarly.

**2. Preliminary Result: Nonlinear MPC**

Consider discrete-time nonlinear systems:

$$x_{k+1} = f(x_k, u_k), \quad (1)$$

where $f : \mathbb{R}^n \times \mathbb{R}^{nu} \to \mathbb{R}^n$, $x_k$ is the state and $u_k$ is the input at time instant $k$. The system is subject to the control input and state constraints

$$u_k \in \mathbb{U}, \quad x_k \in \mathbb{X}, \quad \forall k \geq 0, \quad (2)$$

where $\mathbb{U} \subseteq \mathbb{R}^{nu}$ and $\mathbb{X} \subseteq \mathbb{R}^n$ are convex and compact sets. It is assumed that the state $x_k$ is measurable and there is neither external disturbance nor model uncertainty. The following assumption is required for system (1).
Assumption 1. The function $f$ is twice differentiable, and $f(0,0) = 0$.

Having this assumption, $(0,0) \in \mathbb{R}^{n \times m}$ is an equilibrium of system (1). The optimization problem for the finite horizon nonlinear MPC for nonlinear system (1) is formulated as follows:

$$
\min_{\ell_k} \sum_{i=0}^{N-1} \ell(x_{i|k}, u_{i|k}) + V(x_{N|k}) \tag{3}
$$

subject to

$$
x_{i+1|k} = f(x_{i|k}, u_{i|k}), i \in \{0, \ldots, N-1\}
$$

$$
u_{i|k} \in \mathcal{U}, x_{i|k} \in \mathcal{X}, i \in \{0, \ldots, N-1\}
$$

$$
x_0 = x_k, x_{N|k} \in \mathcal{E}
$$

where $\ell(x,u) = x^TQx + u^TRu$ and $x_k$ is the current state measurement. Here, $u_{i|k}$ and $x_{i|k}$ denote input and state predictions at time $k+i$ that are computed at time $k$. Thus, $\mathcal{U} = [u_{0|k}, u_{1|k}, \ldots, u_{N-1|k}]$ is the control prediction over the prediction horizon. The function $V: \mathbb{R}^n \to \mathbb{R}$ is known as the terminal penalty cost. The matrix $Q \geq 0$ and $R > 0$ are the weighting matrices for the state and input variables. Set $\mathcal{E}$ denotes the terminal penalty set where a popular choice for the terminal set is an ellipsoid set $\mathcal{E} := \{x \in \mathbb{R}^n | x^TPx \leq a \}$, where $P > 0$ is a symmetric matrix.

The nonlinear MPC design procedure starts by solving the optimization problem when the state $x_k$ is measured at the $k$th sampling time. As a result, the optimal control sequence $\mathcal{U}_k$ is obtained, and $u_k = u_{0|k}$ is applied to the plant. Therefore, the (implicit) model predictive control law is $\kappa_{MPC}(x_k) = u_{0|k}$. Afterward, the same procedure is repeated at the next sampling time. For details, see [1,5,23].

**Stability of MPC**

The terminal region $\mathcal{E}$ and terminal penalty function $V(x_{N|k})$ play a pivotal role in ensuring the stability of the nonlinear MPC (3). The following lemma describes the required condition for stability.

**Lemma 1.** [1,3] With $Q \geq 0$, $R > 0$, suppose that the following holds

- **A.1** $\exists \kappa(x)$ such that $\kappa(x) \in \mathcal{U}, \forall x \in \mathcal{E}$ (feasibility)
- **A.2** $f(x, \kappa(x)) \in \mathcal{E}, \forall x \in \mathcal{E}$ (invariance)
- **A.3** $\mathcal{E} \subseteq \mathcal{X}$
- **A.4** $V(f(x, \kappa(x))) - V(x) \leq -\ell(x, \kappa(x)), \forall x \in \mathcal{E}$

Then, the origin is asymptotically stable for the closed loop system $x_{k+1} = f(x_k, \kappa_{MPC}(x_k))$ with a region of attraction $\mathcal{F}^N$, i.e., $\mathcal{F}^N$ is the set of states steerable to $\mathcal{E}$ by an admissible control in $N$ steps or less.

For the purpose of enlarging the domain of attraction $\mathcal{F}^N$, this paper is interested in formulating an MPC in which its terminal set is defined as the convex combination of several invariant sets $\mathcal{E}_1, \mathcal{E}_2, \ldots, \mathcal{E}_m$ and is discussed in the next section.

### 3. MPC Based on the In-Between Terminal Set

In this paper, several sets are used as the ingredients of the time-varying terminal set for a nonlinear MPC. Specifically, given $m$ ellipsoids $\mathcal{E}_i = \{x \in \mathbb{R}^n | x^TP_1x \leq a_i \}, P_1 > 0, i = 1, \ldots, m$, let $\mathcal{E}_\lambda$ be an ellipsoid given by

$$
\mathcal{E}_\lambda = \{x \in \mathbb{R}^n | x^TP_\lambda x \leq a_\lambda \}, \tag{4}
$$
where

\[ P_\lambda := \sum_{i=1}^{m} \lambda_i p_i, \quad a_\lambda = \sum_{i=1}^{m} \lambda_i a_i, \quad \sum_{i=1}^{m} \lambda_i = 1, \]  

(5)

and \( \lambda_i > 0, i = 1, \ldots, m \). From (5), a convex combination of \( P_i \) and \( a_i, i = 1, \ldots, m \), are used to define the new ellipsoid \( E_\lambda \). In [24], \( E_\lambda \) is called as the in-between ellipsoid. Note that \( E_\lambda = E_i \) when \( \lambda_i = 1, i \in \{1, \ldots, m\} \). Hence, \( E_i \subset \bigcup_{\lambda \in \Sigma} E_\lambda \) holds true, where \( \Sigma := \{ (\lambda_1, \ldots, \lambda_m) \mid \sum_{i=1}^{m} \lambda_i = 1, \lambda_i \geq 0, i = 1, \ldots, m \} \). In view of this, \( E_i \) in (4) can be seen as a general way to define all \( E_i, i = 1, \ldots, m \).

A question arises on how the set \( \bigcup_{\lambda \in \Sigma} E_\lambda \) looks like. Note that \( \bigcup_{\lambda \in \Sigma} E_\lambda \) includes all the possible set \( E_\lambda \) for any \( \lambda_i \in [0, 1] \) such that \( \sum_{i=1}^{m} \lambda_i = 1 \). In the following lemma, it is shown that \( E_\lambda \) is a subset of the union of \( E_i \).

**Lemma 2.** \( E_\lambda \) in (4) is an ellipsoid satisfying

\[ E_\lambda \subset E_1 \cup E_2 \cup \ldots \cup E_m, \]  

(6)

for any \( \lambda_i \geq 0 \) satisfying \( \sum_{i=1}^{m} \lambda_i = 1 \).

See Appendix A for the proof.

Since \( E_\lambda = E_i \) when \( \lambda_i = 1, \lambda_j = 0, j \neq i, i, j \in [1, m] \), and (6) holds true, it follows that \( \bigcup_{\lambda \in \Sigma} E_\lambda = E_1 \cup \ldots \cup E_m \), meaning that the union of all possible \( E_\lambda \) results in the union of \( E_1, \ldots, E_m \). Figure 1 demonstrates Lemma 2 when only two ellipsoids \( E_1 \) and \( E_2 \) are considered. The property of \( E_\lambda \) given by (6) is depicted in Figure 1b with \( \lambda_2 = 1 - \lambda_1 \). It is important to note that convex combination (5) does not result in convex hull of \( E_1, \ldots, E_m \) as a convex hull is made by applying a convex combination of ellipsoids expressed by \( \{x \mid x^T R_i^{-1} x \leq 1\} \) with \( R_i > 0 \). See Table 1. Instead, as can be seen in Figure 1, the convex combination (5) yields the union of \( E_1, \ldots, E_m \). Since, in general, \( \{E_1 \cup \ldots \cup E_m\} \subset \text{co}\{E_1\} \) holds true, (6) implies that \( E_\lambda \subset E_\lambda \subset \text{co}\{E_1\} \). Although this shows that the convex combination used in this paper results in a smaller set than the one obtained in [17,18], it is shown that under the following assumption, the in-between ellipsoid \( E_\lambda \) can be used as the terminal set of an MPC and requires a relatively simple procedure even for nonlinear systems.

**Table 1.** Convex combinations (5) is different from the one used in [17,18]. Note that \( R_i = [P_i / a_i]^{-1} \).

| \( E_1 \) | \( E_\lambda \) |
|----------------|----------------|
| \{x \mid x^T R_i^{-1} x \leq 1\} | \{x \mid x^T (\sum_{i=1}^{m} \lambda_i R_i)^{-1} x \leq 1\} \subset \text{convex hull} |
| This paper \{x \mid x^T P \leq a_i\} | \{x \mid x^T (\sum_{i=1}^{m} \lambda_i P_i) x \leq \sum_{i=1}^{m} \lambda_i a_i\} \subset \text{union} |

**Figure 1.** (a) For given ellipsoids \( E_1 \) and \( E_2 \), \( E_\lambda = \{x \mid x^T P_\lambda x \leq a_\lambda, P_\lambda = \sum_{i=1}^{2} \lambda_i P_i, a_\lambda = \sum_{i=1}^{2} \lambda_i a_i\} \).
Assumption 2. For given \( Q \geq 0 \) and \( R > 0 \), suppose that there exist \( m \) pairs of \((E_i, \kappa_i(\cdot))\), \( i = 1, \ldots, m \), satisfying A.1-A.3 of Lemma 1, and \( P_L \in \mathbb{R}^{n \times n} \) such that

\[
f(x, \kappa_i(x))^T P_L f(x, \kappa_i(x)) - x^T P_L x \leq -\ell(x, \kappa_i(x)), \quad \forall x \in E_i, \quad i = 1, \ldots, m,
\]

where \( P_L \) is a symmetric and positive definite matrix and \( E_i = \{x|x^T P_i x \leq \alpha_i\}\).

In the literature, there are several methods to find an invariant set and a terminal penalty cost such that the stability of the quasi-infinite horizon-based MPC (3) can be guaranteed, e.g., [5,25,26]. In these studies, \( V(x) = x^T P x \) is shown as a local Lyapunov function in the set \( E = \{x|x^T P x \leq \alpha\} \) under a stabilizing control law \( \kappa(x) = Kx \), meaning that A1-A4 in Lemma 1 are satisfied. Thus, \( V(x) \) and \( E \) can be used as the terminal penalty and the terminal region of a nonlinear MPC, respectively. However, Assumption 2 requires the existence of a common local Lyapunov function \( V = x^T P_L x \) defined in all the sets \( E_1, \ldots, E_m \) [27]. Suppose that \( \kappa_i(x), P_i, \alpha_i \) satisfying Lemma 1 are given in the first place, the common Lyapunov function can be found by choosing a positive definite matrix \( P_L > P_i \) such that the following holds true

\[
\min_{x \in E_i} \left[ x^T P_L x - f(x, \kappa_i(x))^T P_L f(x, \kappa_i(x)) - \ell(x, \kappa_i(x)) \right] \geq 0, \quad \forall i \in [1, m].
\]

Note that (8) is equivalent with (7). A method based on the existing method [5,25,26] can also be employed to make Assumption 2 holds true. In fact, the following lemma can be obtained by extending the result in [26].

Lemma 3. Suppose that Assumption 1 holds true, and that the following linearized system of (1) in the neighborhood of the origin is controllable

\[
x_{k+1} = Ax_k + Bu_k.
\]

Let \( u_k = Kx_k \) be a stabilizing feedback control law with feedback gain \( K \) and \( P \) be a positive definite matrix satisfying

\[
\tau^2 A_K^T P A_K^T - P = -(Q + K^T R K),
\]

where \( A_K := A + BK, \tau \in \left( 1, \frac{1}{\lambda_{max}\{A_K\}} \right) \). Moreover, suppose that \( P_L \in \mathbb{R}^{n \times n} \) is a positive definite matrix such that

\[
\tau^2 A_K^T P_L A_K - P_L \leq \tau^2 A_K^T PA_K - P.
\]

Then, there exists a constant \( \alpha \) specifying an ellipsoid in the form of \( E = \{x|x^T P x \leq \alpha\} \) such that \( Kx_k \in U, \forall x \in E, x \in X, E \) is an invariant set for nonlinear system (1), and that the following holds true

\[
f(x, Kx)^T P_L f(x, Kx) - x^T P_L x \leq -\ell(x, Kx), \quad \forall x \in E.
\]
Given $\mathcal{E}_1, \ldots, \mathcal{E}_m$, the proposed MPC with enlarged terminal region is computed by solving the following optimization problem

$$
\min_{\mathcal{U}_k, \lambda_{1,k}, \ldots, \lambda_{m,k}} J_N(\mathcal{U}_k, x_k) \quad (13)
$$

subject to

$$
x_{i+1|k} = f(x_{i|k}, u_{i|k}), i \in \{0, \ldots, N-1\}
$$

$$
u_{i|k} \in \mathcal{U}, x_{i|k} \in \mathcal{X}, i \in \{0, \ldots, N-1\}
$$

$$
x_{0|k} = x_k, \; x_{N|k} \in \mathcal{E}_{\lambda,k}
$$

$$
\sum_{i=1}^m \lambda_{i,k} = 1, \; \lambda_{i,k} \geq 0, \; i \in \{1, \ldots, m\}
$$

where $\mathcal{E}_{\lambda,k} = \{ x \in \mathbb{R}^n | x^T [\sum_{i=1}^m \lambda_{i,k} P_i] x \leq \sum_{i=1}^m \lambda_{i,k} \kappa_i \}$,

$$
J_N(\mathcal{U}_k, x_k) = \sum_{i=0}^{N-1} \ell(x_{i|k}, u_{i|k}) + x_{N|k}^T P_L x_{N|k}.
$$

and $\mathcal{U}_k = \{ u_{0|k}, u_{1|k}, \ldots, u_{N-1|k} \}$. In the following, it is shown that the stability of the proposed MPC computed by (13) can be guaranteed.

**Theorem 4.** For the nonlinear system (1), suppose that Assumptions 1 and 2 hold true, and that the optimization problem (13) with $Q \geq 0$ and $R > 0$ is initially feasible. Then, the closed-loop system consisting of the system (1) and the nonlinear MPC obtained from (13) is asymptotically stable.

**Proof.** Let $\lambda^*_{1,k}, \ldots, \lambda^*_{m,k}$, and $u^*_{i|k}$, $i = 0, \ldots, N-1$, be the optimal solution of problem (13) at time $k$. Then, the optimal vector $\mathcal{U}^*_k$ and $\lambda^*_k$ are given by

$$
\mathcal{U}^*_k = \{ u^*_{0|k}, u^*_{1|k}, \ldots, u^*_{N-1|k} \},
$$

$$
\lambda^*_k = \{ x^*_{0|k}, x^*_{1|k}, \ldots, x^*_{N-1|k}, x^*_{N|k} \}.
$$

Having this, the optimal cost function at time $k$ is given by

$$
J^*_N(\mathcal{U}^*_k, x_k) = \sum_{i=0}^{N-1} \ell(x^*_{i|k}, u^*_{i|k}) + x^*_N P_L x^*_N. \quad (14)
$$

By Lemma 2, there is at least one $j, j \in \{1, \ldots, m\}$, such that $x^*_{N|k} \in \mathcal{E}_j$. Note that $\lambda_{j,k+1} = 1, \lambda_{i,k+1} = 0, i \in \{1, \ldots, m\}, i \neq j$, are feasible at $k+1$ since $\mathcal{E}_j$ is an invariant set with $\kappa_j(x)$. Thus, the following is a feasible control sequence at $k+1$

$$
\hat{\mathcal{U}}_{k+1} = \{ u^*_{1|k}, u^*_{2|k}, \ldots, u^*_{N-1|k}, \kappa_j(x^*_{N|k}) \}. \quad (15)
$$

The resulting state prediction is given by

$$
\hat{x}_{k+1} := \{ x^*_{1|k}, x^*_{2|k}, \ldots, x^*_{N-1|k}, x^*_{N|k}, f(x^*_N, \kappa_j(x^*_{N|k})) \}. \quad (16)
$$

where $f(x^*_N, \kappa_j(x^*_{N|k})) \in \mathcal{E}_j$ due to the invariant set $\mathcal{E}_j$. Using (15) and (16), the cost function at $k+1$ is

$$
J_N(\hat{\mathcal{U}}_{k+1}, x_{k+1}) = \sum_{i=1}^{N-1} \ell(x^*_{i|k}, u^*_{i|k}) + \ell(x^*_{N|k}, \kappa_j(x^*_{N|k})) + f(x^*_N, \kappa_j(x^*_{N|k}))^T P_L f(x^*_N, \kappa_j(x^*_{N|k})). \quad (17)
$$
Note that \( J_N(\tilde{U}_{k+1}, x_{k+1}) \) is not the optimal cost function at \( k + 1 \). Moreover, (17) can be rewritten as follows

\[
J_N(\tilde{U}_{k+1}, x_{k+1}) = J_N^*(U^*_k, x_k) - \ell(x^*_0, u^*_0) + \ell(x^*_N, x^*_N) + f(x^*_N, \kappa(x^*_N))U^T f(x^*_N, \kappa(x^*_N)) - x^*_N P_1 x^*_N
\]

where \( J_N^*(U^*_k, x_k) \) is defined in (14). Applying (7) to this inequality yields

\[
J_N(\tilde{U}_{k+1}, x_{k+1}) \leq J_N^*(U^*_k, x_k) - \ell(x^*_0, u^*_0).
\]

As a result, the optimal cost function at time \( k + 1 \), denoted by \( J_N^*(U^*_{k+1}, x_{k+1}) \), satisfies

\[
J_N^*(U^*_{k+1}, x_{k+1}) \leq J_N(\tilde{U}_{k+1}, x_{k+1}) \leq J_N^*(U^*_k, x_k).
\]

In other words, the optimal cost function is a Lyapunov function for system (1). Having this and the terminal state constraint, nonlinear system (1) under the solution of (13) is asymptotically stable at the origin. \( \square \)

Note that optimization problem (13) uses \( x^T P_k x \) as the fixed penalty cost function but employs a time-varying terminal set \( \mathcal{E}_{A,k} = \{ x \in \mathbb{R}^n | x^T \sum_{i=1}^{m} \lambda_{i,k} P_i x \leq \sum_{i=1}^{m} \chi_{i,k} \} \). Since \( \lambda_{i,k}, i = 1, \ldots, m \), can be any non-negative constants such that their sum is one, the union of \( \mathcal{E}_{1,k}, \ldots, \mathcal{E}_{m,k} \) can be seen as the terminal set of (13), meaning that the proposed method potentially yields larger region of attraction when the region of attraction of each invariant set \( \mathcal{E}_{i} \) is not the subset of the others, i.e., \( \mathcal{F}_{i}^N \not\subseteq \mathcal{F}_{j}^N, i, j \in \{1, \ldots, m\}, i \neq j \).

Although the resulting terminal set is not the convex hull of the predefined sets, the proposed method can be easily employed for a nonlinear system without the need for an LDI argument. Moreover, the ingredient sets \( \mathcal{E}_{i,k} \) can be obtained using a similar procedure as in [5,25], or [26]. In the next section, numerical simulations are used to investigate the performance of the proposed MPC for a nonlinear system.

4. Example

In this section, the optimization problem (13) is employed for two nonlinear systems. At first, numerical simulation on a control-affine system with \( x \in \mathbb{R}^2 \) is presented. Then, a three-dimensional system is used to investigate the proposed method for a general nonlinear system.

4.1. A Two-Dimensional Nonlinear System

Consider the following nonlinear system

\[
\begin{align*}
\dot{x}_1 &= -20x_1 + 10x_2 + 6u + 10x_1^2u, \\
\dot{x}_2 &= 20x_1 - 20x_2 + 6u - 40x_2^2u,
\end{align*}
\]

where \( x_1, x_2 \in \mathbb{R} \). The system is subjected to constraints \(-0.1 \leq u \leq 0.1, -2 \leq x_1 \leq 2, \) and \(-2 \leq x_2 \leq 2 \). The system is discretized and linearized with sampling time \( T = 0.05 \). For given \( Q = \text{diag}([0.5 \ 0.5]) \)
and $R = 0.5$, suppose that a state feedback controller is used as a stabilizing control law, i.e., $\kappa_i(x) = K_i x$.

Moreover, consider two pairs of $(E_i, \kappa_i(x))$, $i = 1, 2$, and $P_L$ satisfying Assumption 2 given by

$$K_1 = \begin{bmatrix} -0.0865 & 0.1364 \end{bmatrix}, \quad K_2 = \begin{bmatrix} -0.1246 & 0.1520 \end{bmatrix},$$

$$P_1 = \begin{bmatrix} 9.2062 & -5.7551 \\ -5.7551 & 5.4322 \end{bmatrix}, \quad P_2 = \begin{bmatrix} 3.8403 & 1.2193 \\ 1.2193 & 1.6077 \end{bmatrix},$$

$$P_L = \begin{bmatrix} 11.7274 & -3.9370 \\ -3.9370 & 7.9271 \end{bmatrix},$$

where $\alpha_1 = 0.95, \alpha_2 = 0.67$, and $P_L$ is computed using the procedure described in Appendix B. Figure 2 shows the sets $E_i, i = 1, 2$, and the estimate of region of attraction $F_{N_1}$ and $F_{N_2}$ for $N = 2$. In this example, the resulting region of attraction from $E_i$ is estimated by applying $E_i$ as a fixed terminal set for different initial conditions. The proposed MPC results in a time-varying terminal set at each sampling time $E_\lambda = \lambda_k E_1 + (1 - \lambda_k) E_2$ where $\lambda_k \in \mathbb{R}$ is depicted in Figure 3. Figure 4 demonstrates that, for any $x_0 \in F_{N_1} \cup F_{N_2}$, the states are steered to the origin. Moreover, the input constraint is satisfied as shown in Figure 5.

As shown in Figure 2 and Table 2, some initial conditions lead to infeasibility when only one set (i.e., either $E_1$ or $E_2$) is considered for the terminal region. Meanwhile, thanks to the time-varying terminal set $E_\lambda$, $F_{N_1} \cup F_{N_2}$ is the resulting region of attraction. As a result, the proposed MPC is feasible for all six different initial states in Table 2, meaning that a larger region of attraction is obtained. Let $\sum_{t=0}^{\infty} x_t^T Q x_t + u_t^T R u_t$ be the simulation cost. It is shown in Table 2 and Figure 6 that, compared to the cost obtained by the MPC with $E_i, i = 1, 2$ as the terminal region, the proposed MPC yields a comparable cost with a larger domain of attraction. In summary, the proposed nonlinear MPC with enlarged terminal set results in not only a larger region of attraction but also acceptable performance.

Table 2. Cost comparison between various terminal sets for given six different initial states.

| $x_0$ | $[-1; -1]$ | $[-0.1; -1.2]$ | $[1.5; -1.9]$ | $[1; 1.5]$ | $[0.1; 1.2]$ | $[-1.3; 1.8]$ |
|-------|------------|----------------|---------------|-------------|---------------|----------------|
| $E_1$ | 85.84      | 40.72          | Infeasible    | 126.38      | 40.72         | Infeasible     |
| $E_2$ | Infeasible | 32.70          | 49.43         | Infeasible  | 32.70         | 42.29          |
| $E_\lambda$ | 85.88      | 40.75          | 49.53         | 127.74      | 40.75         | 42.42          |

Figure 2. The invariant set $E_i$ and an estimate of the corresponding region of attraction $F_{N_i}$ with $N = 2$.

Since $E_\lambda \subset E_1 \cup E_2$, a larger region of attraction can be obtained, i.e., $F_{N_\lambda} = F_{N_1} \cup F_{N_2}$.
Figure 3. Variable $\lambda \in [0, 1]$ defining the time-varying terminal set $E_{\lambda}$.

Figure 4. State $x = [x_1; x_2]$ converges to the origin for all $x_0 \in F^N_1 \cup F^N_2$.

Figure 5. Control input $u$ satisfies input constraint.
4.2. A Three-Dimensional Nonlinear System

Consider the following nonlinear system [28,29]

\[
\begin{align*}
\dot{x}_1 &= -0.877x_1 + x_3 - 0.088x_1x_3 + 0.47x_1^2 - 0.019x_2^2 - x_2^2x_3 + 3.846x_1^3 - 0.215u_k + 0.28x_1^2u + 0.47x_1u^2 + 0.63u^3 \\
\dot{x}_2 &= x_3 \\
\dot{x}_3 &= -4.208x_1 - 0.396x_3 - 0.47x_1^2 - 3.564x_1^3 - 20.967u + 6.265x_1^2u_k + 46x_1u^2 + 61.1u^3.
\end{align*}
\]

(18)

Note that the considered system is not linear in the input variable \( u \). It is assumed that \( U = \{u | -3 \leq u \leq 3 \} \). Similar to the previous example, the weighting matrices \( Q \) and \( R \) are set to \( Q = \text{diag}(\{0.5 0.5 0.5\}) \) and \( R = 0.5 \). The following are two pairs of \( (\mathcal{E}_i, \kappa_i(x)) \), \( i = 1, 2 \), and \( P_L \) satisfying Assumption 2

\[
\begin{align*}
K_1 &= \begin{bmatrix} -0.40 & 1.57 & 0.28 \end{bmatrix}, & K_2 &= \begin{bmatrix} -1.24 & 1.95 & 0.26 \end{bmatrix}, \\
P_1 &= \begin{bmatrix} 19.3 & -70.5 & -4.6 \\ -70.5 & 426.9 & 29.9 \\ -4.6 & 29.9 & 6.1 \end{bmatrix}, & P_2 &= \begin{bmatrix} 136.1 & -205.4 & -11.1 \\ -205.4 & 341.4 & 20.7 \\ -11.1 & 20.7 & 3.7 \end{bmatrix}, \\
P_L &= \begin{bmatrix} 832.3 & -1221.2 & -68.7 \\ -1221.2 & 2056.1 & 122.8 \\ -68.7 & 122.8 & 22.8 \end{bmatrix}
\end{align*}
\]

and \( \kappa_i = 1, \ k = 1, 2 \). The resulting feasible and invariant sets \( \mathcal{E}_i, i = 1, 2 \), are shown in Figure 7. The set \( \mathcal{E}_1 \) is not a subset of \( \mathcal{E}_2 \), and vice versa. Figure 8 depicts several initial states when \( \mathcal{E}_i, i = 1, 2 \) is considered as the terminal set of a nonlinear MPC with \( N = 2 \). Note that there are several initial states which are only feasible when \( \mathcal{E}_1 \) is employed as the terminal set of a nonlinear MPC. Likewise, there are several initial states which are only feasible when \( \mathcal{E}_2 \) is considered. In view of this, similar as in the previous example, using both \( \mathcal{E}_1 \) and \( \mathcal{E}_2 \) as the ingredient to define the time-varying terminal set \( \mathcal{E}_k \) yields a larger region of attraction, i.e., \( \mathcal{E}_k = \lambda_k \mathcal{E}_1 + (1 - \lambda_k) \mathcal{E}_2 \). Applying the optimization problem (13) with \( N = 2 \) to few different initial conditions of (18) results in \( \lambda_k \) and the state trajectories \( x(t) \) depicted in Figure 9a,b, respectively. Note that the resulting terminal set can be larger than the one obtained here if we consider more ingredient sets \( \mathcal{E}_i \), i.e., \( m > 2 \).
Figure 7. The invariant set $E_1$ and $E_2$, $E_1, E_2 \in \mathbb{R}^3$, $i = 1, 2$, for system (18) where they are is plotted (a) in a three-dimensional space and (b) in view of $x_1$ and $x_2$ axes. Note that $E_1 \not\subset E_2$ and $E_2 \not\subset E_1$.

Figure 8. Few feasible initial states obtained using $E_i, i = 1, 2$ as the terminal set of a nonlinear MPC with $N = 2$, where they are is plotted (a) in a three-dimensional space and (b) in view of $x_1$ and $x_2$ axes. Note that some states are feasible only for the MPC with $E_i, i \in \{1, 2\}$.

Figure 9. (a) Resulting $\lambda \in [0, 1]$ defining the time-varying terminal set $E_\lambda \in \mathbb{R}^3$. (b) Trajectories from different initial states $x(0)$ which are feasible to either $E_1$ or $E_2$.

5. Conclusions

This paper proposes a new time-varying terminal set for the nonlinear MPC via a convex combination of given invariant and feasible sets. The resulting terminal set is the union of the
predefined sets. Compared to the existing results on enlarging the terminal set through a convex combination strategy, the proposed approach appears to be more general since it does not require linear differential inclusion (LDI) representation of the nonlinear system in order to implement the proposed nonlinear MPC scheme. The existence of a common local Lyapunov function in all the ingredient invariant sets plays a key role in guaranteeing the stability of the proposed MPC. The paper gives a general way to use several sets obtained from different state-feedback gains. Possible future research includes the extension of this work to a tracking MPC problem.

Author Contributions: I.R.F. surveyed the backgrounds of this research, designed the control strategies, and performed the simulations to show the benefits of the proposed method. J.-S.K. supervised and supported this study. All authors have read and agreed to the published version of the manuscript.

Funding: This study was supported by the Advanced Research Project funded by the SeoulTech (Seoul National University of Science and Technology).

Conflicts of Interest: The authors declare no conflict of interest.

Appendix A. Proof of Lemma 2

By definition, since $P_k$ is a symmetric and positive definite matrix, $E_\lambda$ is an ellipsoid. Next, for the purpose of proving (6), let us consider its contradiction, meaning that there exists $(\lambda_1, \ldots, \lambda_m)$ such that $E_\lambda$ is not in the union of $E_1, \ldots, E_m$. For such $(\lambda_1, \ldots, \lambda_m)$, there exists $\hat{x} \in \mathbb{R}^n$ satisfying the following conditions at the same time

\begin{align*}
\text{C.1} \quad & \hat{x}^T P_\lambda \hat{x} > a_i, \forall i = 1, \ldots, m, \\
\text{C.2} \quad & \hat{x}^T P_\lambda \hat{x} \leq a_\lambda.
\end{align*}

From C.1, $\hat{x}^T P_\lambda \hat{x} > \sum_{i=1}^m \lambda_i a_i = a_\lambda$ is obtained, which contradicts C.2. Thus, the claim is proven.

Appendix B. Common Lyapunov Function via Linearized System

Appendix B.1. Proof of Lemma 3

For all $\tau \in \left(1, \frac{1}{|\max(\Lambda_K)|}\right)$, all the eigenvalues of $\tau A_K$ lie in the unit circle since $A_K$ is Hurwitz. Thus, (10) admits a unique positive definite solution $P$. Since $(0, 0) \in U \times X$, there exist $\gamma > 0$ such that $E_0 = \{x | x^T P x \leq \gamma \}$ where $K \in U$, $\forall x \in E_0$, and $E_0 \subset X$. In light of this, the dynamics (1) in $E$ can be seen as an unconstrained nonlinear system, thereby, (1) with $u_k = K x_k$ can be written as

$$x_{k+1} = A_K x_k + \Phi x_k,$$

(A1)

where $\Phi(x_k) := f(x_k, K x_k) - A_K x_k$. Then, it remains to show that there exists $a \in [0, \gamma)$ such that (12), i.e., invariance holds true. Consider a candidate Lyapunov function $V(x) = x^T P L x$ for $P_L$ satisfying (11). It follows that

$$V(x_{k+1}) - V(x_k) = (A_K x_k + \Phi(x_k))^T P_L (A_K x_k + \Phi(x_k)) - x_k^T P_L x_k$$

$$= \tau^2 x_k^T A_K^T P_L A_K x_k - x_k^T P_L x_k + (\tau^2 - 1) x_k^T A_K^T P_L x_k - 2 x_k^T A_K^T P_L \Phi(x_k) + \Phi^T(x_k) P_L \Phi(x_k).$$

(A2)

In view of (11), there exists a positive semidefinite matrix $\Gamma \in \mathbb{R}^{n \times n}$ such that

$$\tau^2 A_K^T P_L A_K - P_L = \tau^2 A_K^T P A_K - P - \Gamma$$

(A3)

holds true, i.e., $\Gamma = P_L - \tau^2 A_K^T (P_L - P) A_K$. Using (A3) and the definition of $\Gamma$, (A2) can be written as

$$V(x_{k+1}) - V(x_k) = \tau^2 x_k^T A_K^T P A_K x_k - x_k^T P x_k - \psi(x_k),$$

(A4)
where
\[ \psi(x_k) = x_k^T \Gamma x_k + (\tau^2 - 1)x_k^T A_k^T P_k A_k x_k - 2x_k^T A_k^T P_k \Phi(x_k) - \Phi^T(x_k) P_k \Phi(x_k). \] (A5)

Note that \( V(x_{k+1}) - V(x_k) \leq \tau^2 x_k^T A_k^T P_k A_k x_k - x_k^T P_k x_k \) when \( \psi(x_k) \geq 0 \). Recall that, according to the Taylor’s Theorem, for a continuous and twice differentiable function \( g \) on an open interval \( I \) around \( a \), there is a value \( \eta \) between \( a \) and \( b \) so that
\[ g(b) = g(a) + g'(a)(b-a) + \frac{1}{2}g''(\eta)(b-a)^2. \] (A6)

In order to apply this to function \( \Phi \), let \( \eta_k \) be some value between \( a = 0 \) and \( b = x_k \). Then, function \( \Phi \) yields
\[ \Phi(x_k) = \frac{1}{2}x_k^T \partial^2 f(\eta_k, K \eta_k) x_k + \frac{1}{2}x_k^T \partial^2 f(\eta_k, K \eta_k) K x_k + \frac{1}{2}x_k^T K \partial^2 f(\eta_k, K \eta_k) x_k + \frac{1}{2}x_k^T K \partial^2 f(\eta_k, K \eta_k) K x_k, \]
owing to \( \Phi(a) = \Phi(0) = 0 \) and \( \Phi'(a) = \Phi'(0) = 0 \). Denote
\[ C(\Phi(x_k)) = \frac{\partial^2 f(\eta_k, K \eta_k)}{\partial^2 x_k} + \frac{\partial^2 f(\eta_k, K \eta_k)}{\partial x_k \partial x_k} K + K \partial^2 f(\eta_k, K \eta_k) K. \]
Let \( C_M \) be defined as follows
\[ C_M := \sup_{\eta_k \in E_0} \| C(\eta_k) \|. \]
Thus, \( \| \Phi(x_k) \| \leq \frac{1}{2}C_M \| x_k \|^2 \) for all \( x_k \in E_0 \). Furthermore,
\[ 2x_k^T A_k^T P_k \Phi(x_k) + \Phi^T(x_k) P_k \Phi(x_k) \leq C_M \| A_k \| \| P_k \| \| x_k \|^3 + \frac{C_M}{4} \| P_k \| \| x_k \|^4. \] (A7)

Let \( \alpha \in [0, \gamma) \) such that
\[ C_M \| A_k \| \| P_k \| \| x_k \|^3 + \frac{C_M}{4} \| P_k \| \| x_k \|^4 \leq (\tau^2 - 1) \lambda_{\min}(A_k^T P_k A_k) + \lambda_{\min}(\Gamma), \]
for all \( x_k \in E \). Then, \( C_M \| A_k \| \| P_k \| \| x_k \|^3 + \frac{C_M}{4} \| P_k \| \| x_k \|^4 \leq (\tau^2 - 1) \lambda_{\min}(A_k^T P_k A_k) \| x_k \|^2 + \lambda_{\min}(\Gamma) \| x_k \|^2 \). Note that \( \lambda_{\min}(A_k^T P_k A_k) \| x_k \|^2 \leq x_k^T A_k^T P_k A_k x_k \) and \( \lambda_{\min}(\Gamma) \| x_k \|^2 \leq x_k^T \Gamma x_k \). With this and (A7) in mind,
\[ 2x_k^T A_k^T P_k \Phi(x_k) + \Phi^T(x_k) P_k \Phi(x_k) \leq (\tau^2 - 1)x_k^T A_k^T P_k A_k x_k + x_k^T \Gamma x_k \forall x_k \in E. \]
It follows that \( \psi(x_k) \geq 0 \) for all \( x_k \in E \). Substituting this to (A4) and using (10) yield \( V(x_{k+1}) - V(x_k) \leq -x_k^T Q x_k - x_k^T \Gamma K T R K x_k \).

**Appendix B.2. A Common Lyapunov Function**

In view of the proof above, for given \((K_i, P_i)\) satisfying (10), the sets \( E_1, \ldots, E_m \) described in Assumption 2 can be found by reducing \( \alpha_i \in [0, \gamma_i) \) such that the following holds true
\[ \min_{x \in E_i} \psi_i(x) \geq 0, \forall i \in [1, m], \] (A8)
where, according to (A5),
\[ \psi_i(x) = x^T \Gamma_i x + (\tau_i^2 - 1)x^T A_{k_i}^T P_i A_{k_i} x - 2x^T A_{k_i}^T P_i \Phi_i(x) - \Phi_i^T(x) P_i \Phi_i(x), \]
and $P_L$ satisfying $\tau_i^2 A_{K,i}^T P_L A_{K,i} - P_L \leq \tau_i^2 A_{K,i}^T P_i A_{K,i} - P_i$ for all $i \in [1,m]$. Note that nonlinear optimization (A8) is similar to the optimization used in [5,25,26].
