ABSTRACT

Three radii are associated with a circle: the “geodesic radius” \( r^* \) which is the distance from circle’s center to its perimeter, the “circumferential radius” \( \tilde{r} \) which is the length of the perimeter divided by \( 2\pi \) and the “curvature radius” \( R \) which is circle’s curvature radius in the Frenet sense. In the flat Euclidean geometry it is \( r^* = \tilde{r} = R \), but in a curved space these three radii are different. I show that although Newton’s dynamics uses Euclidean geometry, its equations that describe circular motion in spherical gravity always unambiguously refer to one particular radius of the three — geodesic, circumferential, or curvature. For example, the gravitational force is given by \( F = -\frac{GMm}{\tilde{r}^2} \), and the centrifugal force by \( mv^2/R \). Building on this, I derive a Newtonian formula for the perihelion of Mercury advance.

Key words. celestial mechanics — perihelion of Mercury advance — curvature of space

1. Introduction

Newton’s theory of gravity was formulated in a flat, Euclidean 3-D space but its basic laws, i.e. the Poisson equation and the equation of motion,

\[
g^{ik}\nabla_i\nabla_k \Phi = -4\pi G \rho, \tag{1}
\]

\[
F_i = ma_i, \tag{2}
\]

make a perfect sense in the 3-D space with an arbitrary geometry \( g_{ik} \). Here, I will show that some of the geometrical concepts in a curved space naturally pop-up from the Newtonian dynamics. In particular, Newton’s dynamics knows about differences between the three radii of a circle: the geodesic radius \( r^* \), the circumferential radius \( \tilde{r} \), and the curvature radius \( R \) (shown in Figure 1 in the next Section, we give their formal definitions). Therefore, these radii may be measured by Newtonian dynamical experiments. In the flat, Euclidean space the three radii are equal, but in a space with a non-zero Gaussian curvature \( G \), they are different\(^1\). The Gaussian curvature may be calculated from the explicitly known relation \( G = \mathcal{G}(r^*, \tilde{r}) \), which means that it can be measured from Newtonian experiments. Then, the perihelion of the Mercury advance \( \Delta \phi \) may be explained in Newton’s theory because, as we will show later in this article, Newton’s theory predicts,

\[
\Delta \phi = -\pi \left( \frac{dG}{dr^*} \right)^2 r^6. \tag{3}
\]

\(^1\) The Gaussian curvature at a particular point of a 2-D surface is given by its two principal curvature radii \( \mathcal{G} = 1/(R_1 R_2) \). For a sphere with radius \( R \) it is \( \mathcal{G} = 1/(R^2) \), for a cylinder it is \( \mathcal{G} = 0 \). According to Gauss’s Theorem Egregium, the curvature \( \mathcal{G} \) may be determined by intrinsic geometry of the surface, with no reference to the external 3-D Euclidean space. Note that the dimension of the Gaussian curvature is \( 1/(\text{length})^2 \).
The circumferential radius of the circle equals $\tilde{r}$. This follows from
\[
\text{(circumferential radius)} \equiv \frac{1}{2\pi} \int_0^{2\pi} ds|_{\tau_r=\text{const}} = \frac{1}{2\pi} \int_0^{2\pi} \tilde{r} d\phi = \tilde{r}.
\] (6)

A unit tangent vector to a circle is defined by
\[
\tau^i = \frac{1}{r} \delta^i_\phi,
\] (7)
where $\delta^i_\phi$ is the Kronecker delta. The curvature radius $\mathcal{R}$ of a circle is defined by,
\[
\text{(curvature radius)} \equiv \left(\frac{d\tau^i}{ds}\right)^{-1/2} = \mathcal{R}.
\] (8)

This definition follows from the Frenet formula,
\[
\frac{d\tau^i}{ds} = -\frac{1}{\mathcal{R}} \lambda^i,
\] (9)
where $\lambda^i$ is a unit vector normal to the circle.

We will use later two useful formulae for the curvature of the circle $\mathcal{K} = 1/\mathcal{R}$, and for the Gaussian curvature $\mathcal{G}$ of the surface with the metric (4),
\[
\mathcal{K} = + \frac{1}{r} \left(\frac{d\tilde{r}}{dr}\right),
\] (10)
\[
\mathcal{G} = - \frac{1}{r^2} \left(\frac{d^2\tilde{r}}{dr^2}\right).
\] (11)

Formula (10) follows from (9). For derivation of (11) see e.g. Synge and Schild (1978) Section 3.4.

3. Equations of motion

Let us consider a curve in space given by a parametric equation,
\[
x^i = x^i(s),
\] (12)
where $x^i$ are coordinates in space, and $s$ is the length along the curve. If a body moves along this curve, its velocity equals,
\[
v^i = \frac{dx^i}{dt} = \frac{ds}{dt} \frac{dx^i}{ds} = v \tau^i.
\] (13)

Here $v = ds/dt$ is the speed of the body and $\tau^i = dx^i/ds$ is a unit vector tangent to the curve (12), i.e. the direction of motion. The acceleration may be calculated as follow,
\[
a^i = \frac{dx^i}{dt} = \frac{ds}{dt} \frac{d(\tau^i)}{ds} = v^2 \frac{d\tau^i}{ds} + \tau^i v \frac{dv}{ds}.
\] (14)

Assuming a particular of circular motion with constant velocity, $v = \text{const}$, and applying (14) to calculate the term in brackets, we arrive at
\[
a^i = v^2 \frac{1}{\mathcal{R}} \lambda^i,
\] (15)
which is the well known formula for the centrifugal acceleration.

Consider now a circular motion around a spherically symmetric center of gravity. The Newtonian equation of motion, $F^i = ma^i$, takes the form,
\[
-\nabla^i \Phi = v^2 \frac{1}{\mathcal{R}} \lambda^i,
\] (16)
where $F^i = -m\nabla^i \Phi$ is the gravitational force, and $\Phi$ is the gravitational potential. Three quantities characterize motion at a particular circular orbit: the angular velocity $\Omega$, the angular speed $v$, and the specific angular momentum $L$. They are related by,
\[
v = \tilde{r} \Omega,
\] (17)
\[
L = \tilde{r} v = \tilde{r}^2 \Omega.
\] (18)

Using (18), and multiplying its left and right side by $\lambda_i$, we transform the equation of motion (16) into a form which will be convenient later,
\[
\lambda_i \nabla^i \Phi = \frac{L^2}{\tilde{r}^2 \mathcal{R}}.
\] (19)

Let us remind that $\lambda^i$ is a unit, outside pointing, vector. Here "outside" has the absolute meaning — outside the center, in the direction to infinity. We will calculate the left-hand side of this equation in the next Section.

4. Newton’s gravity and Kepler’s law

In an empty space, the gravitational potential $\Phi$ obeys the Laplace equation,
\[
\nabla_i (\nabla^i \Phi) = 0.
\] (20)

Let us integrate (20) over the volume $V$ that is contained between two spheres, concentric with the gravity center, with sphere $S_1$ being inside sphere $S_2$. We transform the volume integral into the surface integral, using the Gauss theorem
\[
0 = \int_V \nabla_i (\nabla^i \Phi) dV = \int_{S_1} (\nabla^i \Phi) N_1^{(1)} dS + \int_{S_2} (\nabla^i \Phi) N_1^{(2)} dS.
\] (21)

The oriented surface elements on the spherical surfaces $S_1$ and $S_2$ may be written, respectively, as
\[
N_1^{(1)} dS = -\lambda_i dS, \quad N_1^{(2)} dS = +\lambda_i dS,
\] (22)
and therefore,
\[
\int_{S_1} (\nabla^i \Phi) \lambda_i dS = \int_{S_2} (\nabla^i \Phi) \lambda_i dS.
\] (23)

This means that the value integral is the same, say $S_0$, for all spheres around the gravity center. In addition, because of the spherical symmetry of the potential, the quantity $(\nabla^i \Phi) \lambda_i$ is constant over the sphere of integration. Thus,
\[
S_0 = (\nabla^i \Phi) \lambda_i \int dS = 4\pi \tilde{r}^2 (\nabla^i \Phi) \lambda_i,
\] and
\[
(\nabla^i \Phi) \lambda_i = \frac{S_0}{4\pi \tilde{r}^2} = \frac{GM}{\tilde{r}^2}.
\] (24)

Combining (21) with (19), we may finally write,
\[
L^2 = GM\mathcal{R}.
\] (25)
This is the Kepler Third Law. Using natural units for radius and frequency,
\[ R_G = \frac{GM}{c^2}, \]
\[ \Omega_G = \frac{c^3}{GM}, \]
we may write the formula for the Keplerian angular velocity as,
\[ \left( \frac{\Omega}{\Omega_G} \right)^2 = R_G^3 \left( \frac{R}{R_t} \right). \]

5. Epicyclic oscillations, the perihelion advance

Suppose that we slightly perturb a test-body on a circular orbit. This means that its angular momentum will not correspond to the Keplerian one, \( \mathcal{L}^2 \), but will be slightly different \( \mathcal{L}^2 + \delta \mathcal{L}^2 \). There will be also a small radial motion with velocity \( \delta \mathcal{L}_r \) and acceleration \( \ddot{\delta r}_r \). From (19) it follows that
\[ \frac{GM}{r^2} - \frac{\mathcal{L}^2 + \delta \mathcal{L}^2}{r^2 R} = (\ddot{\delta r}_r). \]
Keeping the first order term in equation (29), and using
\[ \delta \mathcal{L}^2 = \frac{d \mathcal{L}^2}{dr_r}(\delta r_r), \]
we arrive at the simple harmonic oscillator equation,
\[ \omega^2(\delta r_r) + (\ddot{\delta r}_r) = 0, \]
where \( \omega \) is the radial epicyclic frequency,
\[ \omega^2 = \frac{1}{r^2 R} \left( \frac{d \mathcal{L}^2}{dr_r} \right). \]
Using equations (25), (26) and (27), we may write the expression for the epicyclic frequency in the form,
\[ \left( \frac{\omega}{\Omega_G} \right)^2 = - \frac{1}{r^2 R} \left( \frac{d \mathcal{L}^2}{dr_r} \right) \left( \frac{R_G}{R} \right)^3. \]

6. Surface of constant curvature

A 2-sphere with radius \( R \) has a constant Gauss curvature \( G = 1/R^2 \) and the metric,
\[ ds^2 = dr^2 + \tilde{r}^2 d\phi^2 = dr_r^2 + R^2 \sin^2 \left( \frac{r_s}{R} \right) d\phi^2 \]
\[ \tilde{r} = r_s \left( 1 - \frac{1}{6} \left( \frac{r_s}{R} \right)^2 + \ldots \right). \]
Similarly, a 2-space with constant negative curvature \( G = -1/R^2 \) has the metric,
\[ ds^2 = dr^2 + \tilde{r}^2 d\phi^2 = dr_r^2 + R^2 \sin^2 \left( \frac{r_s}{R} \right) d\phi^2. \]
This means that, in a space with small constant (positive or negative) curvature,
\[ \alpha = 0, \]
and therefore \( \Delta \phi/2\pi = 0 \). There is no perihelion precession in spaces with constant (positive or negative) curvature.

7. Discussion and conclusions

Newton’s theory of gravity was formulated in a flat, Euclidean 3-D space but its basic laws, i.e. the Poisson equation and the equation of motion, make a perfect sense in the 3-D space with an arbitrary geometry \( g_{ik} \). In particular, Newtonian dynamics allows to measure the circumferential \( \tilde{r} \) and curvature \( R \) radii of circular orbits by measuring the gravitational \( F_G \) and centrifugal \( F_C \) forces,
\[ F_G = -\frac{GMm}{\tilde{r}^2}, \quad F_C = \frac{m v^2}{R}. \]
If \( \tilde{r} \neq R \), it is \( G \neq 0 \). One may measure the Gaussian curvature of a surface at different circular orbits and find \( G = \mathcal{G}(r_s) \) using formulae (10) and (11). The predicted value of the perihelion advance is \( \Delta \phi/2\pi = -(1/2)(d \mathcal{G}/dr_r)^2 \tilde{r}^6 \).

Acknowledgements. Calculations presented in this article have been done during author’s treatment at the Gastroenterology and Transplantology Ward of the MSW Hospital in Warsaw, before and after his surgery. The author thanks Dr Andrzej Otto who has performed the surgery. This work has been supported by the Polish National Health Foundation (NFZ) and the NCN UMO-2011/01/B/ST9/05439 grant.

I would like to thank Maciej Wielgus for checking all calculations presented here.
