Background: Long non-coding RNAs nowadays emerge as important biomarkers or potential therapeutic targets discussed in human cancers. Among them, maternally expressed gene 3 (MEG3) is known to be decreased in a variety of malignancies, and this affects tumor cellular proliferation, migration, and invasion.

Materials and methods: Quantitative real-time PCR was performed to detect the expression of MEG3 in normal cervical epithelium, cervical intraepithelial neoplasia, and cervical squamous cell carcinoma tissues. Gain-of-function and loss-of-function studies were carried out to determine the effect of MEG3 on cell survival, migration, and invasion, which was evaluated by CCK-8 assay, wound healing assay, and transwell assays. mRNA and protein expression of Rac1 were finally determined by quantitative real-time PCR and immunoblotting, respectively.

Results: The expression of MEG3 was downregulated in cervical intraepithelial neoplasia and squamous cell carcinoma tissues. Forced expression of MEG3 led to reduced abilities of cell survival. Overexpression of MEG3 also inhibited cell migration and invasion in vitro. Cell proliferation marker and EMT markers were changed consistently with the phenotype. In addition, Rac1 was inhibited by MEG3 overexpression at both transcriptional and translational levels. Also, Rac1 could rescue the phenotype caused by long non-coding RNA MEG3. And, it negatively correlated with MEG3 expression in cervical cancer (CC) tissues and cell lines.

Conclusion: Our findings revealed that MEG3 could negatively regulate CC cell survival, migration, and invasion. It might serve as an important target for CC treatment.

Keywords: MEG3, cervical cancer, survival, migration and invasion, Rac1

Introduction
According to the statistics, cervical cancer (CC) originating from the female reproductive system is the third most common malignancy and fourth leading cause of cancer-related death in women all around the world.1,2 Every year there are over 500,000 cases diagnosed as CC and approximately 200,000 deaths caused by CC in the world, with the majority in developing countries.2 Long-term infection by human papillomavirus (HPV) is an important factor for the initiation of CC. However, existing CC screening toward HPV has not obviously brought down the diagnostic rate of this disease, indicating other factors also contribute to the development of CC.3–5 CC could be cured by surgery, radiotherapy, and concurrent platinum-based chemotherapy. Nevertheless, some cases develop recurrence, mainly attributed to metastasis, and receive bad outcomes.6 Therefore, novel and efficient therapeutic targets are required for its treatment.

Recent research progress in the human genome has found non-coding RNAs (ncRNAs) transcribed from <2% of the total genome with limited or no protein-coding capacity
due to lack of open reading frames (ORFs). Long non-coding RNAs (lncRNAs) are a large subgroup of ncRNAs with more than 200nt in length, and not necessarily conserved among different species. The function of most lncRNAs remains obscure, and their relevance to human diseases is largely undefined. Increasing evidence has demonstrated that some lncRNAs play vital roles in basic cellular functions, including cell proliferation, survival, differentiation, motility and apoptosis, and serve as potential oncogenes or tumor suppressors in cancers. However, the regulation of most lncRNAs and their exact mechanisms in CC are not clear. Exploration of the function and involvement of lncRNA in CC would improve its therapy and enable new targets to be identified.

Maternally expressed gene 3 (MEG3), located on human chromosome 14q32, is a maternally expressed imprinted gene expressed in many normal tissues. It has been reported that MEG3 functions as a tumor suppressor since it is disrupted in various human cancers by epigenetic regulation. In CC, antitumoral activity has been mentioned in previous studies, like inhibiting cell proliferation and inducing apoptosis. However, whether it is involved in migration and invasion remains elusive. Rac family small GTPase 1 (Rac1) encodes a GTPase which belongs to the RAS superfamily of small GTP-binding proteins. Studies have established that Rac1 regulates a diverse array of cellular events in cancer, such as controlling cell growth, cytoskeletal reorganization, and metastasis. Herein, through a series of experiments, we verified that MEG3 is decreased in CC samples, and suppresses cell survival, migration, and invasion by targeting Rac1. Our findings strengthen the antitumoral role of MEG3 in CC.

Materials and methods

Patients and tissues

A total of 20 normal cervical epithelium (NCE) tissue samples, 20 cervical intraepithelial neoplasia (CIN) tissue samples, and 20 cervical squamous cell carcinoma (SCC) tissue samples were obtained from patients in the 1st Affiliated Hospital of Fujian Medical University from January 2015 to December 2016. The study was approved by the Medical Ethics Committee of the 1st Affiliated Hospital of Fujian Medical University. Written informed consent from all patients was obtained prior to participation in the study. All samples were immediately snap-frozen, and kept at −80°C for quantitative real-time PCR (qRT-PCR) until use.

Cell culture

Non-tumoral human cervical epithelial (HcerEpic) cells and human cervical carcinoma cell lines C-33A, C4-1, Caski, SiHa, and Hela were obtained from the American Type Culture Collection (ATCC, Manassas, VA, USA) or the Chinese Academy of Sciences Cell Bank (Shanghai, China). Cells were cultured in 1,640 or DMEM medium (HyClone, Victoria, Australia) supplemented with 10% FBS (HyClone), 100 units/ml of penicillin (Gibco®, Thermo Fisher Scientific, Waltham, MA, USA), and 100 μg/mL streptomycin (Gibco, Thermo Fisher Scientific) at 37°C, in a humidified atmosphere containing 5% CO₂ in an incubator.

qRT-PCR

Total RNAs were isolated from cells by Trizol reagent (Thermo Fisher Scientific), and reverse transcriptions were performed by GoScript™ Reverse Transcription System (Promega Corporation, Fitchburg, WI, USA) as per the manufacturer’s instructions. qRT-PCR was performed using SYBR® Green Realtime PCR Master Mix (Toyobo, Osaka, Japan) on an Applied Biosystems 7,500 Real-Time PCR system (Thermo Fisher Scientific). The U6 small RNA or β-actin mRNA was used as internal controls of lncRNAs or genes. All reactions were run in triplicate. The 2^−ΔΔCt method was used to calculate the relative expression of each reaction. Primers used for amplification are provided as follows:

| lncRNA MEG3       | Forward: 5′-GCCAAGCTTCTGAAAGGCC-3′ | Reverse: 5′-TTCCACGGAATGAGCGAGTC-3′ |
| U6 small RNA      | Forward: 5′-CGCTTCGCGACGACATACA-3′ | Reverse: 5′-TCACGATTTTGCCTGTC-3′  |
| Rac1              | Forward: 5′-AGGAAAGCGGACATATTAGTCC-3′ | Reverse: 5′-CAGCTTTTCGCTGCTGTC-3′ |
| β-actin           | Forward: 5′-TGACGGGGTCACCCACACTGC-3′ | Reverse: 5′-CTAGAACCTTTGCGGTGGAC-3′ |

Plasmids, siRNAs, and transfections

Overexpression of lncRNA MEG3 plasmid and Rac1 plasmid were from GeneChem Company (Shanghai, China). Empty vector was used as a control. Two MEG3 siRNAs (simeG3 #1, and siMEG3 #2) and scrambled negative control siRNA (NC) were purchased from GenePharma (Shanghai, China). Transfections were performed by using Lipofectamine 2000
Transfection Reagent (Thermo Fisher Scientific) according to the manufacturer’s instructions.

**Cell proliferation assay**
Cells were seeded at a density of $3 \times 10^3$ cells per well in a 96-well plate containing 100 µL 1,640 or DMEM full medium. Cell Counting Kit-8 (Dojindo, Kumamoto, Japan) reagents were added at 1 day, 2 days, 3 days, 4 days and 5 days after seeding (0 day) and incubated at $37^\circ C$ for 2 hours. The data of OD 450 were measured by a microplate reader (Molecular Devices LLC, Sunnyvale, CA, USA). Each experiment was performed at least three times with six replicates.

**Wound healing assay**
Cervical cells were seeded into 6-well plates. Cells were scraped with a sterile 200 µL micropipette tip when grown to 90% confluent. The wounded monolayers were washed with phosphate buffer solution (PBS) twice to remove cell debris. The distance between the two edges of the wound was calculated at five different positions. After 48 hours, the distance between the two edges was measured again at each position.

**Transwell assay**
Transwell chambers (Costar®, Corning Incorporated, Corning, NY, USA) with 8 µm pore polycarbonate filters were coated with matrigel (BD Biosciences, San Jose, CA, USA). Into the upper chambers in serum-free medium, $3 \times 10^4$ cells were seeded at a volume of 200 µL/well. The lower chamber contained 500 µL medium with 10% FBS as a chemoattractant. Cells on the upper surface of the chamber were removed by a cotton swab after incubating for 48 hours at $37^\circ C$ with 5% CO$_2$. Traversed cells on the lower side of the filter were fixed with 4% paraformaldehyde and stained with 0.25% crystal violet solution. Invaded cells in the lower chamber were counted and photographed using phase contrast microscopy. The numbers of invaded cells were determined by photographing in five random views per chamber at 200× magnification.

**Immunoblotting**
Cells were collected and resuspended in RIPA lysis buffer (Beyotime, Beijing, China). A total of 30 µg of total protein was loaded and separated on SDS-polyacrylamide gels (SDS-PAGE) and transferred onto polyvinylidene difluoride membranes (Millipore, Billerica, MA, USA). The membranes were blocked with 5% non-fat milk for 1 hour at room temperature and incubated with specific primary antibodies at $4^\circ C$ overnight. The specific antibodies for Rac1, PCNA, E-cadherin, N-cadherin, vimentin, and β-actin proteins were from Cell Signaling Technology (Cell Signaling Technology Inc., Danvers, MA, USA). The membranes were incubated with the specific HRP-conjugated secondary antibodies (Beyotime) for 1 hour at room temperature. ECL chromogenic substrate (Beyotime) was used to visualize the bands. α-tubulin was used as an internal control.

**Statistical analysis**
Statistical analyses were performed using SAS v9.2. All graphs were made using GraphPad software v6.0. All data from three independent experiments were expressed as mean ± SD. Differences between groups were performed by two-tailed Student’s t-test. The relationship between lncRNA MEG3 and Rac1 expression was performed by linear regression. A $P$-value of $<0.05$ was considered statistically significant.

**Results**
**lncRNA MEG3 is downregulated in CC tissues and cell lines**
Firstly, to understand the function of lncRNA MEG3 in CC, we detected the expression of MEG3 in 20 cases of NCE, 20 cases of CIN, and 20 cases of cervical SCC obtained from individuals with informed consent. The qRT-PCR result showed that MEG3 expression was significantly downregulated in CINs compared with NCEs and further declined in SCCs, suggesting a disease progression-dependent decrease (Figure 1A). On the other hand, qRT-PCR detection in five CC cell lines (C-33A, C-41, Caski, SiHa, and Hela) also confirmed its downregulation, compared with non-tumoral human cervical epithelial HcerEpic cells (Figure 1B). These findings indicated that MEG3 was decreased in CC and suggested its antitumoral effects.

**lncRNA MEG3 inhibits CC cell survival**
Based on the above results, we questioned whether lncRNA MEG3 could impact on CC cell survival. We mainly utilized CCK-8 assay to evaluate cell survival, namely, cell viability. As shown in Figure 2A, we obtained successfully MEG3 overexpressing subcell lines in Hela and SiHa. Meanwhile, we found that MEG3 overexpression led to an obviously lower cell survival rate in both cell lines (Figure 2B). Moreover, the proliferation marker PCNA showed significant decrease after MEG3 overexpression.
in both cells (Figure 2C). This finding is in line with our forecast, because its antitumoral activity has been mentioned in previous studies in CC, including inhibiting cell proliferation and inducing apoptosis.\textsuperscript{16,17}

**IncrNA MEG3 inhibits migration and invasion of CC cells**

Considering migration and invasion are vital steps guiding cancer cell metastasis, we then sought to determine whether
lncRNA MEG3 also impacted on these two processes of CC cells in vitro. We knocked down the intracellular MEG3 by two independent siRNAs. As shown in Figure 3A and B, loss of MEG3 significantly improved migration assessed by wound healing assay and invasion by transwell assays in SiHa cells. Besides, MEG3 overexpression in Hela cells inhibited invasion in vitro (Figure 3C). Immunoblotting assay was performed to detect the EMT markers changing. The results showed that E-cadherin was decreased while N-cadherin and vimentin increased significantly after knocking down

of MEG3. Also, overexpressing of MEG3 did the opposite (Figure 3D). This finding was the first time in CC. Our results put forward another important role of lncRNA MEG3 in suppressing cell metastasis of CC cells.

lncRNA MEG3 stimulates repression of Rac1
It's clear that lncRNAs modulate hundreds of mRNA targets, resulting in global changes in the cellular phenotype of cells. Combining with previous reports and online targeting predicting resources, we found that lncRNA MEG3 could theoretically target Rac1, a key gene regulating cell survival and metastasis. Figure 4A showed the diagram of the binding sequence of MEG3-RAC1 by NCBI blast online tools. Our following qRT-PCR and immunoblotting assay verified this prediction, which was that MEG3 overexpression induced repression of Rac1 mRNA and protein expression (Figure 4B and C). Next, we found Rac1 expression was significantly upregulated in CINs compared with NCEs and further increased in SCCs (Figure 4D), and it was negatively correlated with MEG3 level in SCC tissues (Figure 4E). Furthermore, we found that Rac1 was significantly upregulated

**Figure 4** lncRNA MEG3 negatively regulates Rac1 gene expression.

In the abovementioned CC cell lines (Figure 4F), whose expression exhibited a clear negative linear correlation with MEG3 levels in these cell lines (P<0.05, Figure 4G). This finding indicated that MEG3 could exert tumor inhibitory effects on CC cells via targeting of Rac1.

**IncRNA MEG3 functions in cell survival and invasion through Rac1 pathway**

In order to evaluate whether Rac1 could reverse the inhibitory effect caused by MEG3 overexpression, rescue experiments were performed. Firstly, we overexpressed Rac1 in MEG3 overexpressing Hela cells, as shown in Figure 5A. Also, we found that Rac1 overexpression could increase the cell survival and invasion by CCK-8 and transwell assay, compared to the MEG3 overexpressing group (Figure 5B and C). This finding indicated that MEG3 did function in cell survival and invasion through the Rac1 pathway, at least partly.

**Discussion**

lncRNAs, once considered as transcription noise, now appear as vital regulators in a large range of biological processes as mentioned above.9–11 More than 3,000 human lncRNAs have been identified, however, less than 1% of them have been characterized.20 They exert diverse actions on cancer cells through distinct mechanisms, such as imprinting, chromosome dosage-compensation, epigenetic modulation, RNA splicing, nuclear, and cytoplasmic trafficking.21 To date, many lncRNAs have been found to be involved in CC progression and highlighted as novel targets for diagnosis, as well as prognosis, and future targeted therapies for CC.22

In this study, we characterized that IncRNA MEG3 was downregulated in CIN and further decreased in SCC tissues, compared to NCE tissues. Although it has been confirmed by two groups,17,23 our findings further validated its expression pattern in CC and strongly suggested its antitumoral role in CC. In fact, we learned from lines of evidence that MEG3 expression is controlled by epigenetic regulation, that is, prevalent CpG methylation results in its low expression in some cancers.24,25 Also, other studies in CC have validated the promoter hypermethylation of MEG3 in both plasma and tissues of CC patients,26,27 fully supporting its downregulation in CC. On the other hand, we confirmed its low expression in several CC cell lines, compared with the non-tumoral HcerEpic cells.

In order to characterize the exact role of MEG3 in CC, we performed overexpression assays in both CC cell lines,
Hela and SiHa. As predicted, forced expressing of MEG3 suppressed cell survival as revealed by CCK-8 assay. This was not surprising, since it has been found by Zhang’s study. Importantly, we intriguingly found that knockdown of MEG3 promoted migration and invasion, while overexpression of MEG3 inhibited invasion of CC cells. Also, cell proliferation and EMT markers were changed consistently with the phenotype. This finding is the first time in CC, although it has been identified in some other malignancies. Further in vivo data are needed to fully confirm this result.

Finally, we identified Rac1 as an important target of IncRNA MEG3 in CC, since MEG3 overexpression dramatically reduced its mRNA and protein levels in both Hela and SiHa cells. Wang’s study in thyroid carcinoma firstly validated Rac1 as an existing target of MEG3 by specifically base pairing to its 3′-UTR and leading to transcription repression.28 Herein, we also support the targeting of Rac1 by MEG3. As a well-known Rho GTPase, Rac1 contributes to cancer cell survival and metastasis through various signaling pathways. And, the rescue experiments in our study confirm that MEG3 functions through Rac1 pathways. Therefore, our findings enriched the mechanism of MEG3 in determining CC cell behaviors, at least through targeting Rac1.

Conclusion
Our data suggest an important role of IncRNA MEG3 in the molecular biology of CC, especially in highlighting its anti-migration and anti-invasion abilities, and implicating the potential application of MEG3 in CC therapy in the future.
