Abstract

We study twist-field representations of the W-algebras and generalize the construction of the corresponding vertex operators to D- and B-series. We demonstrate how the computation of characters of such representations leads to the nontrivial identities involving lattice theta-functions. We propose a construction of their exact conformal blocks, which for D-series expresses them in terms of geometric data of corresponding Prym variety.

1 Introduction

Representation theory for the W-algebras [1] is still the subject with many open questions. These questions often arise in the context of a two-dimensional conformal theory (CFT) with extended symmetry, and due to a nontrivial recently found correspondence [2, 3, 4, 5] may be important for multidimensional supersymmetric gauge theories.

The main object of this study is a conformal block. Generally there is a space of conformal blocks: the space of all functionals on the product of Verma modules at given points of the Riemann surface that solve Ward identities (see e.g. [6] where the language of coinvariants was used). Such spaces form a bundle over moduli space of curves with marked points.

However, in order to construct physical correlation functions one should be able to extract particular concrete section of this bundle. Usually the corresponding functionals are computed on the highest weights in each of the Verma modules. For the Virasoro algebra the conformal blocks are specified by definite intermediate dimensions, or, equivalently, by
the asymptotic behavior of the conformal block on the boundary of the moduli space \[7\]. It turns out that for the general \(W_N\) algebra it is no longer enough to do this by fixing quantum numbers in the intermediate channels. Even for three points on sphere, the vector space of conformal blocks becomes infinite dimensional for \(W_N\) algebras with \(N > 2\).

However, for certain particular cases this conformal block can be constructed explicitly applying some extra machinery. In what follows we first restrict ourselves to the case of integer and sometimes half-integer Virasoro central charges, when representations \(W\)-algebras are more directly related to the representations of the corresponding Kac-Moody (KM) algebras (of level \(k = 1\), and the corresponding field theories can be directly described by free fields \[8\].

One of the recent methods \[9\] reduces the problem here to a Riemann-Hilbert problem, arising in the context of the isomonodromy/CFT correspondence \[10, 11, 12\]. The key idea of this approach is to extract concrete conformal block by implying condition that it has predictable monodromies after insertion of the simplest degenerate fields, or fermions. Morally saying, it means that we fix the 3-point blocks as eigenvectors of Verlinde loop operators and parameterize them by monodromy data.

Even in such situation, in case of generic monodromies one cannot write explicit formula for conformal block. Below, following \[13\], we are going to restrict ourselves to the case of so-called twist fields \[14\], corresponding to quasi-permutation monodromies, when the representations of the \(W\)-algebras become related to the twisted representations of the corresponding KM algebras \[15, 16\].

The paper is organized as follows. We start from the formulation of the representations of KM and \(W\)-algebras in terms of free bosons and fermions, remind first the \(GL(N)\) case and extend it to the \(D-\) and \(B-\) series, using real fermions. We define then the twist field representations corresponding to the elements of Cartan’s normalizer \(g \in N_G(h)\) together with some extra data (to be denoted as \(\check{g}\) and \(\tilde{g}\), see the details in Sect. \[3\] below). Bosonization of twist fields essentially depends on the conjugacy classes in the \(N_G(h)\). We classify such classes for \(G = GL(N)\) and \(G = O(n)\) (for \(n = 2N\) and \(n = 2N + 1\)) and define the twist fields \(\mathcal{O}_g\) in terms of the boundary conditions and singularity structure in corresponding free theory.

Bosonization rules allow to compute easily the characters \(\chi_{\check{g}}(q)\) of the corresponding representations. For the twist fields of “\(GL(N)\) type” this goes back to the old results of Al. Zamolodchikov and V. Knizhnik, and we develop here similar technique in the case of real fermions and another class of twist fields, arising in \(D-\) and \(B-\) series. The character formulas include summations over the root lattices, reflecting the fact that we deal here with the class of lattice vertex algebras. Dependently of the conjugacy class \(g \in N_G(h)\) of a twist field the lattice can be reduced to its projection to the Weyl-invariant part, in this case the “smaller” lattice theta functions show up, or we find even a kind of “exchange” between those for \(D-\) and \(B-\) series.

If two different elements \(g_{1,2} \in N_G(h)\) are nevertheless conjugated \(g_1 \sim g_2\) in \(G\) (but not in \(N_G(h)\)), this gives for appropriate additional data a nontrivial identity \(\chi_{\check{g}_1}(q) = \chi_{\check{g}_2}(q)\) between two characters, involving lattice theta-functions. Such character identities go back to 1970’s (see \[17, 18\]) and even to Gauss, but our derivation gives probably the new ones, involving in particular the theta functions for \(D-\) and \(B\)-root lattices.

\[1\]To prevent the reader’s confusion we should notice that “twist field representation” is different from “twisted representation”: the latter one implies that the algebra itself is changed (twisted), whereas the first one only reflects the way – how this representation was constructed.
We propose construction of the exact conformal blocks of the twist fields for W-algebras of \(D\)-series, generalizing approach of \([14, 13]\), and obtain an explicit formula, expressing multipoint blocks in terms of the algebro-geometric objects on the branched cover with extra involution.

2 W-algebras and KM algebras at level one

2.1 Boson-fermion construction for GL(N)

We start from standard complex fermions

\[
\psi^*_\alpha(z) = \sum_{p \in \frac{1}{2} + \mathbb{Z}} \frac{\psi^*_{\alpha,p}}{z^{p+\frac{1}{2}}}, \quad \psi_\alpha(z) = \sum_{p \in \frac{1}{2} + \mathbb{Z}} \frac{\psi_{\alpha,p}}{z^{p+\frac{1}{2}}}
\]

(2.1)

with the operator product expansions (OPE’s)

\[
\psi^*_\alpha(z)\psi_\beta(w) = -\psi_\beta(w)\psi^*_\alpha(z) = \frac{\delta_{\alpha\beta}}{z-w} + \text{reg.}
\]

\[
\psi_\alpha(z)\psi_\beta(w) = \psi^*_\alpha(z)\psi^*_\beta(w) = \text{reg.}
\]

(2.2)

equivalent to the following anticommutation relations

\[
\{\psi_{\alpha,p}^*, \psi_{\beta,q}\} = \delta_{\alpha\beta}\delta_{p+q,0}, \quad \{\psi_{\alpha,p}, \psi_{\beta,q}\} = \{\psi_{\alpha,p}^*, \psi_{\beta,q}^*\} = 0, \quad p, q \in \frac{1}{2} + \mathbb{Z}
\]

(2.3)

One can introduce the Kac-Moody \(\hat{\text{gl}}(N)_1\) algebra by the currents

\[
J_{\alpha\beta}(z) = \psi^*_\alpha(z)\psi_\beta(z)
\]

(2.4)

where the free fermion normal ordering moves all \(\{\psi_r\}\) and \(\{\psi_r^*\}\) with \(r > 0\) to the right.

These currents have standard OPE’s:

\[
J_{\alpha\beta}(z)J_{\gamma\delta}(w) = \frac{\delta_{\beta\gamma}\delta_{\alpha\delta}}{(z-w)^2} + \frac{\delta_{\beta\gamma}J_{\alpha\delta}(w) - \delta_{\alpha\delta}J_{\beta\gamma}(w)}{z-w} + \text{reg.}
\]

(2.5)

and when expanded into the (integer!) powers of \(z\)

\[
J_{\alpha\beta}(z) = \sum_{n \in \mathbb{Z}} \frac{J_{\alpha\beta,n}}{z^{n+1}}
\]

(2.6)

we get the standard Lie-algebra commutation relations

\[
[J_{\alpha\beta,n}, J_{\gamma\delta,m}] = n\delta_{n+m,0}\delta_{\beta\gamma}\delta_{\alpha\delta} + \delta_{\beta\gamma}J_{\alpha\delta,m+n} - \delta_{\alpha\delta}J_{\beta\gamma,m+n}, \quad n, m \in \mathbb{Z}
\]

(2.7)

This set contains zero modes \(J_{\alpha\beta,0}\), generating the subalgebra \(\text{gl}(N) \subset \hat{\text{gl}}(N)_1\). The \(W(\text{gl}(N)) = W_N \oplus H\) algebra can be defined in a standard way – as a commutant of \(\text{gl}(N)\) in the (completion of the) universal enveloping algebra \(U(\hat{\text{gl}}(N)_1)\).

\(^2\)Here \(H = \hat{\text{gl}}(1)_1\) is the Heisenberg algebra, and \(W_N = W(\text{sl}(N))\).
The basis of the generators of $W(\mathfrak{gl}(N)) = W_N \oplus H$ algebra can be chosen in several different ways. In what follows the most convenient for our purposes is to use fermionic bilinears
\[ \sum_{\alpha = 1}^{N} \psi^*_\alpha (z + \frac{1}{2}t) \psi_\alpha (z - \frac{1}{2}t) = \frac{N}{t} + \sum_{k=1}^{\infty} \frac{t^{k-1}}{(k-1)!} U_k(z) \] \hspace{1cm} (2.8)
or, using the Hirota derivative $D^k_z f(z) \cdot g(z) = (\partial_{z_1} - \partial_{z_2})^n f(z_1)g(z_2)|_{z_1 = z_2 = z}$,
\[ U_k(z) = D^{k-1}_z \sum_{\alpha = 1}^{N} : \psi^*_\alpha (z) \cdot \psi_\alpha (z) : \] \hspace{1cm} (2.9)
while another useful basis is the bosonic representation
\[ W_k(z) = \sum_{\alpha_1 < \ldots < \alpha_k} : J_{\alpha_1 \alpha_1} (z) \ldots J_{\alpha_k \alpha_k} (z) : \equiv \sum_{\alpha_1 < \ldots < \alpha_k} : J_{\alpha_1} (z) \ldots J_{\alpha_k} (z) : \] \hspace{1cm} (2.10)

The formula [2.10] is equivalent to quantum Miura transform from [1]. To explain that the formula [2.9] is actually equivalent to [2.10] one can use description of $W(\mathfrak{gl}(N))$ as centralizer of screening operators, which coincide with $\mathfrak{gl}(N)$ in this case. It is already proven that [2.10] is centralizer of screening operators [20], so it remains to show that [2.9] is centralizer as well, what can be done in several steps:

1. Consider all normally-ordered fermionic monomials $\prod_i \partial^{k_i} \psi_{\alpha_i} (z) \prod_i \partial^{l_i} \psi^*_{\beta_i} (z) :$, which transform as tensors under the action of $GL(N)$. By First fundamental theorem of invariant theory [21] the only invariants in such representation are given by all possible contractions, so they can be written as $\prod_i (\sum \partial^{k_i} \psi_{\alpha_i} (z) \partial^{l_i} \psi^*_{\beta_i} (z)) :$.

2. Any such expression can be obtained by taking regular products (denoted by brackets) of the “elementary elements” $\sum \partial^{k_i} \psi_{\alpha_i} (z) \partial^{l_i} \psi^*_{\alpha_i} (z) :$, since
\[ \left( \prod_i \sum_{\alpha} \partial^{k_i} \psi_{\alpha_i} (z) \partial^{l_i} \psi^*_{\alpha_i} (z) : \sum_{\beta} \partial^{k} \psi_{\beta} (z) \partial^{l} \psi^*_{\beta} (z) : \right) = \prod_i \sum_{\alpha} \partial^{k_i} \psi_{\alpha_i} (z) \partial^{l_i} \psi^*_{\alpha_i} (z) \sum_{\beta} \partial^{k} \psi_{\beta} (z) \partial^{l} \psi^*_{\beta} (z) : + \text{lower terms in } \psi, \psi^* \] \hspace{1cm} (2.11)

Therefore one can perform this procedure iteratively and express everything as regular products of bilinears.

3. Any element $\sum \partial^{k} \psi_{\alpha} (z) \partial^{l} \psi^*_{\alpha} (z) :$ can be expressed as a linear combination of $\partial^{l'+1} U_{k'}(z)$ for different $l'$ and $k'$ with $l' + k' = l + k$.

Hence, the generators $\{ U_k(z) \}$ are expressible in terms of $\{ W_k(z) \}$ (and vice versa) by some non-linear triangular transformations, but we do not need here these explicit formulas.\(^3\)

\(^3\) The fact, that nonlinear W-algebra generators can be expressed through just bilinear fermionic expressions is well-known, and was already exploited in [2] [14] (see also [19] and references therein).
Formally there is an infinite number of generators in (2.8) and (2.9), since all of them are expressed in terms of $N$ generators (2.10), they are not independent: we have

$$U_{N+n}(z) = P_n(\{Q^k U_{1\leq N}\})$$

(2.12)

for some polynomials $\{P_n\}$, and this is the origin of the non-linearity of the W-algebra [19]. The relation between fermions and bosons is given by well-known [8, 22] bosonization formulas

$$\psi^*_\alpha(z) = \exp \left( -\sum_{n<0} \frac{J_{\alpha,n}}{nz^n} \right) \exp \left( -\sum_{n>0} \frac{J_{\alpha,n}}{nz^n} \right) e^{Q_\alpha z} J_{\alpha,0} \epsilon_\alpha(J_0) = e^{i\varphi_{\alpha,\beta}(z)} e^{Q_\alpha z} J_{\alpha,0} \epsilon_\alpha(J_0)$$

$$\psi_\alpha(z) = \exp \left( \sum_{n<0} \frac{J_{\alpha,n}}{nz^n} \right) \exp \left( \sum_{n>0} \frac{J_{\alpha,n}}{nz^n} \right) e^{-Q_\alpha z} J_{\alpha,0} \epsilon_\alpha(J_0) = e^{-i\varphi_{\alpha,\beta}(z)} e^{-Q_\alpha z} J_{\alpha,0} \epsilon_\alpha(J_0)$$

(2.13)

where $\epsilon_\alpha(J_0) = \prod_{\beta=1}^{\alpha-1} (-1)^{J_{0,\beta}}$ and diagonal $J_{\alpha,\alpha} \equiv J_{\alpha,0}$ form the Heisenberg algebra

$$[J_{\alpha,n}, J_{\beta,m}] = n\delta_{\alpha\beta}\delta_{m+n,0}, \quad [J_{0,\alpha}, Q_\beta] = \delta_{\alpha\beta}$$

(2.14)

One can also express all other generators in terms of (positive and negative parts of) the bosons

$$i\varphi_{+,\alpha}(z) = -\sum_{n>0} \frac{J_{\alpha,n}}{nz^n}, \quad i\varphi_{-,\alpha}(z) = -\sum_{n<0} \frac{J_{\alpha,n}}{nz^n}$$

(2.15)

namely

$$J_{\alpha\beta}(z) = e^{i\varphi_{-,\alpha} - i\varphi_{-,\beta}} e^{i\varphi_{+,\alpha} - i\varphi_{+,\beta}} e^{Q_\alpha Q_\beta z} J_{\alpha,0} J_{\beta,0} (-1)^{\frac{1}{2}} \sum_{\gamma=\alpha-1}^{\beta} J_{\gamma,0 + \theta(\beta-\alpha)}, \quad \alpha \neq \beta$$

$$J_{\alpha\alpha}(z) = J_{\alpha}(z) = i\partial \varphi_{+,\alpha}(z) + i\partial \varphi_{-,\alpha}(z)$$

(2.16)

### 2.2 Real fermions for $D$- and $B$- series

Now we can almost repeat the same construction for the orthogonal series, $B_N$ and $D_N$, which correspond to the W-algebras $W(\mathfrak{so}(2N+1))$ and $W(\mathfrak{so}(2N))$, respectively. The corresponding Kac-Moody algebras at level one can be realized in terms of the real fermions (see e.g. [23]) with the OPE’s

$$\Psi_i(z) \Psi_j(w) = \frac{\delta_{ij}}{z-w} + \text{reg.}, \quad i, j = 1, \ldots, n$$

(2.17)

(here dependently on the case we put either $n = 2N$ or $n = 2N+1$), which corresponds to anti-commutation relations

$$\{\Psi_i, \Psi_j\} = \delta_{ij} \delta_{p+q,0}, \quad p, q \in \frac{1}{2} + \mathbb{Z}$$

(2.18)

One can say that these OPE’s and commutation relations are defined by the metrics on $n$-dimensional space given by $\delta_{ij}$, or symbolically by $ds^2 = \sum_{i=1}^{n} d\Psi_i^2$. The Kac-Moody currents are again expressed by bilinear combinations

$$J^{(1)}_{ik}(z) = :\Psi_i(z)\Psi_j(z)$$

(2.19)
and satisfy usual commutation relations together with \( J_{ij}^{(1)}(z) = -J_{ji}^{(1)}(z) \). It is also convenient to pass to the complexified fermions (\( \alpha = 1, \ldots, N \))

\[
\psi^*_\alpha(z) = \frac{1}{\sqrt{2}}(\Psi_{2\alpha-1}(z) + i\Psi_{2\alpha}(z)), \quad \psi_\alpha(z) = \frac{1}{\sqrt{2}}(\Psi_{2\alpha-1}(z) - i\Psi_{2\alpha}(z))
\]  

(2.20)

which due to (2.17) have the standard OPE’s given by (2.2). Let us point out that \( B_N \)-series \( (i, j = 1, \ldots, 2N + 1) \) differs from \( D_N \)-series \( (i, j = 1, \ldots, 2N) \) by remaining single real fermion \( \Psi_{2N+1}(z) = \Psi(z) \).

Using the complexified fermions the generators (2.19) can be re-written as

\[
J_{\alpha\beta} =: \psi^*_\alpha(z)\psi_\beta(z) := \frac{1}{2}(J_{1,2\alpha-1,2\beta-1}^{(1)} + J_{2\alpha,2\beta}^{(1)}) + \frac{i}{2}(J_{2\alpha,2\beta-1}^{(1)} + J_{1,2\alpha-2\beta-1}^{(1)})
\]

(2.21)

together with

\[
J_{\alpha\beta} = \psi^*_\alpha(z)\psi^*_\beta(z), \quad J_{\alpha\beta} = \psi_\alpha(z)\psi_\beta(z)
\]

(2.22)

so that we see explicitly \( \widehat{\mathfrak{gl}}(N)_1 \subset \widehat{\mathfrak{so}}(n)_1 \). Note also that elements \( J_{\alpha\alpha}(z) = \hat{J}_\alpha(z) \) again form the Heisenberg algebra, and its zero modes \( J_{\alpha,0} \) correspond to the Cartan subalgebra of \( \mathfrak{so}(n) \).

As before, we define the W-algebra \( W(\mathfrak{so}(n)) \) as commutant of \( \mathfrak{so}(n) \subset \widehat{\mathfrak{so}}(n)_1 \). In contrast to the simply-laced cases we find this commutant for \( B_N \)-series not in completion of the \( U(\mathfrak{so}(2N+1)_1) \), but in the entire fermionic algebra. An inclusion of algebras \( \mathfrak{gl}(N) \subset \mathfrak{so}(2N) \), acting on the same space, leads to inverse inclusion

\[
W(\mathfrak{so}(2N)) \subset W(\mathfrak{gl}(N))
\]

(2.23)

Similarly to (2.9) one can present the generators of the \( W(\mathfrak{so}(n)) \)-algebra explicitly, using the real fermions

\[
U_k(z) = \frac{1}{2}D_z^{-k} \sum_{j=1}^{n} :\Psi_j(z)\Psi_j(z):, \quad V(z) = \prod_{j=1}^{n}\Psi_j(z)
\]

(2.24)

The last current is bosonic in \( D_N \) case and fermionic for \( B_N \). These expressions are obtained analogously to (2.9) with the help of invariant theory, the only important difference is that for \( SO(n) \) case there is also completely antisymmetric invariant tensor. We can rewrite these expressions using complex fermions (for the \( D_N \) case one should just put here \( \Psi(z) = 0 \) in the expressions for \( U \)-currents and \( \Psi(z) = 1 \) in the expressions for the \( V \)-current)

\[
U_k(z) = \frac{1}{2}D_z^{-k} \sum_{\alpha=1}^{N} (\psi^*_\alpha(z)\psi_\alpha(z) + \psi_\alpha(z)\psi^*_\alpha(z)) + \frac{1}{2}D_z^{-k}\Psi(z)\Psi(z)
\]

(2.25)

\[
V(z) = \prod_{\alpha=1}^{N}:\psi^*_\alpha(z)\psi_\alpha(z):\Psi(z)
\]

It is easy to see that odd generators vanish \( U_{2k+1} = 0 \), while even generators in \( D_N \) case coincide with those in \( W(\mathfrak{gl}(N)) \) algebra

\[
U_{2k}(z) = D_z^{2k-1} \sum_{\alpha=1}^{N} :\psi^*_\alpha(z)\psi_\alpha(z): + \frac{1}{2}D_z^{2k-1}\Psi(z)\Psi(z), \quad k = 1, 2, \ldots
\]

(2.26)
So finally we have the following sets of independent generators:

\[
\begin{align*}
U_1(z), U_2(z), \ldots, U_N(z) & \quad \text{for } W(\mathfrak{gl}(N)) \\
U_2(z), U_4(z), \ldots, U_{2N-2}(z), V(z) & \quad \text{for } W(\mathfrak{so}(2N)) \\
U_2(z), U_4(z), \ldots, U_{2N}(z), V(z) & \quad \text{for } W(\mathfrak{so}(2N+1))
\end{align*}
\] (2.27)

3 Twist-field representations from twisted fermions

3.1 Twisted representations and twist-fields

For any current algebra, generated by currents \(\{\Phi_I(z)\}\), the commutation relations follow from their local OPE’s

\[
\Phi_I(z)\Phi_J(w) = \sum_K \frac{(\Phi_I\Phi_J)_K(w)}{(z - w)^K}
\] (3.1)

However, to define the commutation relations, in addition to local OPE’s one should also know the boundary conditions for the currents: in radial quantization – the analytic behaviour of \(\Phi_I(z)\) around zero. Any vertex operator \(V_g(0)\), e.g. sitting at the origin, can create nontrivial monodromy for our currents:

\[
\Phi_I(e^{2\pi i}z) V_g(0) = \sum_j g_{IJ} \Phi_J(z) V_g(0)
\] (3.2)

for some linear automorphism of the current algebra.

Example Perhaps the simplest example of such nontrivial monodromy is the diagonal transformation of the fermionic fields

\[
\psi^*_\alpha(e^{2\pi i}z) = e^{2\pi i \theta_\alpha} \psi^*_\alpha(z), \quad \psi_\alpha(e^{2\pi i}z) = e^{-2\pi i \theta_\alpha} \psi_\alpha(z), \quad \alpha = 1, \ldots, N
\] (3.3)

which just shifts the mode expansion indices

\[
\psi^*_\alpha(z) = \sum_{p \in \mathbb{Z} + \frac{1}{2}} \frac{\psi^*_\alpha, p}{z^{p + \frac{1}{2} + \theta_\alpha}}, \quad \psi_\alpha(z) = \sum_{p \in \mathbb{Z} + \frac{1}{2}} \frac{\psi_\alpha, p}{z^{p + \frac{1}{2} + \theta_\alpha}}
\] (3.4)

Instead of the OPE (2.2) one gets therefore

\[
\psi^*_\alpha(z)\psi_\beta(w) \rightarrow z^{\theta_\alpha w - \theta_\beta} \psi^*_\alpha(z)\psi_\beta(w) = \frac{\delta_{\alpha\beta} z^{\theta_\alpha w - \theta_\beta}}{z - w} + z^{\theta_\alpha w - \theta_\beta} : \psi^*_\alpha(z)\psi_\beta(w) : =
\]

\[
= \frac{\delta_{\alpha\beta}}{z - w} + \frac{\theta_\alpha \delta_{\alpha\beta}}{w} : \psi^*_\alpha(w)\psi_\beta(w) : + \text{reg.}
\] (3.5)

which means that for the shifted fermions (3.4) one should use different normal ordering:

\[
(\psi^*_\alpha(z)\psi_\beta(z)) = \frac{\theta_\alpha \delta_{\alpha\beta}}{z} + : \psi^*_\alpha(z)\psi_\beta(z) :
\] (3.6)

\[\text{For nontrivial boundary conditions we assume presence of such field by default, when obvious – not indicating it explicitly.}\]
This implies that for the diagonal components \( \hat{\mathfrak{gl}}(N) \) algebra one has extra shift \( J_\alpha(z) \to J_\alpha(z) + \frac{\theta_\alpha}{z} \), while for the non-diagonal currents we obtain

\[
J_{\alpha\beta}(z) = \sum_{n \in \mathbb{Z}} J_{\alpha\beta,n} z^{n+1+\theta_\alpha-\theta_\beta}
\]  

(3.7)

so that the commutation relations for this “twisted” Kac-Moody algebra become

\[
[J_{\alpha\beta,n}, J_{\gamma\delta,m}] = (n - \theta_\alpha + \theta_\beta)\delta_{n+m,0}\delta_{\beta\gamma}\delta_{\alpha\delta} + \delta_{\beta\gamma}J_{\alpha\delta,m+n} - \delta_{\alpha\delta}J_{\beta\gamma,m+n}
\]  

(3.8)

We see that these commutation relations differ from the conventional ones only by the extra shift which can be hidden into the Cartan generators \( J_{\alpha\alpha,0} \). However, in the twisted case \( \hat{\mathfrak{gl}}(N) \) does not contain zero modes, and we cannot think about the W-algebra as about commutant of some \( \mathfrak{gl}(N) \). But nevertheless we define the currents

\[
U_k(z) = D^{k-1}_z \sum_{\alpha=1}^N (\psi^*_\alpha(z) \cdot \psi_\alpha(z))
\]  

(3.9)

One can still use two basic facts:

- since \( U_k(e^{2\pi i}z) = U_k(z) \), they are expanded in integer powers of \( z \) as before;
- they satisfy the same algebraic relations for all values of monodromies \( \{\theta_\alpha\} \), because the OPE’s of \( \psi_\alpha, \psi^*_\alpha \) (and so the OPE’s of \( U_k \)) do not depend on these monodromy parameters.

Consider now more general situation, when

\[
\psi^*_\alpha(e^{2\pi i}z) = \sum_{\beta=1}^N g_{\alpha\beta}\psi^*_\beta(z), \quad \psi_\alpha(e^{2\pi i}z) = \sum_{\beta=1}^N g^{-1}_{\beta\alpha}\psi_\beta(z)
\]  

(3.10)

i.e. unlike (3.3), the monodromy is no longer diagonal. It is clear that then the action on \( \hat{\mathfrak{gl}}(N) \) is

\[
J_{\alpha\beta}(z) \to g_{\alpha\alpha'}g^{-1}_{\beta\beta'}J_{\alpha'\beta'}(z)
\]  

(3.11)

The most general transformation we consider in the \( O(n) \) case mixes \( \psi \) and \( \psi^* \):

\[
\psi_\alpha(e^{2\pi i}z) = \sum_{\beta=-N}^N g_{\alpha\beta}\psi_\beta(z), \quad \alpha = -N, \ldots, N
\]  

(3.12)

where it is convenient to introduce conventions \( \psi^*_{-\alpha} = \psi_\alpha, \alpha > 0 \), and \( \psi_0 \) can be absent. Matrix \( g \) here should preserve the anticommutation relations.

Consider now a sequence of algebras

\[
\text{W algebra} \subset \text{Heisenberg algebra} \hat{\mathfrak{h}} \subset \text{KM-algebra} \subset \text{Fermions}.
\]

---

5This element should preserve the structure of the OPEs, so it should preserve symmetric form on fermions, and lies therefore in \( O(2N) \). Notice that it automatically implies that all even generators of the W-algebra \( \hat{U}_{2k}(w) \) are also preserved. To preserve odd generators \( \hat{U}_{2k+1}(z) \) one should have also \( g \in Sp(2N) \), but \( O(2N) \cap Sp(2N) = GL(N) \), so \( g \in GL(N) \).
Taking an element $g \in G$ we construct a twisted representation of the fermionic algebra $\psi, \psi^*$. Then, for $G = GL(N)$ or $G = SO(2N)$ one gets the KM algebra as invariant of the group $\Gamma$, acting on fermionic algebra. The group $\Gamma$ is $U(1)$ and $\mathbb{Z}/2\mathbb{Z}$ in two cases correspondingly. Therefore the twisted representations of KM algebra are labeled by pairs $(g, \text{representation of } \Gamma)$, in what follows we denote such pair by $\hat{g}$. We also denote by $\mathcal{H}_{\hat{g}}$ the corresponding representation of the KM algebra for $G = GL(N)$ or $G = SO(2N)$. For the $G = SO(2N + 1)$ case $\mathcal{H}_{\hat{g}}$ is a representation of the fermionic algebra itself. Explicit description of $\mathcal{H}_{\hat{g}}$ and calculation of its characters is given in Section [4] using bosonization.

However, to use bosonization one has to restrict the elements $g \in N_G(h) \subset G$ to the Cartan normalizer, and this will be the key object in our definition of the twist fields. In particular, bosonization means that we consider the space $\mathcal{H}_{\hat{g}}$ as a sum of twisted representation of the Heisenberg algebra $\hat{h}$. These representations depend not only on the elements $g \in N_G(h)$ but also on additional data: eigenvalues of the zero modes in $\hat{h}$. This extra, to be called $r$-charges below, data has discrete freedom, since the exponents of such eigenvalues are specified by $g$. We denote below the most refined data as $\tilde{g} = (g, r)$. Finally, we consider the twisted representations of Heisenberg as representations of the W-algebra, already untwisted since W-algebra generators are $G$-invariant.

**Definition 1** We call the vertex operator $\mathcal{V}_{\tilde{g}} = O_{\tilde{g}}$ a twist field when $g$ lies in the normalizer of Cartan $h \subset g$, i.e. $g \in N_G(h)$ iff

$$g h g^{-1} = h \quad (3.13)$$

Such elements also preserve the Heisenberg subalgebra $\hat{h} = \langle J_1(z), \ldots, J_{\text{rank } g}(z) \rangle \subset \hat{g}_1$

$$\hat{g} h g^{-1} = \hat{h} \quad (3.14)$$

If different elements $g_1, g_2 \in N_G(h)$ are conjugated in $G$: $g_1 = \Omega g_2 \Omega^{-1}$, then such conjugation identifies $g_1$ and $g_2$ twistings of the fermionic algebras. This conjugation also induces one-to-one correspondence between the set of $\hat{g}_1$ and the set of $\hat{g}_2$, and maps the twisted representation $\mathcal{H}_{\hat{g}_1}$ to $\mathcal{H}_{\hat{g}_2}$.

More formally, if we denote corresponding representations by $T_{\hat{g}_1}(\hat{g}_2): \hat{g}_2 \to \text{End} \mathcal{H}_{\hat{g}_1}$, and the action of $\Omega$ by $\Omega_{12}: \mathcal{H}_{\hat{g}_1} \to \mathcal{H}_{\hat{g}_2}$, then we have $\Omega_{12} T_{\hat{g}_1} (J(z)) \Omega_{12}^{-1} = T_{\hat{g}_2} (J(z)) \Omega$. Note, that twisted representations of KM algebra $\mathcal{H}_{\hat{g}_1}, \mathcal{H}_{\hat{g}_2}$ are not isomorphic due to appearance of conjugation by $\Omega$: the current $J(z)$ can have different monodromies in $\mathcal{H}_{\hat{g}_1}$ and $\mathcal{H}_{\hat{g}_2}$. But the corresponding representations of W-algebra become equivalent (up to external automorphism in case of $SO(2N)$), see details in sec. [4.6.3].

If $g_1 = \Omega g_2 \Omega^{-1}$, with $\Omega \in N_G(h)$, then the conjugation by $\Omega$ preserves $\hat{h}$. Therefore this conjugation induces the transformation of twisted representations $\hat{h}$ in $\mathcal{H}_{\hat{g}_1}$ into twisted representations of $\hat{h}$ in $\mathcal{H}_{\hat{g}_2}$, and induces one-to-one correspondence between the sets of $\hat{g}_1$ and $\hat{g}_2$. Hence we have an action of $N_G(h)$ on the set of $\hat{g}$.

Below we describe the structure of the Cartan normalizers $N_{GL(N)}(h)$ and $N_{O(n)}(h)$ and specify notations $\hat{g}$ and $\tilde{g}$ in these cases explicitly. We also describe the representatives of the all orbits in the set of $\hat{g}$ under the action of $N_G(h)$.

---

*One can compare this conjugation and additional data in $\hat{g}, \tilde{g}$ with the description of the representations of G-invariant part of vertex algebra in case of finite group $G$ in [21].*
3.2 Cartan normalizers

Structure of the Cartan normalizer for $\mathfrak{g}(N)$. Let us choose the Cartan subalgebra in a standard way $\mathfrak{h} \supset \text{diag}(x_1, \ldots, x_N)$, so conjugation \( \text{(3.13)} \) can only permute the eigenvalues. Therefore we conclude that

$$ g = s \cdot (\lambda_1, \ldots, \lambda_N) \in S_N \ltimes (\mathbb{C}^\times)^N = N_{\text{GL}(N)}(\mathfrak{h}) $$

(3.15)

or just $g$ is a quasipermutation.

Let us now find the conjugacy classes in this group. Any element of $N_{\text{GL}(N)}(\mathfrak{h})$ has the form $g = (c_1 \cdots c_k, (\lambda_1, \ldots, \lambda_N))$, where $c_i$ are the cyclic permutations – their only parameters are lengths $l_j = l(c_j)$. It is enough to consider just a single cycle of the length $l = l(c)$

$$ g = (c, (\lambda_1, \ldots, \lambda_l)) $$

(3.16)

since any $g$ can be decomposed into a product of such elements. Conjugation of this element by diagonal matrix is given by

$$ (1, (\mu_1, \ldots, \mu_l)) \cdot (c, (\lambda_1, \ldots, \lambda_l)) \cdot (1, (\mu_1, \ldots, \mu_l))^{-1} = (c, (\lambda_1, \lambda_2, \ldots, \lambda_l)) $$

(3.17)

Therefore one can always adjust \( \{\mu_i\} \) to replace all \( \{\lambda_i\} \) by the same number, e.g. to put \( \lambda_1 \mapsto \bar{\lambda} = \prod_{j=1}^{l} \lambda_j^{1/l} = e^{\frac{i\pi r}{l}} e^{2\pi i r}. \) These “averaged over a cycle” parameters have been called as $r$-charges in \( \text{(3.13)} \). Hence, all elements of $g \in N_{\text{GL}(N)}(\mathfrak{h})$ can be conjugated to the products over the cycles

$$ [g] \sim \prod_{j=1}^{K} [l_j, e^{i\frac{1-l_j}{l_j}} \bar{\lambda}_j] = \prod_{j=1}^{K} [l_j, e^{2\pi i r_j}] $$

(3.18)

Transformation \( [l, e^{2\pi i r}] \) acts like follows:

$$ \psi_{\alpha}^{*} \mapsto e^{i\frac{r}{l_j}} e^{2\pi i r} \psi_{\alpha+1}^{*}, \quad \psi_{\alpha} \mapsto e^{i\frac{r}{l_j}} e^{-2\pi i r} \psi_{\alpha+1}, $$

(3.19)

where $\psi_{\alpha+l} = \psi_{\alpha}$, and we have included extra factor $e^{i\frac{r}{l_j}}$ into the definition of transformation in order to have simple formula

$$ \det[l, e^{2\pi i r}] = e^{2\pi i r l} $$

(3.20)

and to simplify the identification between $r$ and $U(1)$ charge in Appendix \( \text{(3.3)} \).

In this case $\hat{g}$ is just a pair \( (g, \text{tr} \log g) \), the value of \( \text{tr} \log g \) is defined up to $2\pi \mathbb{Z}$, and this freedom corresponds to the representation of $\Gamma = U(1)$ mentioned above. Element $\hat{g}$ contains information about all $r$-charges $\bar{g} = (g, r)$, for given $g$ the $r$-charge $r_j$ is defined by $g$ up to the shift by $\frac{1}{l_j} \mathbb{Z}$. If $\hat{g}_1$ and $\hat{g}_2$ correspond to the same $\hat{g}$, then the corresponding $r$-charges differ by the shift in certain lattice, see character formula \( \text{(4.4)} \) in Sect. \( 4 \).

Structure of $N_{O(n)}(\mathfrak{h})$. Using complexification of fermions \( \text{(2.20)} \) we rewrite the quadratic form $ds^2 = \sum_{i=1}^{n} d\Psi_i^2$ as $ds^2 = \sum_{\alpha=1}^{N} d\psi_{\alpha}^* d\psi_{\alpha} + d\Psi^2 = \sum_{\alpha=1}^{N} d\psi_{-\alpha} d\psi_{\alpha} + d\Psi^2$ (the last term is present only for the $B_N$-series). In this basis the $\mathfrak{so}(n)$ algebra (the algebra, preserving this form)
becomes just the algebra of matrices, which are antisymmetric under the reflection w.r.t. the anti-diagonal. In particular, the Cartan elements are given by

\[ h \ni \text{diag}(x_1, \ldots, x_N, 0, -x_N, \ldots, -x_1) \quad (3.21) \]

for \( B_N \)-series (and for the \( D_N \)-series 0 in the middle just should be removed). The action of an element from \( N_{O(n)}(h) \) should preserve the chosen quadratic form, and, when acting on the diagonal matrix \((3.21)\), it can either permute some eigenvalues, also doing it simultaneously in the both blocks, or interchange \( x_\alpha \) with \(-x_\alpha\) (the same as to change the sign of \( x_\alpha \)). It is defined in this way up to a subgroup of diagonal matrices themselves. In other words

\[
N_{O(2N)}(h) = S_N \ltimes (\mathbb{Z}/2\mathbb{Z})^N \ltimes (\mathbb{C}^\times)^N \\
N_{O(2N+1)}(h) = N_{O(2N)}(h) \times \mathbb{Z}/2\mathbb{Z} \quad (3.22)
\]

where the last factor \( \mathbb{Z}/2\mathbb{Z} \) comes from changing sign of the extra fermion \( \Psi \). This triple \((s, \vec{\sigma}, \vec{\lambda}) \in N_{O(n)}(h)\), with \( s \in S_N \), \( \sigma_\alpha \in \mathbb{Z}/2\mathbb{Z} \) and \( \lambda_\alpha \in \mathbb{C}^\times \), is embedded into \( O(n) \) as follows

\[
S_N : \{ \{ \alpha \mapsto s(\alpha) \}, 1, 1 \} = \{ \psi_\alpha \mapsto \psi_{s(\alpha)} ; \psi^*_\alpha \mapsto \psi^*_{s(\alpha)} \}
\]

\[
(\mathbb{Z}/2\mathbb{Z})^N : (1, \vec{\sigma}, 1) = \{ \psi_\alpha \mapsto \psi_{\sigma_\alpha} \}
\]

\[
(\mathbb{C}^\times)^N : (1, 1, \vec{\lambda}) = \{ \psi_\alpha \mapsto \lambda_\alpha \psi_\alpha ; \psi^*_\alpha \mapsto \lambda^{-1}_\alpha \psi^*_\alpha \}
\]

and in these formulas \( \psi_{-\alpha} = \psi^*_\alpha \) and \( \psi^*_{-\alpha} = \psi_\alpha \) is again implied. The structure of the actions in the semidirect product has the obvious from:

\[
\vec{\sigma} : \lambda_\alpha \mapsto \lambda^\sigma_\alpha, \quad s : (\sigma_\alpha, \lambda_\alpha) \mapsto (\sigma_{s(\alpha)}, \lambda_{s(\alpha)}) \quad (3.24)
\]

Notice that normalizer of Cartan in \( SO(n) \)

\[
N_{SO(n)}(h) = SO(n) \cap N_{O(n)}(h) \quad (3.25)
\]

is distinguished by condition that \( \prod_{\alpha=1}^N \sigma_\alpha = 1 \), and the Weyl group is given as the factor of this normalizer by the Cartan torus

\[
W(\mathfrak{so}(n)) = N_{SO(n)}(h)/H \quad (3.26)
\]

Consider now the conjugacy classes in \( N_{O(n)}(h) \). First, conjugating an arbitrary element \((s, \vec{\sigma}, \vec{\lambda})\) by permutations, we again reduce the problem to the case when \( s = c \) is just a single cycle. Then one can further conjugate this element by \((\mathbb{Z}/2\mathbb{Z})^N:\)

\[
(1, \vec{\epsilon}, 1) \cdot (c, \vec{\sigma}, 1) \cdot (1, \vec{\epsilon}, 1)^{-1} \mapsto (c, (\sigma_1 \cdot \epsilon_1 \epsilon_2, \sigma_2 \epsilon_2 \epsilon_3, \ldots, \sigma_N \cdot \epsilon_1 \epsilon_N), 1) \quad (3.27)
\]

and solving equations for \( \{ \epsilon_\alpha \} \), remove all \( \sigma_\alpha = -1 \), except for, maybe, one. Hence:

- For \( \sigma = (1, \ldots, 1) \) the situation is the same as in \( \mathfrak{gl}(N) \) case: we can transform \( \vec{\lambda} \) to \((\lambda, \ldots, \lambda)\). These conjugacy classes are therefore the same (but denoted by \([l, \lambda]_+\)):

\[
(c, 1, \vec{\lambda}) \sim [l(c), e^{i\pi \frac{1}{l(c)}} \prod_1^N \lambda^{1/l(c)}]_+ \quad (3.28)
\]
• For, say, \( \sigma = (-1, 1, \ldots, 1) \) let us conjugate this element by \((1, 1, \bar{\mu})\):

\[
(1, 1, \bar{\mu})(c, (-1, 1, \ldots, 1), \bar{\xi})(1, 1, \bar{\mu})^{-1} = (c, (-1, 1, \ldots, 1), \bar{\xi}')
\]

\[
\bar{\xi}' = (\lambda_1\mu_1\mu_2^{-1}, \lambda_2\mu_2\mu_3^{-1}, \ldots, \lambda_{l-1}\mu_{l-1}\mu_l^{-1}, \lambda_l\mu_1)
\]

(3.29)

In contrast to the previous case, here one can put all \( \lambda_i' = 1 \), since one can put first \( \mu_2^2 = \prod_i \lambda_i^{-1} \), and then solve \( N - 1 \) equations \( \mu_{i+1} = \lambda_i\mu_i \) not being restricted by any boundary conditions. It means that

\[
(c, (-1, 1, \ldots, 1), \bar{\xi}) \sim [l(c)]
\]

(3.30)

Therefore we can formulate:

**Lemma 1** One gets for the conjugacy classes

\[
N_{O(2N)}(h) : g \sim \prod_{j=1}^{K}[l_j, \lambda_j]_+ \cdot \prod_{j=1}^{K'}[l_j]_-
\]

\[
N_{O(2N+1)}(h) : g \sim [e] \cdot \prod_{j=1}^{K}[l_j, \lambda_j]_+ \cdot \prod_{j=1}^{K'}[l_j]_-
\]

(3.31)

and we are now ready to describe the twist fields in detail.

As in the \( GL(N) \) case, to be precise one should add explicit values of the \( r \)-charges, i.e. to consider pairs \( \tilde{g} = (g, r) \). Moreover, for even \( n = 2N \) it is also useful to introduce \( \tilde{g} = (g, \tilde{r}) \), where \( \tilde{r} \in \mathbb{R}^K/Q_{DK} \) is defined up to addition of the vectors from \( D_K \) root lattice: \( r \sim \tilde{r} \mod Q_{DK} \) (for odd \( n \) we just take \( \tilde{g} = g \)).

### 3.3 Twist fields and bosonization for \( \mathfrak{gl}(N) \)

Take an element (3.18), whose action on fermions (in the fundamental and antifundamental representations), say for a single cycle, is

\[
g : (\psi_\alpha^*(z), \psi_\alpha(z)) \mapsto (e^{i\pi r_\alpha l} e^{2\pi i r} \psi_\alpha^*(z), e^{i\pi r_\alpha l} e^{-2\pi i r} \psi_{\alpha+1}(z)), \quad \text{mod } l
\]

(3.32)

while the corresponding (adjoint) action on the Cartan is just

\[
g_{\text{Adj}} : J_\alpha(z) \mapsto J_{\alpha+1}(z), \quad \text{mod } l
\]

(3.33)

Such formulas have simple geometric interpretation [25]: there is the branched cover in the vicinity of the point \( z = 0 \) given by \( \xi^l = z \), so that all these (fermionic and bosonic) fields are actually defined on different sheets \( \xi^{(\alpha)} = z^{1/l} e^{2\pi i \alpha/l} \) of the cover:

\[
\psi_\alpha^*(z) \sqrt{dz} = \tilde{\psi}_\alpha^*(\xi^{(\alpha)}) \sqrt{d\xi^{(\alpha)}}, \quad \psi_\alpha(z) \sqrt{dz} = \tilde{\psi}_\alpha(\xi^{(\alpha)}) \sqrt{d\xi^{(\alpha)}}
\]

\[
J_\alpha(z) dz = J(\xi^{(\alpha)}) dz = \tilde{J}(\xi^{(\alpha)}) d\xi^{(\alpha)}
\]

(3.34)

\(^7\)Actually there are only two elements \( \tilde{g} \) that correspond to given \( g \). This is because \( r \) is defined by \( g \) up to \( \mod Z^K \) (we have to take logarithms), and \( |Z^K/Q_{DK}| = 2 \). Explicit action of the lattices is given by \( l_i r_i \mapsto l_i r_i + n_i \), where for \( Q_{DK} \) we need \( \sum n_i \in 2Z \).
Using these formulas one can write down expansions for the fields on the cover, whose OPE's would be locally given by

\[ \tilde{\psi}^*(\xi)\tilde{\psi}(\xi') = \frac{1}{\xi - \xi'} + \text{reg.,} \quad \tilde{J}(\xi)\tilde{J}(\xi') = \frac{1}{(\xi - \xi')^2} + \text{reg.} \] (3.35)

Now one write for the mode expansion of fermions, which are already twisted on the covering curve by \( e^{2\pi i r} \):

\[
\psi(z) = \sqrt{\frac{d\xi}{dz}} \tilde{\psi}(\xi) = z^{\frac{1}{l} - \frac{1}{2}} \sum_{p \in \mathbb{Z} + \frac{1}{2}} \frac{\psi_p}{\xi^{p + \frac{1}{2} + \sigma}} = \frac{1}{\sqrt{l}} \sum_{p \in \mathbb{Z} + \frac{1}{2}} \frac{\psi_p}{z^{\frac{1}{2} + (p + \sigma)}}
\]

\[
\psi^*(z) = \sqrt{\frac{d\xi}{dz}} \tilde{\psi}^*(\xi) = z^{\frac{1}{l} - \frac{1}{2}} \sum_{p \in \mathbb{Z} + \frac{1}{2}} \frac{\psi_p^*}{\xi^{p + \frac{1}{2} - \sigma}} = \frac{1}{\sqrt{l}} \sum_{p \in \mathbb{Z} + \frac{1}{2}} \frac{\psi_p^*}{z^{\frac{1}{2} + (p - \sigma)}}
\] (3.36)

Due to (3.3), one should have \( \psi^*(e^{2\pi i l} z) = (-1)^{l-1} e^{2\pi i r} \psi^*(z) \) and \( \psi(e^{2\pi i l} z) = (-1)^{l-1} e^{-2\pi i r} \psi(z) \), therefore one can take \( \sigma = lr \), so that:

\[
\psi(z) = \frac{1}{\sqrt{l}} \sum_{p \in \mathbb{Z} + \frac{1}{2}} \frac{\psi_p}{z^{\frac{1}{l} (p + \frac{1}{2}) + r + \frac{l}{2l}}} \quad \psi^*(z) = \frac{1}{\sqrt{l}} \sum_{p \in \mathbb{Z} + \frac{1}{2}} \frac{\psi_p^*}{z^{\frac{1}{l} (p + \frac{1}{2}) + r - \frac{l}{2l}}}
\]

or the mode expansion is shifted by the \( r \)-charges, corresponding to given cycles.

The same procedure gives for the twisted bosons

\[
J(z) = \frac{1}{l} z^{\frac{1}{l} - 1} \tilde{J}(\xi) = \frac{1}{l} z^{\frac{1}{l} - 1} \sum_{n \in \mathbb{Z}} J_{n/l} = \frac{1}{l} z^{\frac{1}{l} - 1} \sum_{n \in \mathbb{Z}} \frac{J_{n/l}}{z^{\frac{1}{l}(n+1)}} = \frac{1}{l} \sum_{n \in \mathbb{Z}} J_{n/l} z^{-\frac{1}{l}(n+1)}
\] (3.38)

with the commutation relations between their modes being

\[
[J_{n/l}, J_{m/l}] = n\delta_{n+m,0} \quad n, m \in \mathbb{Z}
\] (3.39)

These twisted bosons provide one of the convenient languages for the twist field representations. The other one is provided by bosonization of the constituent fermions with the fixed fractional parts of the power expansions in (3.37)

\[
\psi(z) = \frac{1}{\sqrt{l}} \sum_{a \in \mathbb{Z}/lz} \psi(a)(z), \quad \psi(a)(e^{2\pi i z}) = e^{-i\pi \frac{l}{4l} - 2\pi i r - 2\pi i a} \psi(a)(z)
\]

\[
\psi^*(z) = \frac{1}{\sqrt{l}} \sum_{a \in \mathbb{Z}/lz} \psi^*_a(z), \quad \psi^*_a(e^{2\pi i z}) = e^{i\pi \frac{l}{4l} + 2\pi i r + 2\pi i a} \psi^*_a(z)
\] (3.40)

The corresponding bosons (see (B.45) in Appendix)

\[
I_{(a)}(z) = (\psi^*_a(z)\psi(a)(z)) = \sum_{n \in \mathbb{Z}} \frac{I_{(a)}^n}{z^{n+1}} + \frac{1}{z} \left( r + \frac{a}{l} + \frac{1 - l}{2l} \right)
\] (3.41)

always have integer mode expansion.

14
3.4 Twist fields and bosonization for $\mathfrak{so}(n)$

Let us mention first, that there is a difference between the groups $N_{O(n)}(\mathfrak{h})$ and $N_{SO(n)}(\mathfrak{h})$, since the action of the first one can also map $V(z) \mapsto -V(z)$, so that one of the generators of the W-algebra $V(e^{2\pi i z}) = -V(z)$ becomes a Ramond field, and we allow this extra minus sign below.

In addition to the conjugacy classes $[l, \lambda]_+$, similar to those of $\mathfrak{gl}(N)$, we now also have to study $[l]_-$'s. First one has to identify the action of $N_{O(n)}(\mathfrak{h})$ on the fermions, where just by definition:

$$\sigma_\alpha = -1: \ (1, \bar{\sigma}, 1): \psi_\alpha \mapsto \psi_\alpha^*$$  \hspace{1cm} (3.42)

This means that the element of our interest is the complete cycle

$$[l]_-: \psi_1 \mapsto \psi_2 \mapsto \ldots \mapsto \psi_l \mapsto \psi_1^* \mapsto \ldots \mapsto \psi_l^* \mapsto \psi_1$$  \hspace{1cm} (3.43)

Therefore $2N$ complex fermions can be realized as a pushforward of a single real fermion $\eta(\xi)$, living on a $2l$-sheeted branched cover

$$\psi_\alpha(z)\sqrt{dz} = \eta(\xi^{(\alpha)})\sqrt{d\xi}$$  \hspace{1cm} (3.44)

$$\psi_\alpha^*(z)\sqrt{dz} = \eta(\xi^{l+\alpha})\sqrt{d\xi}$$

Here the branched cover $z = \xi^{2l}$ can be realized as a sequence of two covers $\pi_2: \xi \mapsto \zeta = \xi^2$ and $\pi_l: \zeta \mapsto \zeta^l = z$, and it leads to more tricky global construction of the exact conformal blocks, see sect. below.

An important fact is that there is an element $\sigma \in (N_{O(n)}(\mathfrak{h})/H)$ in the center of this group

$$\sigma = (1, (-1, -1, \ldots, -1))$$  \hspace{1cm} (3.45)

which generates the global automorphism of the cover of order two, which is continued to the global automorphism of algebraic curve during the consideration of exact conformal blocks in sect. It acts locally by $\xi \mapsto -\xi$. Using this element one can write the OPE of $\eta(\xi)$ in the form:

$$\eta(\xi)\eta(\sigma(\xi')) = \frac{1}{\xi - \xi'} + \text{reg.} \hspace{1cm} (3.46)$$

Now the analytic structure of this field can be obtained

$$\psi(z) = \sqrt{\frac{d\xi}{dz}} \eta(\xi) = \frac{z^{\frac{n}{2}}}{\sqrt{2l}} \sum_{p \in \mathbb{Z} + \frac{1}{2}} \frac{\eta_{n+\frac{1}{2}}}{z^{\frac{1}{2}(p+\frac{1}{2}+\sigma)}} = \frac{1}{\sqrt{2l}} \sum_{p \in \mathbb{Z} + \frac{1}{2}} \frac{\eta_{n+\frac{1}{2}}}{z^{\frac{1}{2}(p+\frac{1}{2}+\sigma)}}$$  \hspace{1cm} (3.47)

$$\psi^*(z) = \psi(e^{2\pi i z})$$

In order to ensure right monodromies (3.43) for $\psi, \psi^*$ one should get powers $\frac{1}{2l} \mathbb{Z}$ in the r.h.s., which means that $\sigma \sim l - \frac{1}{2} \sim \frac{1}{2}$, and $\eta(\xi)$ turns to be a Ramond fermion with the extra ramification

$$\eta(\xi) = \sum_{n \in \mathbb{Z}} \frac{\eta_n}{\xi^{n+\frac{1}{2}}}, \quad \psi(z) = \frac{1}{\sqrt{2l}} \sum_{n \in \mathbb{Z}} \frac{\eta_n}{z^{\frac{n}{2}+\frac{1}{4}}}, \quad \psi^*(z) = \frac{(-)^l}{\sqrt{2l}} \sum_{n \in \mathbb{Z}} \frac{(-)^n \eta_n}{z^{\frac{n}{2}+\frac{1}{4}}}$$  \hspace{1cm} (3.48)

Note that in case of $n = 2N$ the action of $N_{SO(2N)}(\mathfrak{h})$ on $\mathfrak{h}$ is given by Weyl group action, but additional element from $N_{O(2N)}(\mathfrak{h})$ gives external (diagram) automorphism. Corresponding twisted representations could be viewed as a representation of twisted affine Lie algebra $D_N^{(2)}$. 

---

8Note that in case of $n = 2N$ the action of $N_{SO(2N)}(\mathfrak{h})$ on $\mathfrak{h}$ is given by Weyl group action, but additional element from $N_{O(2N)}(\mathfrak{h})$ gives external (diagram) automorphism. Corresponding twisted representations could be viewed as a representation of twisted affine Lie algebra $D_N^{(2)}$. 

---

15
Let us now construct (a twisted!) boson from this fermion by

$$J(z) = (\psi^*(z)\psi(z)) = (\psi(e^{2\pi i z})\psi(z))$$  \hspace{1cm} (3.49)

This boson behaves like follows under the action of twist field:

$$J_1 \mapsto J_2 \mapsto \ldots \mapsto J_l \mapsto -J_1 \mapsto \ldots \mapsto -J_l$$  \hspace{1cm} (3.50)

To realize this situation we may take the Ramond boson on the cover in variable $\zeta$:

$$J(z) = \frac{d\zeta}{dz} \sum_{r \in \mathbb{Z}^+} \frac{J_{r/l}}{z^{r+1}} = \sum_{n \in \mathbb{Z}} \eta_n z^{n^2} = \sigma_1 \sqrt{2} e^{i\phi_-(z)} e^{i\phi_+(z)}$$  \hspace{1cm} (3.53)

with the Pauli matrix $\sigma_1 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$, and it is discussed in detail in Appendix (B.1).

### 4 Characters for the twisted modules

Now we turn directly to the computation of characters, using bosonization rules. In order to do this one has to apply the following heuristic “master formula” for the trace

$$\chi_{\hat{g}}(q) = \text{tr}_{\mathcal{H}_{\hat{g}}} q^L \llap{=}_m \frac{\chi_{ZM}(q)}{\prod_k \prod_{n=1}^{\infty} (1 - q^{\theta_{\lambda_0, k}(g) + n})}$$  \hspace{1cm} (4.1)

over the space $\mathcal{H}_{\hat{g}}$, which is the minimal space closed under the action of both W-algebra and twisted Kac-Moody algebra. For simply-laced cases, $\mathfrak{gl}(N)$ and $\mathfrak{so}(2N)$, $\mathcal{H}_{\hat{g}}$ is the module of corresponding Kac-Moody algebra, whereas in the $\mathfrak{so}(2N+1)$ case it should be entire fermionic Fock module due to presence of the fermionic W-current. Explicit descriptions of $\mathcal{H}_{\hat{g}}$ are the following: for $\mathfrak{gl}(N)$ it is the subspace with fixed total fermionic charge, for $\mathfrak{so}(2N)$ it is the subspace with fixed parity of total fermionic charge, and for $\mathfrak{so}(2N+1)$ it is entire space.

Notice that this representation depends on $\hat{g}$ – not just $g$, and also it contains all representations of W-algebra with different $\hat{g}$ corresponding to the same $g$.

Denominator of (4.1) collects the contributions from the Fock descendants of twisted bosons (parameters $\theta_{\lambda_0, k}(g)$ are the eigenvalues of adjoint action of $g$ on the Cartan subalgebra), and the numerator – contribution of the zero modes. This formula is heuristic, moreover, in some important cases we also get contribution from extra fermion, sometimes it is more informative to consider super-characters etc. Below we prove the following

**Theorem 1** The characters of twisted representations are given by the formulas (4.4), (4.7), (4.10), (4.17), (4.19).
4.1 \( \mathfrak{gl}(N) \) twist fields

To be definite, let us fix an element \( g = \prod_{j=1}^{K} [l_j, e^{2\pi i r_j}] \) from \((3.24)\) which, according to \((3.32)\), performs the permutation of fermions with simultaneous multiplication by \( e^{\pm 2\pi i (r_j + l_j - 1)} \).

In this setting \( N \) fermions can be bosonized in terms of \( K \) twisted bosons (see details in Appendix \( \text{B.3} \), and here we just present the final formulas

\[
\begin{align*}
\psi^*_\alpha(z) &= \frac{1}{\sqrt{l}} e^{i\phi_-(e^{2\pi i a} z)} e^{\phi_+(e^{2\pi i a} z)} e^{Q_j(e^{2\pi i a} z) - \frac{1}{l} j_0^{(j)} (-1)^{k<j} j_0^{(k)}} \\
\psi_\alpha(z) &= \frac{1}{\sqrt{l}} e^{-i\phi_-(e^{2\pi i a} z)} e^{-\phi_+(e^{2\pi i a} z)} e^{-Q_j(e^{2\pi i a} z) - \frac{1}{l} j_0^{(j)} (-1)^{k<j} j_0^{(k)}}
\end{align*}
\]

(4.2)

for \( \alpha \in \mathbb{Z}/l_j \mathbb{Z} \), labeling the fields within \([l_j]\)-cycle. For the conformal dimension one gets therefore (see \((3.39)\), and computation by alternative methods in \((5.15)\), \((6.30)\))

\[
L_0 = \sum_{j=1}^{K} \frac{l_j^2 - 1}{24l_j} + \sum_{j=1}^{K} \frac{1}{2l_i} (j_0^{(j)})^2 + \ldots
\]

(4.3)

and since we are computing character of the space, obtained by the action of \( \mathfrak{gl}(N)_1 \), we have to take into account all vacua arising after the action of the shift operators \( e^{Q_j - Q_j'} \), i.e. labeled by \( A_{K-1} \) root lattice. Hence, the character \((4.1)\) for this case is given by

\[
\chi_g(q) = \sum_{n_1, \ldots, n_K=0}^{\infty} \frac{1}{q_1^{r_1} \cdots q_K^{r_K}} \prod_{j=1}^{K} \prod_{k=1}^{\infty} (1 - q^{k/l_j})
\]

(4.4)

In this formula the numerator collects contributions from the highest vectors \( \chi_{ZM} \) (they differ by the value of zero modes \( j_0^{(j)} \) of the Heisenberg algebras with generators \( J_{n/l_j}^{(j)} \), whereas the denominator contains the contributions from the descendants.

4.2 \( \mathfrak{so}(2N) \) twist fields, \( K' = 0 \)

Consider now the twist fields \((3.31)\) for \( g \in \mathfrak{N}_{O(2N)}(\mathfrak{h}) \), and take first \( K' = 0 \), so our twist has no minus-cycles

\[
g = \prod_{j=1}^{K} [l_j, e^{2\pi i r_j}]_+
\]

(4.5)

The only difference from the previous situation with the \( \mathfrak{gl}(N) \) case is that now one also have extra currents \( J_{\alpha\beta} = \psi^*_\alpha(z) \psi^*_\beta(z) \) and \( J_{\alpha\beta} = \psi_\alpha(z) \psi_\beta(z) \). It means that due to bosonization \((3.45)\), \((4.2)\) possible charge’s shifts now include \( e^{\pm(Q_0 - Q_0')} \), so the full lattice of the zero-mode charges (one zero mode for each cycle \([l_i, e^{2\pi i r_i}]_+\)) contains all points with

\[
\sum_{i=1}^{K} n_i \in 2\mathbb{Z}, \quad \{n_i\} \in \mathbb{Z}^K
\]

(4.6)
or is just the root lattice $Q_{DK}$. After corresponding modification of numerator and the same contribution of the twisted Heisenberg algebra to denominator, the formula for the character in this case acquires the form

$$
\chi_{\dot{g}}(q) = q^{\frac{\Delta_0}{g}} \prod_{j=1}^{K} \prod_{n=1}^{\infty} \frac{1}{1 - q^{n/l_j}} 
$$

(4.7)

### 4.3 $\mathfrak{so}(2N)$ twist fields, $K' > 0$

Take

$$
g = \prod_{j=1}^{K} [l_j, e^{2\pi i r_j}] + \prod_{j=1}^{K'} [l'_j] - \prod_{i=1}^{K} \frac{1}{2} l_j \sum_{k=1}^{K} \frac{1}{2} (n_j + l_j r_j)^2 \prod_{i=1}^{K} \prod_{k=1}^{\infty} (1 - q^{k/l_j}) 
$$

(4.8)

Now we have extra cycles of type $[l'_i]_-$, so we have extra $\eta$-fermions that have to be bosonized in a different way (B.18):

$$
\eta_i(z) = \frac{z^{-\frac{1}{2}}} {2 \sqrt{l}} e^{i\phi_-(z \frac{1}{\sqrt{l}})} e^{i\phi_+(z \frac{1}{\sqrt{l}})} (-1)^{\sum_{k} j_{i}^{(k)} \gamma_i} 
$$

(4.9)

where $\{\gamma_i, \gamma_j\} = 2\delta_{ij}$ are gamma-matrices (or generators of the Clifford algebra $\mathcal{Cl}_{K'}(\mathbb{C})$) in the smallest possible representation, which make different fermions anticommuting. Due to presence of $K'$ cycles of type $[l'_i]_-$, the zero-mode $\chi_{ZM}(q)$ generating operators include now $\gamma_j e^{Q(i)}$, which perform integer shifts of $i$-th bosonic zero mode together with inessential action on fermionic vacua – now we do not have to imply that the number of shifts by $e^{Q(i)}$ should be even. Hence, instead of $D_K$-lattice from (4.7) the numerator includes now summation over the root lattice $Q_{BK}$, i.e.

$$
\chi_{\dot{g}}(q) = q^{\Delta_0} \prod_{i=1}^{K'} \prod_{k=1}^{\infty} \frac{1}{1 - q^{k/l_i}} \prod_{i=1}^{K} \prod_{k=0}^{\infty} \frac{1}{1 - q^{(k+\frac{1}{2})/l'_i}} 
$$

(4.10)

where factor $2^{[K'+1]-1}$ corresponds to the dimension of the smallest representation of $\mathfrak{so}(K')$, generated by $\gamma_i \gamma_j$. Another simple factor $q^{\Delta_0}$ contains the minimal conformal dimension (without contribution of the “$r$-charges”)

$$
\Delta_0 = \sum_{i=1}^{K} \frac{l_i^2 - 1}{24l_i} + \sum_{i=1}^{K'} \frac{2l'_i^2 + 1}{48l'_i} 
$$

(4.11)

which will be computed below in (5.18), (6.30). Numerator of (4.10) contains $K$ contributions from twisted bosons corresponding to plus-cycles, and $K'$ contributions from twisted Ramond bosons corresponding to minus-cycles.
4.4 $\mathfrak{so}(2N+1)$ twist fields

The W-algebra $W(\mathfrak{so}(2N+1))$ contains fermionic operator $V(z) = \Psi_1(z) \ldots \Psi_{2N+1}(z)$, which cannot be expressed in terms of generators of $\mathfrak{so}(2N+1)_1$ since latter are all even in fermions. It means that to construct a module of the $W$-algebra one should use entire fermionic algebra. Taking into account the fermionic nature of this $W$-algebra one can consider $\mathbb{Z}/2\mathbb{Z}$ graded modules and define two different characters

$$
\chi^+(q) = \text{tr} q^{L_0}, \quad \chi^-(q) = \text{tr} (-1)^F q^{L_0}
$$

(4.12)

where $F$ is the fermionic number:

$$
(-1)^F U_k(z) = U_k(z)(-1)^F, \quad (-1)^F V(z) = -V(z)(-1)^F
$$

(4.13)

One of the characters vanishes $\chi^-(q) = 0$ if at least one fermionic zero mode exists, since each state gets partner with opposite fermionic parity. Such fermionic zero modes are always present for the Ramond fermions and $\eta$-fermions, so the only case with non-trivial $\chi^-(q)$ corresponds to:

$$
g = [1] \prod_{i=1}^K [l_i, e^{2\pi i r_i}]_+
$$

(4.14)

In this case our computation works as follows: take bosonization for the $[l]_+$-cycles in terms of $K$ twisted bosons (B.45), (4.12), then the fermionic operators produce the zero-mode shifts $e^{\pm Q(i)}$ with the fermionic number $F = F^b + F^f = 1$, and the Heisenberg generators $J_{n/l_i}^{(i)}$ with the fermionic number $F = F^b = 0$. Moreover, we also have an extra “true” fermion $\Psi(z)$ with $F = F^f = 1$. Therefore the total trace can be computed, separating bosons and fermions, as

$$
\chi^-(q) = \text{tr} q^{L_0} (-1)^F = \text{tr} q^{L^b_0} (-1)^{F^b} \cdot \text{tr} q^{L^f_0} (-1)^{F^f}
$$

(4.15)

where the traces over bosonic and fermionic spaces are given by

$$
\text{tr} q^{L^b_0} (-1)^{F^b} = \sum_{n_1, \ldots, n_K \in \mathbb{Z}} \prod_{i=1}^K \left( \frac{1}{2} (n_i + l_i r_i)^2 \right) \prod_{i=1}^K (1 - q^{n_i l_i})
$$

(4.16)

$$
\text{tr} q^{L^f_0} (-1)^{F^f} = \prod_{n=0}^\infty (1 - q^{n+\frac{1}{2}})
$$

Hence, the final answer for this character is given by

$$
\chi_g^-(q) = q^{\Delta^b} \left( \sum_{\vec{n} \in Q_{D_K}} \prod_{i=1}^K \frac{1}{2} (n_i + l_i r_i)^2 \right) \left( \prod_{\vec{n} \in Q_{D'_K}} \prod_{i=1}^K \frac{1}{2} (n_i + l_i r_i)^2 \right) \prod_{k=0}^\infty (1 - q^{k+\frac{1}{2}})
$$

(4.17)

where $D$- and $D'$-lattices are defined in (A.1).
Let us now turn to the computation of $\chi^+(q)$. Choose an element from $N_{O(2N+1)}(h)$

$$g = [(-1)^{a+1}] \prod_{i=1}^{K} [l_i e^{2\pi ir_i}]_+ \prod_{i=1}^{K'} [l'_i]_-$$

(4.18)

where $a = 0, 1$. The bosonized fermions $e^{ir_i(z)}$ contain elements $e^{Q^{(i)}}$ generating the $B_K$ root lattice, which together with contribution of the fermionic and Heisenberg modes finally give

$$\chi_\hat{g}^+(q) = q^{\Delta_0} \prod_{i=1}^{K} \prod_{k=1}^{\infty} (1 - q^{k/l_i}) \prod_{i=1}^{K'} \prod_{k=0}^{\infty} (1 - q^{k+\frac{1}{2}/l'_i})$$

(4.19)

where

$$\Delta_0 = \frac{\delta_{a,0}}{16} + \sum_{i=1}^{K} \frac{l_i^2 - 1}{24l_i} + \sum_{i=1}^{K'} \frac{2l'_i^2 + 1}{48l'_i}$$

(4.20)

Here the only new part, comparing to the $D_N$-case, is extra factor

$$\chi_f(q) = q^{\frac{\delta_{a,0}}{16}} \prod_{k=0}^{\infty} (1 + q^{\frac{a}{2}+k})$$

(4.21)

corresponding to $(R$ or $NS)$ fermionic contribution.

### 4.5 Character identities

In sect. 3 we have classified the twist fields by conjugacy classes in $N_G(h)$ (more precisely, by the orbits of $N_G(h)$ on the set of $\hat{g}$). However, it is possible that two different elements $g_1, g_2 \in N_G(h)$ in the normalizer of Cartan are nevertheless conjugated in $G$: $g_1 = \Omega g_2 \Omega^{-1}$. As was explained in sec. 3.1 conjugation by $\Omega$ maps twisted representation $\mathcal{H}_{g_1}$ to $\mathcal{H}_{g_2}$. The explicit formula is $\Omega_{12} T_{g_1}(J(z)) \Omega_{12}^{-1} = T_{g_2}(J(z)\Omega)$. Since $\psi^{(i)}(z)^\Omega = \Omega_{\alpha\beta} \psi^{(i)}(z), \psi^{(i)}(z)^\Omega = \Omega_{\alpha\beta} \psi^{(i)}(z)$, grading operator is invariant $L_0^\Omega = L_0$, and we have

**Theorem 2** If $\hat{g}_1 \sim \hat{g}_2$ in $G$ for different $g_1, g_2 \in N_G(h)$, then $\chi_{\hat{g}_1}(q) = \chi_{\hat{g}_2}(q)$.

This theorem is sometimes an origin of non-trivial identities and product formulas for the lattice theta-functions, and below we examine such examples.

#### $\mathfrak{gl}(N)$ case. Here any element is conjugated to a product of cycles of length one (see the exact definition of shifted $r$-charge in (3.18)):

$$[l_i e^{2\pi ir_i}] \sim \prod_{j=0}^{l-1} [1, e^{2\pi i v_j}]$$

(4.22)

where $v_j = r + \frac{1-2j}{2l}$. One gets therefore an identity

$$\sum_{k_1 + \ldots + k_N = 0} q^{\frac{1}{2} \sum_{i=1}^{N} (v_i + k_i)^2} \eta(q)^N = \sum_{n_1 + \ldots + n_K = 0} q^{\sum_{i=1}^{K} (n_i + l_i r_i)^2} \prod_{i=1}^{K} \eta(q^{1/l_i})$$

(4.23)
where \( v = v_1^{(l_1,r_1)} \oplus \ldots \oplus v_K^{(l_K,r_K)} \). All conformal dimensions for vanishing \( r \)-charges are conveniently absorbed by the Dedekind eta-functions \( \eta(q) = q^{1/24} \prod_{n=1}^{\infty} (1 - q^n) \).

This equality of characters can be checked by direct computation, see (A.17) in Appendix A for \( S = \{0\} \). For a single cycle \( K = 1 \) this gives a product formula for the lattice \( A_{N-1} \)-theta function (A.16), which for \( N = 2 \)

\[
\sum_{\vec{n} \in \mathbb{Q}} q^{\frac{1}{2}(\vec{n} + \vec{n})^2} = \Theta_{D_N} (\vec{n} | q) = \frac{\eta(q)^{N+1} \eta(q^{1/(N-1)})}{\eta(q^{1/2}) \eta(q^{1/2(N-1)})}
\]

(4.26)

was known yet to Gauss and has been originally used by Al. Zamolodchikov in the context of twist-field representations of the Virasoro algebra.

**\( so(2N) \) case.** For the conjugacy classes of the first type we have again (4.22), or

\[
[l, e^{2\pi i r}]_+ \sim \prod_{j=0}^{l-1} [1, e^{2\pi i v_j}]_+
\]

(4.25)

which leads to very similar identities to the \( \mathfrak{gl}(N) \)-case. For example, one can easily rederive the product formula (17) for the \( D \)-lattice theta function

\[
\sum_{\vec{n} \in \mathbb{Q}_{D_N}} q^{\frac{1}{2}(\vec{n} + \vec{n})^2} = \Theta_{D_N} (\vec{n} | q) = \frac{\eta(q)^{N+1} \eta(q^{1/(N-1)})}{\eta(q^{1/2}) \eta(q^{1/2(N-1)})}
\]

(4.26)

for \( \vec{n} = \vec{\rho} / h \), where the structure of product in the r.h.s. again comes from the characteristic polynomial of the Coxeter element of the Weyl group \( \mathfrak{w}(D_N) \). Here \( h = 2(N-1) \) is the Coxeter number, and \( \vec{\rho} = (N-1, N-2, \ldots, 1, 0) \) is the Weyl vector, corresponding to the twist field with dimension \( \Delta = \Delta^0 = \frac{N(N-1)}{4(N-1)} \), and the easiest way to derive (4.26) is to use (A.19) from Appendix A.

For another type of the conjugacy classes \([l]_-\), the situation is more tricky. The corresponding \( \eta \)-fermion

\[
\eta(z) = z^{-\frac{l}{2}} \sum_{k \in \mathbb{Z}} \frac{\eta_k}{z^{\frac{k}{2}}}
\]

(4.27)

can be separated into the parts with fixed monodromies around zero:

\[
\eta(a) = z^{-\frac{l}{2}} \sum_{k \in \mathbb{Z}} \frac{\eta_{a+2l-k}}{z^{\frac{k}{2}+a}},
\]

(4.28)

so that the only non-trivial OPE is between \( \eta(a) \) and \( \eta_{2l-a} \). In particular, \( \eta(0) \) and \( \eta(l) \) are self-conjugated Ramond (R) and Neveu-Schwarz (NS) fermions, which can be combined into new \( \bar{\eta} \) fermion, whereas all other components can be considered as charged twisted fermions \( \bar{\psi}, \psi^* \):

\[
\bar{\psi}(a)(z) = \eta(a)(z), \quad \bar{\psi}^*(a)(z) = \eta_{2l-a}(z), \quad a = 1, \ldots, l-1
\]

\[
\bar{\eta}(z) = \eta(0)(z) + \eta(l)(z)
\]

(4.29)

Therefore one gets equivalence

\[
[l]_- \sim [1]_- \cdot \prod_{j=1}^{l-1} [1, e^{2\pi i v_j}],
\]

(4.30)

\footnote{Notation \( \vec{v} \oplus \vec{u} \) means \( (v_1, \ldots, v_k) \oplus (u_1, \ldots, u_m) = (v_1, \ldots, v_k, u_1, \ldots, u_m) \).}
\[ \tilde{v}_j^{(l)} = \frac{k}{2}. \]

Moreover, if we take the product of two cycles \([1]_-\), then we can combine a pair of \(R\)-fermions and a pair of \(NS\)-fermions into two complex fermions with charges 0 and \(\frac{1}{2}\), therefore
\[ [1]_- [1]_- \sim [1, 1]_+ [1, -1]_+ \quad (4.31) \]

This means literally that a pair of \(\eta\)-fermions is equivalent to two charged bosons: one with charge \(v = 0\) and another one with charge \(v = \frac{1}{2}\). Equivalence between these two representations leads to the simple identity (B.24), (B.25):
\[\frac{2q_{\frac{1}{2}}}{\prod_{n=1}^{\infty} (1 - q^{n+\frac{1}{2}})^2} = \sum_{k,n \in \mathbb{Z}} q_{\frac{1}{2}k^2+\frac{1}{2}(k+\frac{1}{2})^2} \prod_{n=1}^{\infty} (1 - q^n)^2 \quad (4.32)\]

Using this identity we can remove a pair of \([1]_-\) cycles from (4.10) shifting \(K' \mapsto K' - 2\), and add two more directions to the lattice of charges \(B_K \mapsto B_{K+2}\) with corresponding \(r\)-charges 0 and \(\frac{1}{2}\).

**so(2N) case, \(K' = 0\).** We have the consequence of identity (A.17) for the case \(S = 2\mathbb{Z}:\)
\[\sum_{\vec{k} \in Q_{DN}} q_{\frac{1}{2}} \frac{1}{\prod_{i=1}^{N} (v_i+k_i)^2} = \prod_{i=1}^{K} \frac{\eta(q)^{l_i}}{\eta(q^{2})} \sum_{\vec{n} \in Q_{DK}} q_{\frac{1}{2}} \frac{1}{\prod_{i=1}^{K} (n_i+l_i,r_i)^2} \quad (4.33)\]

where \(v = v_1^{(l_1,r_1)} + \ldots + v_K^{(l_K,r_K)}\).

**so(2N) case, \(K' > 0; so(2N+1), K' > 0\).** In these cases everything can be expressed in factorized form using (A.19) and checked explicitly, so these cases are not very interesting.

**so(2N+1) case, NS fermion.** Here in addition to all identities that we had in the \(so(2N)\) case, we have two more identities that appear because of the fact that we can combine \(NS\) (or \(R\)) fermion with a pair of \(NS, R\) fermions to get one complex fermion with twist 0 (or twist \(\frac{1}{2}\)) and one \(R\)-fermion (or \(NS\)-fermion). Thus
\[ [1] \cdot [1]_- \sim [-1] \cdot [1, 1]_+ \]
\[ [-1] \cdot [1]_- \sim [1] \cdot [1, -1]_+ \quad (4.34) \]

Thanks to these identities in the cases \(K' \neq 0\) we can transform any character with \(NS\) fermion to a character with \(R\) fermion, and vice versa.

### 4.6 Twist representations and modules of \(W\)-algebras

By definition, all our twisted representations of the Kac-Moody algebra are twist-field representations of the \(W\)-algebra. As was explained in previous section, if \(g_1 = \Omega g_2 \Omega^{-1}\), then conjugation by \(\Omega\) transforms the \(g_1\)-twisted representation to the \(g_2\)-twisted representation. Moreover, such conjugation transforms the \(W\)-algebra generators expressed through the \(g_1\)-twisted fermions to those, expressed through the \(g_2\)-twisted fermions, with a single exception:
if $\Omega \in O(n) \setminus SO(n)$, the conjugation by $\Omega$ changes the sign of the last generator $V(z)$, see (2.24). For odd $n$ this is equivalent to the action of the operator $(-1)^F$ on representations of $W$ algebra, but for even $n$ this is an external automorphism of the $W$-algebra (coming from external automorphism of $D_N$).

Therefore, the representations of $W$-algebra corresponding to conjugated $g$-twists are isomorphic, except for the case when $\Omega \in O(2N) \setminus SO(2N)$ – where only external automorphism of $W$-algebra maps one representation to another. The last detail is not crucial if twist $g$ commutes with a certain element of $O(2N) \setminus SO(2N)$ – in this case any conjugation $\Omega$ can be reduced to the conjugation by $SO(2N)$. This happens when $g$ belongs to the class $\prod_{j=1}^{n} [1, e^{2\pi i v_j}]_+$ with some $v_k = 0$ or $v_k = \frac{1}{2}$; for example, it can be obtained from a pair of minus-cycles, or from some plus-cycle with the fine-tuned $r$-charge.

It is sufficient to consider the case of twisting by $g \in H$, since any element of $N_G(h)$ is conjugated to an element from $H$. In this case subspaces of $\mathcal{H}_g$ with all fixed fermion charges become representations of $W$-algebra\footnote{This is a common well-known procedure, see e.g. [26] and references therein.}. The $r$-charges of the corresponding representations are given by shifts of the vector $\vec{r} = \frac{\log q}{2\pi i}$ by root lattice of $\mathfrak{g}$.

The explicit formulas are given below, but we want first to comment the irreducibility of representations. The Verma modules of $W$-algebras are irreducible if

\[ (\alpha, r) \notin \mathbb{Z}, \]  

see [28], [27] (in particular Theorem 6.6.1) or [29] (eq (4.4)). For generic $r$ this condition is satisfied and all modules, arising in the decomposition (subspaces of $\mathcal{H}_g$ with all fixed fermion charges), are Verma modules due to coincidence of the characters.

If $g$ comes from the element of $N_G(h)$ with nontrivial cyclic structure, then $r$ is not necessarily generic. For $\mathfrak{gl}(N)$ case, as follows (4.22), the $r$-charges corresponding to a single cycle do satisfy (4.35), and for different cycles this condition also holds provided $r$ are generic (no relations between $r$ from different cycles). The same argument works for $\mathfrak{so}(2N)$ with “plus-cycles”, but if we have at least two “minus-cycles”, the corresponding $r$-charges can violate condition (4.35), and not only Verma modules arise in the decomposition over irreducible representations.

In any case we have an identity of characters

\[ \chi_\varphi(q) = \chi_0(q)\hat{\chi}_\varphi(q) \]  

where $\chi_0(q)$ is the character of Verma module, and $\hat{\chi}_\varphi(q)$ is the character of the space of highest vectors. Hence, there is a non-trivial statement that all coefficients of the power expansion of the ratios $\chi_\varphi(q)/\chi_0(q)$ are positive integers, which can be proven using identities, derived in the previous section.

The list of characters of the Verma modules, appeared above, is:

- $\mathfrak{gl}(N)$, $\mathfrak{so}(2N)$ (NS sector). Algebra is generated by $N$ bosonic currents, each of them producing $\prod_{n>0}(1-q^n)$, so the character is

\[ \chi_0(q) = \frac{1}{\prod_{n=1}^{\infty}(1 - q^n)^N} \]  

(4.37)
• $\text{so}(2N)$ (R sector). One of these currents, $V(z)$, becomes Ramond, with half-integer modes:
\[
\chi_0(q) = \frac{1}{\prod_{n=1}^{\infty} (1 - q^n)^{N-1} \prod_{n=0}^{\infty} (1 - q^{\frac{1}{2} + n})}
\]  
(4.38)

• $\text{so}(2N + 1)$ (NS sector). One current, $V(z)$, becomes Neveu-Schwarz fermion, so taking into account its parity we get
\[
\chi_0^\pm(q) = \prod_{n=0}^{\infty} (1 \pm q^{\frac{1}{2} + n}) \prod_{n=1}^{\infty} (1 - q^n)^N
\]  
(4.39)

• $\text{so}(2N + 1)$ (R sector). In the case of Ramond fermion $V(z)$ character $\chi^-(q)$ vanishes because fermionic zero mode produces equal numbers of states with opposite fermionic parities:
\[
\chi^+_0(q) = 2 \prod_{n=1}^{\infty} (1 + q^n) \prod_{n=1}^{\infty} (1 - q^n)^N
\]  
\[
\chi^-(q) = 0
\]  
(4.40)

$\mathfrak{gl}(N)$ case. Any element is conjugated to a product of cycles of length 1, so
\[
\hat{\chi}_{\hat{g}}(q) = q^{A^0} \sum_{\bar{n} \in Q_{A_{N-1}}} q^{\frac{1}{2}(v + \bar{n})^2}
\]  
(4.41)

$\text{so}(2N)$ case, $K' = 0$. Any element is conjugated to $\prod_{j=1}^{N} [1, e^{2\pi v_j}]_+$, so
\[
\hat{\chi}_{\hat{g}}(q) = q^{A^0} \sum_{\bar{n} \in Q_{D_N}} q^{\frac{1}{2}(v + \bar{n})^2}
\]  
(4.42)

$\text{so}(2N)$ case, $K' > 0$, NS-sector. Again, any element is conjugated to $\prod [1, e^{2\pi v_j}]_+$, so
\[
\hat{\chi}_{\hat{g}}(q) = 2^{K'-1} q^{A^0} \sum_{\bar{n} \in Q_{B_N}} q^{\frac{1}{2}(v + \bar{n})^2}
\]  
(4.43)

$\text{so}(2N)$ case, R-sector. Here any element is conjugated to $[1]_+ \prod_{j=1}^{N-1} [1, e^{2\pi v_j}]_+$, so
\[
\hat{\chi}_{\hat{g}}(q) = 2^{K'} q^{A^0} \sum_{\bar{n} \in Q_{B_{N-1}}} q^{\frac{1}{2}(v + \bar{n})^2}
\]  
(4.44)

because contribution from the cycle $[1]_-$ to the denominator cancels contribution from the Ramond boson $V(z)$.

$\text{so}(2N + 1)$ case, $K' = 0$, NS fermion. Here one has two non-trivial characters
\[
\hat{\chi}^+_g(q) = q^{A^0} \sum_{\bar{n} \in Q_{B_N}} q^{\frac{1}{2}(v + \bar{n})^2}
\]
\[
\hat{\chi}^-_g(q) = q^{A^0} \left( \sum_{\bar{n} \in Q_{D_N}} q^{\frac{1}{2}(v + \bar{n})^2} - \sum_{\bar{n} \in Q_{D_N}} q^{\frac{1}{2}(v + \bar{n})^2} \right)
\]  
(4.45)
5 Characters from lattice algebras constructions

5.1 Twisted representation of \( \hat{g}_1 \)

Now we reformulate the results of previous sections using the notion of twisted representations of vertex algebras. Recall the corresponding setting (following, for example, [16]). Let \( V \) be a vertex algebra (equivalently vacuum representation of the vertex algebra), and \( \sigma \) be an automorphism of \( V \) of finite order \( l \). Then \( V = \oplus V_k \), where \( V_k = \{ v \in V | \sigma v = \exp(2\pi ik/l)v \} \). The \( \sigma \)-twisted module is a vector-space \( M \) endowed with a linear map from \( V \) to the space of currents

\[
v \mapsto A_v(z) = \sum_{m \in \mathbb{Z}} a_m(v) z^{-m-1}, \quad v \in V, \quad a_m(v) \in \text{End}(M).
\]

Such correspondence should be \( \sigma \)-equivariant, namely

\[
A_{\sigma v}(z) = A_v(e^{2\pi i} z)
\]

giving the boundary conditions for the currents, and agree with the vacuum vector and relations in \( V \). In particular, it follows from the \( \sigma \)-equivariance (5.2), that if \( v \in V_k \) then \( A_v(z) \in z^{-k/l} \mathbb{C}[z, z^{-1}] \).

Consider now a Lie group \( G \) (either \( GL(N) \) or \( SO(2N), N \geq 2 \)), with \( g = \text{Lie}(G) \) being the corresponding Lie algebra. Denote by \( V(g) \) the irreducible vacuum representation of \( \hat{g} \) of the level one. This space has a structure of the vertex algebra, i.e. for any \( v \in V(g) \) one can assign the current \( A_v(z) \), this space of currents is generated by the currents \( J_{\alpha\beta}(z) \) from sect. 2.

The vertex algebra \( V(g) \) is a lattice vertex algebra. Let \( Q_g \) denote the root lattice of \( g \), and introduce rank of \( g \) bosonic fields with the OPE \( \varphi_i(z) \varphi_j(w) = -\delta_{ij} \log(z-w) + \text{reg} \), and the stress-energy tensor \( T(z) = -\frac{1}{2} \sum_j : \partial \varphi_j(z) \partial \varphi_j(z) : \); then the currents of \( V(g) \) can be presented in the bosonized form

\[
: \prod_i \partial^{a_i} \varphi_i \exp(\sum_a \alpha_a \varphi_i(z)) :,
\]

where \( \alpha = (\alpha_1, \ldots, \alpha_n) \in Q_g \) and \( a_i, m \) are any positive integers, while the stress-energy tensor corresponding to standard conformal vector \( \frac{1}{2} \sum J_{j,n}^2 |0 \rangle = \tau \in V(g) \) (here \( J_{j,n} \) are modes of the field \( i \partial \varphi_j(z) \)). The group \( G \) acts on \( V(g) \), and in order to use lattice algebra description we consider only the subgroup \( N_G(\mathfrak{h}) \subset G \) which preserves the Cartan subalgebra.

In [16] the representations of the lattice vertex algebra, twisted by automorphisms, arise from isometries of the lattice \( Q_g \). Here we restrict ourselves to the isometries provided by action of the Weyl group \( \mathcal{W} \) (this case was actually considered in [30] without language of twisted representations). Let \( s \in \mathcal{W} \) be an element of the Weyl group, by \( g \) we denote its lifting to \( G \), in other words \( g \in N_G(\mathfrak{h}) \) such that adjoint action \( g \) on \( \mathfrak{h} \) coincides with \( s \). We
to consider representation twisted by such \( g \). Setting of [16] and [30] works for special \( g \), for example such \( g \) should have finite order, but we will expand this to the generic \( g \in N_G(\mathfrak{h}) \). Clearly, the conformal vector \( \tau \) is invariant under the adjoint action of \( N_G(\mathfrak{h}) \).

The \( g \)-twisted representations of \( V(\mathfrak{g}) \) in [16] are defined as a direct sum of twisted representations of \( \hat{\mathfrak{h}} \). By \( \{ e^{2\pi i \theta_{\text{adj}, k}} \} \) we denote eigenvalues of \( s \), or of the adjoint action \( g_{\text{adj}} \) on \( \mathfrak{h} \), we set \( -1 < \theta_{\text{adj}, k} \leq 0 \), by \( \{ J_k \in \mathfrak{h} \} \) - the corresponding eigenvectors, and define the currents

\[
J_k(z) = \sum_{n \in \mathbb{Z}} J_{k, \theta_{\text{adj}, k} + n} z^{-\theta_{\text{adj}, k} - n - 1}
\]  

A \( g \)-twisted representation of the Heisenberg algebra \( \hat{\mathfrak{h}} \) is a Fock module \( F_\mu \) with the highest weight vector \( v_\mu \)

\[
J_{k, \theta_{\text{adj}, k} + n} v_\mu = 0, \quad n > 0, \quad J_{k, 0} v_\mu = \mu(J_k) v_\mu, \quad \theta_{\text{adj}, k} = 0.
\]

generated by creation operators \( J_{k, \theta_{\text{adj}, k} + n}, \ n \leq 0 \). Here \( \mu \in \mathfrak{h}^*_0 \), where \( \mathfrak{h}_0 \) is \( g_{\text{adj}} \)-invariant subspace of \( \mathfrak{h} \).

It has been proven in [16] that twisted representations of \( V(\mathfrak{g}) \) have the structure

\[
M(s, \mu_0) = \bigoplus_{\mu \in \mu_0 + \pi_s} Q_\mu F_\mu \otimes \mathbb{C}^{d(s)}
\]  

for certain finite set of \( \mu_0 \in \mathfrak{h}^*_0 \). Here \( \pi_s \) denotes projection from \( \mathfrak{h}^* \) to \( \mathfrak{h}^*_0 \), corresponding to the element \( s \in \mathfrak{h} \) for the chosen adjoint action \( g_{\text{adj}} \). For any root \( \alpha \) the corresponding current \( J_\alpha(z) \) acts from \( F_\mu \) to \( F_{\mu + \pi_s} \) and equals to the linear combination of vertex operators. Number \( d(s) \) denotes the defect of the element \( s \in \mathfrak{h} \), its square is defined by

\[
d(s)^2 = |(Q_\mu \cap \mathfrak{h}^*_0)/(1 - s) P_\mu|.
\]

Here \( P_\mu \) denotes weight lattice of \( \mathfrak{g} \), \( \mathfrak{h}^*_0 \) denotes the space of linear functions vanishing on \( \mathfrak{h}^*_0 \), \( | \cdot | \) stands for the number of elements in the group. It can be proven that for any \( s \) the numbers \( d(s) \) is integer. In our case (\( GL(N) \) and \( SO(n) \) groups) this number always equals to some power of 2.

Formula (5.6) allows to calculate the character of module \( M \), i.e. the trace of \( q^{L_0} \). First, notice that the character of the Fock module \( F_\mu \) equals

\[
\chi_\mu(q) = \prod_s \prod_{n=1}^{\infty} (1 - q^{\theta_{\text{adj}, k} + n})
\]  

where \( \Delta_\mu \) is an eigenvalue of \( L_0 \) on the vector \( v_\mu \). The value of \( \Delta_\mu \) consists of two contributions. The first comes from the terms with \( \theta_{\text{adj}} = 0 \), and, as follows from (5.5), is equal to \( \frac{1}{2} (\mu, \mu) \). The second contribution comes from the normal ordering. The vectors \( J_k \in \mathfrak{h} \), corresponding to \( \theta_{\text{adj}, k} \neq 0 \) can be always arranged into orthogonal pairs \( (J_1, J_{1'}) \), \( (J_2, J_{2'}) \), ... with complementary eigenvalues \( \theta_{\text{adj}, k} + \theta_{\text{adj}, k'} = -1 \). After normal ordering of the corresponding currents one gets

\[
J_k(z) J_{k'}(w) = \sum_{n, m \in \mathbb{Z}} J_{k, n, m + \theta} \frac{J_{k', m - \theta}}{w^{n + \theta + 1}} \sum_{n, m \geq 0} J_{k, n + \theta} \frac{J_{k', m - \theta}}{w^{n + \theta + 1}} + \sum_{n \geq 0} (n + \theta) \frac{w^{n + \theta - 1}}{z^{n + \theta + 1}}
\]  

\[
+ \sum_{n \in \mathbb{Z}, m < 0} J_{k', m - \theta} \frac{J_{k, n + \theta}}{w^{m - \theta + 1}} z^{n + \theta + 1} + \sum_{n \geq 0} (n + \theta) \frac{w^{n + \theta - 1}}{z^{n + \theta + 1}}
\]  

\[11 \text{There is also “degenerate” case } J_k = J_{k'} \text{ for } \theta_{\text{adj}, k} = \theta_{\text{adj}, k'} = -\frac{1}{2}. \]
where \( \theta = \theta_{\text{Adj},k} \). The last term in the r.h.s., which appears due to \([J_{k,n+\theta}, J_{k',m-\theta}] = (n + \theta)\delta_{n+m,0}\) also gives a nontrivial contribution to the action of \( L_0 \) on highest vector \( v_\mu \), since

\[
\sum_{n>0} (n + \theta) \frac{w^{n+\theta-1}}{z^{n+\theta+1}} = \frac{(1 + \theta)w^{-\theta} + (-\theta)w^{1+\theta}z^{-1-\theta}}{(z - w)^2} = \frac{1}{z-w} \frac{\theta(1 + \theta)}{2w^2} + \text{reg}
\]

(5.10)

Altogether one gets

\[
\Delta_\mu = \frac{1}{2}(\mu, \mu) - \sum_k \theta_{\text{Adj},k} \frac{(1 + \theta_{\text{Adj},k})}{4}
\]

(5.11)

and therefore, finally for the character of \( J_0 \)

\[
\text{Tr}q^{L_0} \bigg|_{M(s,\mu_0)} = q^{\frac{1}{4} \sum_k \theta_{\text{Adj},k} (1 + \theta_{\text{Adj},k})} \frac{d(s) \sum_{\mu \in \mu_0 + \pi_w Q} q^{\frac{1}{2}(\mu, \mu)}}{\prod_{i=1}^{N} \prod_{n=1}^{\infty} (1 - q^{\theta_{\text{Adj},i} + n})}
\]

(5.12)

Recall that the initial weight \( \mu_0 \) in the setting of \([16]\) should belong to the finite set in \( h_0^* \) (or \( h_0^*/\pi_w Q \)). But we will generalize such representations and take any \( \mu_0 \in h_0^* \). This can be viewed as a twisting by more general elements \( g \in N_G(h) \), which can have infinite order. Actually the corresponding elements are representatives of the conjugacy classes of \( N_G(h) \) used in sect. 3.

5.2 Calculation of characters

**GL(N) case** The root lattice \( Q_{\text{gl}(N)} = Q_{\text{A}_{N-1}} \) is generated by vectors \( \{e_i - e_j\} \), where \( \{e_1, \ldots, e_N\} \) denote the vectors of orthonormal basis in \( \mathbb{R}^N \). Assume that \( s \in W \) is a product of disjoint cycles of lengths \( l_1, \ldots, l_K \), then without loss of generality the action of such elements can be defined as \( (e_1 \mapsto e_2 \mapsto \ldots \mapsto e_{l_1} \mapsto e_1), (e_{l_1+1} \mapsto e_{l_1+2} \mapsto \ldots \mapsto e_{l_1+l_2} \mapsto e_{l_1+1}), \ldots \).

In this case \( h_0^* \) (the \( s \)-invariant part of \( h^* \)) is generated by the vectors

\[
f_1 = e_1 + \ldots + e_{l_1}, \quad f_2 = e_{l_1+1} + \ldots + e_{l_1+l_2}, \ldots
\]

(5.13)

while \( \pi_s Q_{\text{gl}(N)} \) is generated by the vectors \( \frac{1}{l_j}f_i - \frac{1}{l_j}f_j \), so one can present any element of \( \pi_s Q_{\text{gl}(N)} \) as \( \sum \frac{1}{l_j}n_j f_j \) with \( \sum n_j = 0 \) and identify with that from \( Q_{\text{gl}(K)} \). Let \( \mu_0 = \sum_j r_j f_j \). Then the formula (5.12) takes here the form

\[
\text{Tr}(q^{L_0}) \bigg|_{M(s,\mu_0)} = q^{\frac{1}{4} \sum_j (n_j l_j \mu_j)} \frac{\sum_{\mu \in \mu_0 + \pi_w Q} q^{\frac{1}{2}(\mu, \mu)}}{\prod_{i=1}^{K} \prod_{n=1}^{\infty} (1 - q^{n/l_j})},
\]

(5.14)

where, since for any length \( l \) cycle \( \theta_{\text{Adj},k} = -k/l \),

\[
\Delta_\mu^0 = \sum_{j=1}^{K} \sum_{i=1}^{l_j} i(l_j - i) = \frac{K}{4} \sum_{j=1}^{l_j} \frac{l_j^2 - 1}{24l_j}
\]

(5.15)

This formula coincides with (4.14), and the reason is that the corresponding element from \( N_{\text{GL}(N)}(h) \) is exactly (3.18), \( g = \prod_{j=1}^{K} [l_j, e^{2\pi i r_j}] \). Indeed, let \( \alpha = e_a - e_b \), where \( a \) belongs to the cycle \( j \) and \( b \) belongs to the cycle \( j' \) then the current \( J_\alpha(z) \) shifts \( L_0 \) grading by \( r_j - r_{j'} + [\text{rational number with denominator } l_j, l_{j'}] \).
**SO(2N) case**  The root lattice $Q_{SO(2N)} = Q_{DN}$ is generated by the vectors \(\{e_i - e_j, e_i + e_j\}\), where again $e_1, \ldots, e_N$ denote the basis in $\mathbb{R}^N$. As we already discussed in sect. 3 there are two types of the Weyl group elements, the first type just permutes $e_i$, while the second type permutes $e_i$ together with the sign changes.

The first case almost repeats the previous paragraph, without loss of generality we assume that the Weyl group element acts as \((e_1 \mapsto e_2 \mapsto \ldots \mapsto e_l \mapsto e_1), (e_{l+1} \mapsto e_{l+2} \mapsto \ldots \mapsto e_{l+1})\), where $l_1, \ldots, l_K$ are again the lengths of the cycles. The s-invariant part of $h^e_0$ is generated by the same “averaged” vectors \([5.13]\), while $\pi_s Q_{DN}$ is generated by the vectors \(\frac{1}{l_i} f_i - \frac{1}{l_j} f_j, \frac{1}{l_i} f_i + \frac{1}{l_j} f_j\). In other words, $\pi_s Q_{DN}$ consist of vectors $\sum_{j=1}^{n} \frac{1}{l_j} f_j$, where $(n_1, \ldots, n_k) \in Q_{SO(2K)}$. Let $\mu_0 = \sum_j r_j f_j$, then the character formula \([5.12]\) for this case acquires the form

\[
\text{Tr}(q^{L_0})|_{M(s, \mu_0)} = q^{\Delta_0} \sum_{j=1}^{K} \frac{q^{\sum_j (n_j + l_j r_j)^2}}{\prod_{j=1}^{K} \prod_{n=1}^{\infty} (1 - q^{n/l_j})} \text{ (5.16)}
\]

and coincides with \([4.7]\). Here $\Delta_0$ is defined in \([5.13]\). The corresponding element from $N_{SO(2N)}(h)$ has the form $\prod_{j=1}^{K} [l_j, e^{2\pi i r_j}]_+$ in the notations of sect. 3 (see \([3.31]\)).

For the second type (the corresponding element from $N_{SO(2N)}(h)$ has the form $\prod_{j=1}^{K} [l_j, e^{2\pi i r_j}]_+$, $\prod_{j=1}^{K'} [l_j]_-$) one can present the Weyl group element as product of $K$ disjoint cycles of lengths $l_1, \ldots, l_K$ which just permute $e_i$, and $K'$ cycles of lengths $l'_1, \ldots, l'_K'$ which permute $e_i$ with signs, see \([3.31]\). Now, without loss of generality, we assume that $s$ acts as \((e_1 \mapsto e_2 \mapsto \ldots \mapsto e_l \mapsto e_1), (e_{l+1} \mapsto e_{l+2} \mapsto \ldots \mapsto e_{l+1})\), \((e_{l+1} \mapsto e_{l+2} \mapsto \ldots \mapsto e_{l+1})\), \((e_{l+1} \mapsto e_{l+2} \mapsto \ldots \mapsto e_{l+1})\), where $L = l_1 + \ldots + l_K$. The s-invariant part of $h^e_0$ is generated by the same vectors \([5.13]\), while $\pi_s Q_{DN}$ is generated by the vectors $\frac{1}{l_j} f_i$. One can say that $\pi_s Q_{DN}$ consists of the vectors $\sum_{j=1}^{n_j} f_j$, where $(n_1, \ldots, n_k) \in Q_{SO(2K+1)} = Q_{BN}$, so that for the character formula one gets

\[
\text{Tr}(q^{L_0})|_{M(s, \mu_0)} = q^{\Delta_0} \sum_{j=1}^{K} \frac{q^{2^{K'/2-1} \sum (2i)(2l'_i - 2i + 1)}}{\prod_{j=1}^{K} \prod_{n=1}^{\infty} (1 - q^{n/l_j})} \text{ (5.17)}
\]

where, since in addition to $[l]_+$-cycles with $\theta_{Adj,k} = -k/l$ one now has $[l']_-$-cycles with $\theta'_{Adj,k} = -(k - \frac{1}{2})/l'$,

\[
\Delta_0 = \sum_{j=1}^{K} \sum_{i=1}^{l_j} \frac{i(l_j - i)}{4l_j^2} + \sum_{j=1}^{K'} \sum_{i=1}^{l'_j} \frac{(2i - 1)(2l'_i - 2i + 1)}{16l'_j^2} = \sum_{j=1}^{K} \frac{l_j^2 - 1}{24l_j} + \sum_{j=1}^{K'} \frac{2l'_j^2 + 1}{48l'_j} \text{ (5.18)}
\]

This formula coincides with \([4.10]\). The number $2^{K'/2-1}$ equals to $d(\sigma)$, this is the first case where this number is nontrivial. Note, that we consider here only internal automorphisms, i.e. $K'$ is even.

Recall also (see sect. 4.5) that if $g, g' \in N_G(h)$ are conjugate in $G$ then corresponding characters $\text{Tr}(q^{L_0})|_{M(s, \mu_0)}$ and $\text{Tr}(q^{L_0})|_{M(s', \mu_0)}$ are equal.

28
5.3 Characters from principal specialization of the Weyl-Kac formula

Fix element $g \in G$ of finite order $l$. The $g$-twisted representations of $V(\mathfrak{g})$ are representations of the affine Lie algebra twisted by $g$. Recall that these twisted affine Lie algebras $\widehat{\mathcal{L}}(\mathfrak{g}, g)$ are defined in [15, Sec 8] as $g$ invariant part of $\mathfrak{g}[t, t^{-1}] \oplus \mathbb{C}k$ where $g$ acts as

$$g(t^j \otimes J) = e^{-jt} t^j \otimes (g J g^{-1}), \text{ where } \epsilon = \exp(2\pi i/l), \quad g(k) = k. \quad (5.19)$$

By definition $g$ is an internal automorphism, therefore the algebra $\widehat{\mathcal{L}}(\mathfrak{g}, g)$ is isomorphic to $\widehat{\mathfrak{g}}$ (see Theorem [15, 8.5]), though natural homogeneous grading on $\widehat{\mathcal{L}}(\mathfrak{g}, g)$ differs from the homogeneous grading on $\widehat{\mathfrak{g}}$.

Therefore the $g$-twisted representations of $V(\mathfrak{g})$ as a vector spaces are integrable representations of $\widehat{\mathfrak{g}}$ [12]. Their characters can be computed using the Weyl-Kac character formula. This formula has simplest form in the principal specialization, i.e. computed on the element $q^{\rho_\vee} \in \widehat{G}$. Here $\rho_\vee \in \mathfrak{h} \oplus \mathbb{C}k$ such that $\alpha_i(\rho_\vee) = 1$, for all affine simple roots $\alpha_i$ (including affine root $\alpha_0$). Then the character of integrable highest weight module with the highest weight $\Lambda$ equals (see [13 eq. (10.9.4)])

$$\text{Tr}(q^{\rho_\vee/h})|_{\Lambda} = q^{\Lambda(\rho_\vee)/h} \prod_{\alpha^i \in \Delta_+^0} \left(1 - q^{(\Lambda + \rho, \alpha_\vee)/h}\right)^{\text{mult}(\alpha_\vee)} \quad , \quad (5.20)$$

where $\Delta_+^0$ is the set of all positive (affine) coroots. Here $h$ is the Coxeter number, it will be convenient to use $q^{\rho_\vee/h}$ instead of $q^{\rho_\vee}$. The weight $\rho$ is defined by $(\rho, \alpha_\vee^i) = 1$ for all simple coroots $\alpha_i$ (including affine root $\alpha_0$).

The grading above in this section was the $L_0$ grading, and it was obtained using the twist by the element $g \in N_G(\mathfrak{h})$. Now we take certain $g$ such that $g$-twisted $L_0$ grading coincides with principal grading in (5.20). We take $g$ in Cartan subgroup $H$ and, as was explained above, choice $g$ corresponds to the choice of $\mu_0$ in (5.12).

In the principal grading used in (5.20) deg $E_{\alpha_i} = \frac{1}{h}$ for all simple roots $E_{\alpha_i}$ (including affine root $\alpha_0$). Therefore $\mu_0 \in P_\mathfrak{g} + \frac{1}{h} \mathbb{P}$, where $P_\mathfrak{g}$ is the weight lattice for $\mathfrak{g}$. $\mathbb{P}$ is defined by the formula $(\mathbb{P}, \alpha_i) = 1$ for all simple roots [13].

Below we write explicit formulas for characters of twisted representation corresponding to such $g$ (and such $\mu$). In the simply laced case, computing the characters using two formulas (5.12) and (5.20) one gets an identity, which is actually the Macdonald identity [17].

In notation for root system we follow [17] and [15]. Below we consider roots as vectors in the linear space, generated by $e_1, \ldots, e_n, \delta, \Lambda_0$, and coroots -- in the space generated by $e^\vee_1, \ldots, e^\vee_n, K, d$. The pairing between these dual spaces given by $(e_i, e^\vee_j) = \delta_{ij}$, $(\Lambda_0, K) = (\delta, d) = 1$ while all other vanish.

---

[12] Note that we get only level 1 integrable representation of $\widehat{\mathfrak{g}}$ since $V(\mathfrak{g})$ was defined above as a lattice vertex algebra, i.e. vacuum representation of the level $k = 1$

[13] Note the difference between $\rho$ and $\mathbb{P}$: first was defined by pairing with simple coroots (including affine one) and the second is defined by scalar products with (non affine) roots. In the simply laced case conditions in terms of roots and coroots are equivalent and we have $\rho = \mathbb{P} + h\Lambda_0$.
GL(N) case. Root system is $A_{N-1}^{(1)}$ (affine $A_{N-1}$) dual root system is also $A_{N-1}^{(1)}$.

Simple roots: $\alpha_0 = \delta - e_1 + e_N$, $\alpha_i = e_i - e_{i+1}, 1 \leq i \leq N - 1$

Simple coroots: $\alpha_0^\vee = K + e_N^\vee - e_1^\vee$, $\alpha_i^\vee = e_i^\vee - e_{i+1}^\vee, 1 \leq i \leq N - 1$

Real coroots: $mK + e_i^\vee - e_j^\vee, m \in \mathbb{Z}, i \neq j$

Imaginary coroots: $mK$ of multiplicity $N, m \in \mathbb{Z}$.

Level $k = 1$ weights: $\Lambda_0, \Lambda_j = \Lambda_0 + \sum_{i=1}^{j} e_i, 1 \leq j \leq N - 1$

$$h = N, \rho = \frac{1}{2} \sum_{i=1}^{N} (N - 2i + 1)e_i + N\Lambda_0, \quad \overline{\rho} = \frac{1}{2} \sum_{i=1}^{N} (N - 2i + 1)e_i.$$  \hspace{1cm} (5.21)

Note that the multiplicity of imaginary roots is $N$ instead on $N - 1$ since we consider $G = GL(N)$ instead of $SL(N)$, and the corresponding affine algebra differs by one additional Heisenberg algebra.

The computation of the denominator in (5.20), using (5.21) gives

$$\prod_{\alpha^\vee \in \Delta_+^\vee} \left(1 - q^{(\rho, \alpha^\vee)/h}\right)^{\text{mult}(\alpha^\vee)} = \prod_{k=1}^{\infty} \left(1 - q^{k/N}\right)^N$$  \hspace{1cm} (5.22)

while for the numerator (the same for all level $k = 1$ weights) one gets

$$\prod_{\alpha^\vee \in \Delta_+^\vee} \left(1 - q^{(\Lambda_0^\vee + \rho, \alpha^\vee)/h}\right)^{\text{mult}(\alpha^\vee)} = \prod_{k=1}^{\infty} \left(1 - q^{k/N}\right)^{N-1}$$  \hspace{1cm} (5.23)

so that the character (5.20) in principal specialization

$$q^{-\Lambda(\rho^\vee)/h} \text{Tr}(q^{\rho^\vee/h}) |_{\Lambda_0} = \frac{1}{\prod_{k=1}^{\infty} \left(1 - q^{k/N}\right)^N}$$  \hspace{1cm} (5.24)

One can compare the last expression with the formula (5.12) using the choice of $\mu_0$, as explained above. We get an identity

$$\sum_{\alpha \in Q_{sl(N)}} q^{\frac{1}{2}(\alpha + \frac{1}{N}\overline{\rho}, \alpha + \frac{1}{N}\overline{\rho})} \prod_{k=1}^{\infty} \left(1 - q^{k/N}\right)^N = \frac{1}{\prod_{k=1}^{\infty} \left(1 - q^{k/N}\right)^N}.$$  \hspace{1cm} (5.25)

which is a particular case of formula (4.23) from sect. 4.5 and again reproduces the product formula for the lattice $A_{N-1}$-theta function (A.16).

Recall that the r.h.s. of (5.25) also has an interpretation of a character of the twisted Heisenberg algebra. This twist of the Heisenberg algebra emerges in the representation twisted by $g$ with $g_{\text{Adj}}$ acting as the Coxeter element of the Weyl group, hence r.h.s. of (5.25) equals to the r.h.s. of (5.14) for a single cycle $K = 1, l = N$. This $g$ is conjugate to used above in computing of l.h.s., therefore the characters of the twisted modules should be the same. The construction of level one representations in terms of principal Heisenberg subalgebra is well-known, see [31, 32]. Another interpretation of the l.h.s in (5.25) is the sum of characters of the $W$-algebra namely $W$ algebra of $\mathfrak{gl}(N)$, (see sect. 4.6).
\textbf{SO}(2N) case.} Root system \(D_N^{(1)}\) (affine \(D_N\)), the dual root system is also \(D_N^{(1)}\).

Simple roots: \(\alpha_0 = \delta - e_1 - e_2, \quad \alpha_i = e_i - e_{i+1}, 1 \leq i < N, \quad \alpha_N = e_{N-1} + e_N\)

Simple coroots: \(\alpha_0^\vee = K - e_1^\vee - e_2^\vee, \quad \alpha_i^\vee = e_i^\vee - e_{i+1}^\vee, 1 \leq i < N, \quad \alpha_N^\vee = e_{N-1}^\vee + e_N^\vee\)

Real coroots: \(mK + e_i^\vee - e_j^\vee, \quad mK + e_i^\vee + e_j^\vee, \quad mK - e_i^\vee - e_j^\vee, m \in \mathbb{Z}, i \neq j\)

Imaginary coroots: \(mK\) of multiplicity \(N, m \in \mathbb{Z}\)

\(k = 1\) weights: \(\Lambda_0, \quad \Lambda_1 = e_1 + \Lambda_0, \quad \Lambda_{N-1} = \frac{1}{2} \sum_{i=1}^{N} e_i + \Lambda_0, \quad \Lambda_N = \frac{1}{2} \sum_{i=1}^{N} e_i - e_N + \Lambda_0\) \quad (5.26)

\(h = 2N - 2, \quad \rho = \sum_{i=1}^{N} (N - i) e_i + (2N - 2) \Lambda_0, \quad \overline{\rho} = \sum_{i=1}^{N} (N - i) e_i.\)

Now we again just compute the denominator

\[
\prod_{\alpha^\vee \in \Delta_+^\vee} \left(1 - q^{(\Lambda + \rho, \alpha^\vee)/h}\right)^{\text{mult}(\alpha^\vee)} = \prod_{k=1}^{\infty} \left(1 - q^{k/(2N-2)}\right)^{N} \quad (5.27)
\]

and the numerator (the same for all \(k = 1\) weights)

\[
\prod_{\alpha^\vee \in \Delta_+^\vee} \left(1 - q^{(\rho, \alpha^\vee)/h}\right)^{\text{mult}(\alpha^\vee)} = \prod_{j=1}^{N-1} \prod_{k=1}^{\infty} \left(1 - q^{k - \frac{2j-1}{2N-2}}\right)^{N+1} \prod_{k=1}^{\infty} \left(1 - q^{k - \frac{1}{2}}\right) \quad (5.28)
\]

in (5.20), giving for the character

\[
q^{-\Lambda(\rho^\vee)/h} \text{Tr}(q^{\rho^\vee/h})|_{\Lambda} = \frac{1}{\prod_{j=1}^{N-1} \prod_{k=1}^{\infty} \left(1 - q^{k - \frac{2j-1}{2N-2}}\right) \prod_{k=1}^{\infty} \left(1 - q^{k - \frac{1}{2}}\right)}. \quad (5.29)
\]

As in previous case, comparing this with the formula (5.6), one gets an identity

\[
\frac{\sum_{\alpha \in \Delta_{D_N}} q^{\frac{1}{2} \left(\alpha, \frac{1}{2} \pi \alpha + \frac{1}{2} \pi \rho\right)}}{\prod_{k=1}^{\infty} \left(1 - q^k\right)^N} = \frac{1}{q^{2k^2}(\pi \rho)} \quad (5.30)
\]

where the r.h.s. can be interpreted as a character of the representation of Heisenberg algebra twisted by \(g\) such that \(g_{\text{Ad}}\) is Coxeter element. Again, this is the same as construction of level \(k = 1\) representation in terms of principal Heisenberg subalgebra from [31, 32]. The l.h.s formula (5.30) can be also interpreted as the sum of characters of the \(W(\mathfrak{so}(2N))\)-algebra, (see sect. 4.6).

By now in this section we have considered only the simply laced case – the only one, when the algebra \(V(\mathfrak{g})\) is lattice algebra or, in other words, when the level \(k = 1\) representations can be constructed as a sum of representations of the Heisenberg algebra. However, the formula (5.20) is valid for any affine Kac-Moody algebra. Below we consider the case \(G = SO(2N+1),\) where the level \(k = 1\) representations can be constructed using free fermions.
$SO(2N+1)$, $N > 2$ case. Root system is $B^{(1)}_N$ (affine $B_N$), the dual root system is $B^{(1,\vee)}_N = A^{(2)}_{2N-1}$ (affine twisted $A_{2N-1}$)

Simple roots: $\alpha_0 = \delta - e_1 - e_2$, $\alpha_i = e_i - e_{i+1}$, $1 \leq i \leq N-1$, $\alpha_N = e_N$.

Simple coroots: $\alpha_0^\vee = K - e_1^\vee - e_2^\vee$, $\alpha_i^\vee = e_i^\vee - e_{i+1}^\vee$, $1 \leq i \leq N-1$, $\alpha_N = 2e_N^\vee$.

Real coroots: $2mK \pm 2e_i$, $mK \pm e_i \mp e_j$, $mK \pm e_i \pm e_j$, $1 \leq i < j \leq N$, $m \in \mathbb{Z}$.

Imaginary coroots: $(2m - 1)K$ of multiplicity $N - 1$, $m \in \mathbb{Z}$

$2mK$ of multiplicity $N$, $m \in \mathbb{Z} \setminus \{0\}$.

$k = 1$ weights: $\Lambda_0$, $\Lambda_1 = \Lambda_0 + e_1$, $\Lambda_N = \Lambda_0 + \frac{1}{2} \sum_{i=1}^N e_i$

$h = 2N$, $\rho = \sum_{j=1}^N (N - j + \frac{1}{2})e_j + (2N - 1)\Lambda_0$, $\varpi = \sum_{j=1}^N (N - j + 1)e_j$.

Compute again the denominator

$$\prod_{\alpha^\vee \in \Delta^\vee_+} \left(1 - q^{(\frac{\alpha^\vee}{2N})} \right)^{\text{mult}(\alpha^\vee)} = \prod_{k=1}^\infty \left(1 - q^{\frac{k}{2N}}\right)^N \prod_{k=1}^\infty \left(1 - q^{\frac{2k-1}{2N}}\right)$$ (5.32)

and the numerator in the formula (5.20). Now the numerator for $\Lambda = \Lambda_0$ and $\Lambda = \Lambda_1$ is the same

$$\prod_{\alpha^\vee \in \Delta^\vee_+} \left(1 - q^{(\frac{\alpha^\vee + \Lambda_0}{2N})} \right) = \prod_{\alpha^\vee \in \Delta^\vee_+} \left(1 - q^{(\frac{\alpha^\vee + \Lambda_1}{2N})} \right) = \prod_{k=1}^\infty \left(1 - q^{\frac{k}{2N}}\right)^N \prod_{k=1}^\infty (1 + q^k)$$ (5.33)

but for $\Lambda = \Lambda_N$ it is different

$$\prod_{\alpha^\vee \in \Delta^\vee_+} \left(1 - q^{(\frac{\alpha^\vee + \Lambda_N}{2N})} \right) = \prod_{k=1}^\infty \left(1 - q^{\frac{k}{2N}}\right)^N \prod_{k=1}^\infty (1 + q^{k-\frac{1}{2}}),$$ (5.34)

Here we used the identities (B.12) and $\prod_{k=1}^\infty \left(1 - q^{2k-1}(1 - q^{k-1/2})^{-1} = \prod_{k=1}^\infty (1 + q^{k-1/2})$. It is convenient to consider the direct sums of two representations $L_{\Lambda_0} \oplus L_{\Lambda_1}$ and $L_{\Lambda_N} \oplus L_{\Lambda_N}$ since these sums have construction in terms of fermions. Using (5.20) one gets

$$q^{-\Lambda_0(\rho^\vee)/h} \text{Tr}(q^{\rho^\vee}/h)|_{L_{\Lambda_0}} + q^{-\Lambda_1(\rho^\vee)/h} \text{Tr}(q^{\rho^\vee}/h)|_{L_{\Lambda_1}} = 2 \prod_{k=1}^\infty \frac{(1 + \frac{k^2}{2})}{(1 - q^{\frac{2k-1}{2N}})},$$

$$q^{-\Lambda_N(\rho^\vee)/h} \text{Tr}(q^{\rho^\vee}/h)|_{L_{\Lambda_N}} = 2 \prod_{k=1}^\infty \frac{(1 + \frac{k^2}{2})}{(1 - q^{\frac{2k-1}{2N}})}.$$ (5.35)

The r.h.s. of these equations suggests the existence of the construction of these representation in terms of $N$-component twisted (principal) Heisenberg algebra and additional fermion (in NS and R sectors correspondingly), exactly this construction has been considered in sect. 3.4.

On the other hand these characters can be rewritten in terms of the simplest $B$-lattice
theta-functions just using the Jacobi triple product identity

\[ 2 \prod_{k=1}^{\infty} \frac{1 + q^k}{(1 - q^{\frac{2k-1}{2N}})} = \prod_{k=1}^{2N} \prod_{i=0}^{\infty} \frac{1 + q^{k-\frac{1}{2}}}{(1 - q^{k})^{\frac{1}{N}}} = \]

\[ = \sum_{n_1,\ldots,n_N \in \mathbb{Z}} q^{\frac{1}{2} \sum_{j=1}^{N} (n_j^2 + \frac{1}{N} n_j)} \prod_{k=1}^{\infty} \frac{1 + q^{k-\frac{1}{2}}}{(1 - q^{k})^{\frac{1}{N}}} \]

\[ = q^{-\frac{(N+1)(2N+1)}{48N}} \sum_{\alpha \in \mathcal{Q}_{B_N}} q^{\frac{1}{2} \sum_{j=1}^{N} (m_j^2 + \frac{1}{N} m_j)} \prod_{k=1}^{\infty} \frac{1 + q^{k-\frac{1}{2}}}{(1 - q^{k})^{\frac{1}{N}}}, \tag{5.36} \]

and

\[ 2 \prod_{k=1}^{\infty} \frac{1 + q^{k-\frac{1}{2}}}{(1 - q^{\frac{2k-1}{2N}})} = 2 \prod_{k=1}^{2N-1} \prod_{i=0}^{\infty} \frac{1 + q^{k-\frac{1}{2}}}{(1 - q^{k})^{\frac{1}{N}}} \prod_{k=1}^{\infty} \frac{1 + q^{k-\frac{1}{2}}}{(1 - q^{k})^{\frac{1}{N}}} = \]

\[ = \sum_{n_1,\ldots,n_N \in \mathbb{Z}} q^{\frac{1}{2} \sum_{j=1}^{N} (n_j^2 + \frac{1}{N} n_j)} \prod_{k=1}^{\infty} \frac{1 + q^{k-1}}{(1 - q^{k})^{\frac{1}{N}}} \]

\[ = q^{-\frac{(N+1)(2N-1)}{48N}} \sum_{\alpha \in \mathcal{Q}_{B_N - \Lambda_0} \Lambda_N - \Lambda_0} q^{\frac{1}{2} \sum_{j=1}^{N} (m_j^2 + \frac{1}{N} m_j)} \prod_{k=1}^{\infty} \frac{1 + q^{k-1}}{(1 - q^{k})^{\frac{1}{N}}}, \tag{5.37} \]

where \( \Lambda_N - \Lambda_0 \) is the highest weight of the spinor representation of \( SO(2N + 1) \). The r.h.s. of these formulas are the characters of sums of nontwisted representations of \( N \)-component Heisenberg algebra with additional infinite-dimensional Clifford algebra (or real fermion). Another point of view that the r.h.s. are the characters of sums of representations of \( W(B_N) \)-algebra \([33]\).

Finally, let us point out, that for the root system \( B_2^{(1)} = C_2^{(1)} \) (affine \( B_2 \)), the dual roots system is \( C_2^{(1),\check{\nu}} = D_3^{(2)} \) (affine twisted \( D_3 \)).

Simple roots: \( \alpha_0 = \delta = -2e_1, \quad \alpha_1 = e_1 - e_2, \quad \alpha_2 = 2e_2. \)

Simple coroots: \( \alpha_0^\vee = K - e_1^\vee, \quad \alpha_1^\vee = e_1^\vee - e_2^\vee, \quad \alpha_2^\vee = e_2^\vee. \)

Real coroots: \( mK \pm e_1^\vee, \quad mK \pm e_2^\vee, \quad 2mK \pm e_1^\vee \pm e_2^\vee, \quad 2mK \pm e_1^\vee \mp e_2^\vee, m \in \mathbb{Z}. \)

Imaginary coroots: \( (2m - 1)K \) of multiplicity 1, \( m \in \mathbb{Z} \)

\[ 2mK \) of multiplicity 2, \( m \in \mathbb{Z} \setminus \{0\}. \)

\[ h = 4, \quad \rho = 2e_1 + e_2 + 3\Lambda_0, \quad \overline{\rho} = \frac{3}{2} e_1 + \frac{1}{2} e_2. \]

the computation leads to result, coinciding with formulas \([5.32], [5.33], [5.34]\) for \( N = 2 \). Though the root system here has a bit different combinatorial structure, the fermionic construction is the same, using 5 real fermions.

6  **Exact conformal blocks of** \( W(\mathfrak{so}(2N)) \) **twist fields**

6.1  **Operator algebra structure**

Now we are going to compute certain conformal blocks. We denote by \( |\check{g}\rangle \) the highest weight vector of the representation of twisted Heisenberg \( \widehat{h} \). We denote corresponding field by \( \mathcal{O}_{\check{g}}. \)
The fields $\mathcal{O}_{g}$ are primary fields for W algebra, so we compute conformal blocks for this algebra. But our theory has more symmetry, it contains fermions and bosons with nontrivial boundary conditions \((3.10)\) and \((3.11)\). The presence of such operators provides additional restriction of the fusion of two fields

$$[\mathcal{O}_{g_1}] \mathcal{O}_{g_2} = \sum [\mathcal{O}_{\bar{g}}]$$ \hspace{1cm} (6.1)

First, the monodromy of the fused field should equal to the product of the monodromies $h = g_1 g_2$. Second, we have a selection rule in terms of $r$-charges. Namely, for any zero mode in $\hat{h}$, untwisted with respect to both $g_1$, $g_2$, corresponding $r$ charge for $\hat{h}$ equals to the sum of $r$ charges of $g_1$, $g_2$. In particular, we have equality for total $r$ charges $h = \hat{g}_1 \hat{g}_2$. As an opposite example, if $g_1$, $g_2$ are both diagonal (this corresponds to trivial the element of the Weyl group), then all $r$ charges of $h$ equal the sum of $r$ charges for $g_1$ and $g_2$.

In principle, such conformal block for twist fields can be studied for any $g \in G$, see \cite{9} about their relation to the isomonodromy deformations. But here we restrict ourselves to the case $g \in N_G(\mathfrak{h})$. If $g$ corresponds to nontrivial element of the Weyl group, then corresponding fields are special, for example in case $G = GL(2)$ all fields, corresponding to transposition, have conformal dimension $\frac{1}{16}$. The corresponding conformal blocks were found by Al. Zamolodchikov in \cite{14}. Here we generalize his construction, the answer is given in terms of the geometry of the branched cover.

### 6.2 Global construction

It has been shown in \cite{13} that conformal block of the generic $W(\mathfrak{g}(N))$ twist fields is given by explicit formula, analogous to the famous Zamolodchikov’s conformal blocks of the Virasoro twist fields with dimensions $\Delta = \frac{1}{16}$ \cite{14}. To generalize the construction of \cite{13} to all twist fields $\{\mathcal{O}_g | g \in N_G(\mathfrak{h})\}$ considered in this paper, one needs to glue local data in the vicinity of all twist field to some global structure. We consider below such construction for $G = O(2N)$, since it can be entirely performed in terms of twisted bosons.

First, let us remind the local data in the vicinity of $\mathcal{O}_{\hat{g}}(0)$ already discussed in sect. 3:

- $2l$-fold cover $z = \xi^{2l}$ with holomorphic involution $\sigma : \xi \mapsto -\xi$ without stable points except the twist field positions.
- Fermionic field $\eta(\xi)$ with exotic OPE $\eta(\xi)\eta(\sigma(\xi')) \sim \frac{1}{\xi - \xi'}$. On the sheets, connected to each other by $[l, e^{2\pi i}]_+$, one can identify $\eta(\xi)$ with ordinary complex fermion $\psi(\xi) = \eta(\xi), \eta(\sigma(\xi)) = \psi^*(\xi)$, in this case $\sigma$ permutes $\psi \leftrightarrow \psi^*$.
- Bosonic field $J(z) = (\eta(\sigma(z))\eta(z))$, which is antisymmetric $J(\sigma(z)) = -J(z)$ under the action of involution $\sigma$, and has first-order poles coming from zero-mode charges in the branch-points corresponding to cycles of type $[l, e^{2\pi i}]_+$.

Now we want to compute spherical $2M$-point conformal block

$$\mathcal{G}_0(q_1, \ldots, q_{2M}) = \langle \mathcal{O}_{\hat{g}_1}(q_1) \mathcal{O}_{\hat{g}_2}(q_2) \cdots \mathcal{O}_{\hat{g}_{2M-1}}(q_{2M-1}) \mathcal{O}_{\hat{g}_{2M}}(q_{2M}) \rangle_{\tilde{h}_1, \ldots, \tilde{h}_k},$$ \hspace{1cm} (6.2)

\footnote{This is difficult to do using just W algebra symmetry, the space of conformal blocks is infinite dimensional, they depend not only on the highest weights of external fields (so contrary to characters, the answer will depend on $\hat{g}$, not just on its orbit under the action of $N_G(\mathfrak{h})$).}
where we fix intermediate fields $\mathcal{O}_{h_k}$ such that $h_k \in G$ are diagonal, $g_{2k-1}g_{2k} = h_k$, $r$, charges for $h_k$ should be compatible with fusion $\mathcal{O}_{g_{2k-1}}\mathcal{O}_{g_{2k}}(q_2)$ to $\mathcal{O}_{h_k}$, and fusion of all $\mathcal{O}_{h_k}$ should equal to identity. In the discussion below we forget about fermion and consider only the twisted boson with current $J(z)$. Now let us list the field-theoretic properties which fix this conformal block uniquely.

Let $g$ corresponds to the cycle $[l,\lambda]_+$, denote by $[0]_\tilde{g}$ the highest vector of the module of twist-field $\mathcal{O}_{\tilde{g}}$. Then we have $J_{k/l>0}[0]_\tilde{g} = 0$. Therefore the most singular term of the 1-form $J(z)dz$ in the vicinity of the twist field $\mathcal{O}_{\tilde{g}}$ is the simple pole

$$J(z)dz \sim \frac{dz}{z},$$

where the residue $r$ is the $r$-charge. Similarly, if $g$ corresponds to the cycle $[l]_-$, then $J(z)dz$ do not have pole in the vicinity of $\mathcal{O}_{\tilde{g}}$.

For two fields $\mathcal{O}_{g_{2k-1}}(z)\mathcal{O}_{g_{2k}}(z')$ as above (i.e. corresponding to the opposite elements of the Weyl group) the operator product expansion in the channel corresponding to $\tilde{h}_k$ has the form

$$\mathcal{O}_{g_{2k-1}}(z)\mathcal{O}_{g_{2k}}(z') \sim \left(z - z'\right)^{\Delta_{h_k} - \Delta_{g_{2k-1}} - \Delta_{g_{2k}}} \mathcal{V}_{J}(z') + \text{descendants}$$

where $\mathcal{V}_{J}(z') = \mathcal{O}_{h_k}(z')$ is a field with fixed charges $\tilde{a} \in \mathfrak{h}$ (we used another letter $V$ in order to stress that this is just exponent of the bosonic field). Hence

$$\frac{1}{2\pi i} \oint_{\gamma_{z,z'}} J(\xi) d\xi \mathcal{O}_{g_{2k-1}}(z)\mathcal{O}_{g_{2k}}(z') = a_j \mathcal{O}_{g_{2k-1}}(z)\mathcal{O}_{g_{2k}}(z')$$

where contour $\gamma_{z,z'}$ is the $j$-th preimage of the contour encircling two points $z, z'$ on the base. We identify such contours with the A-cycles on the cover, and corresponding $a$'s with A-periods of 1-form $J(z)dz$.

The standard OPE of two currents

$$J(z)J(z')dzdz' = \frac{dzdz'}{(z - z')^2} + 4\mathcal{T}(z') + \ldots$$

gives the stress-energy tensor

$$\mathcal{T}(z) = \sum_{\pi_{2N}(\xi) = z} \bar{\mathcal{T}}(\xi)$$

$$\mathcal{T}(z)\mathcal{O}_g(0) = \frac{\Delta_{\tilde{g}}}{z^2} \mathcal{O}_g(0) + \frac{1}{z} \partial \mathcal{O}_g(0) + \ldots$$

and non-standard coefficient (4 instead of 2) arises due to involution $\sigma$. Summarizing these facts we get:

- 2$N$-sheet branched cover $\pi_{2N} : \Sigma \to \mathbb{P}^1$ with the branch points $\{q_1, \ldots, q_{2M}\}$ and ramification structure defined by the elements of Weyl group corresponding to $\{g_1, g_2, \ldots, g_{2M-1}, g_{2M}\}$.

  In particular, $\Sigma$ is a disjoint union of two curves when all $\{g_i\}$ do not contain $[l]_-$ cycles.

\footnote{In principle, we may choose any monodromies, though in this way we will get complicated twisted representations in the intermediate channels, but as in [13] we restrict ourselves to simpler, but still quite general case of pairwise inverse (up to diagonal factors $h_i$) monodromies.}
• Involution of this cover $\sigma : \Sigma \rightarrow \Sigma$ with the stable points coinciding with $[l]_-$ cycles

$$\sigma \quad \Sigma \xrightarrow{\pi_2} \tilde{\Sigma} \xrightarrow{\pi_N} \mathbb{CP}^1$$ (6.8)

Projections and involution are shown on the commutative diagram: $\pi_{2N} = \pi_N \circ \pi_2$, $\pi_2 \circ \sigma = \pi_2$.

• Odd meromorphic differential $dS(\sigma(\xi)) = -dS(\xi)$ with the poles in preimages of $q_i$ and residues given by corresponding $r$-charges.

• Symmetric bidifferential $d\Omega(\xi, \xi')$, satisfying $d\Omega(\sigma(\xi), \xi') = -d\Omega(\xi, \xi')$, with two poles:

$$d\Omega_2(\xi, \xi') \sim \frac{d\xi d\xi'}{(\xi - \xi')^2}, \quad d\Omega_2(\xi, \xi') \sim \frac{d\xi d\xi'}{(\xi - \sigma(\xi'))^2}$$ (6.9)

and vanishing $A$-periods.

Using this data one can write for two auxiliary correlators

$$G_1(\xi|q_1, \ldots, q_{2M}) = d\xi \left( J(\xi) O_{\tilde{g}1}(q_1) O_{\tilde{g}2}(q_2) \cdots O_{\tilde{g}_{2M-1}}(q_{2M-1}) O_{\tilde{g}_{2M}}(q_{2M}) \right)$$

$$G_2(\xi, \xi') = d\xi d\xi' \left( J(\xi) J(\xi') O_{\tilde{g}1}(q_1) O_{\tilde{g}2}(q_2) \cdots O_{\tilde{g}_{2M-1}}(q_{2M-1}) O_{\tilde{g}_{2M}}(q_{2M}) \right)$$ (6.10)

Their explicit expressions

$$G_1(\xi) G_0^{-1} = dS(\xi), \quad G_2(\xi, \xi') G_0^{-1} = dS(\xi) dS(\xi') + d\Omega_2(\xi, \xi')$$ (6.11)

are fixed uniquely by their analytic behaviour. Now let us study in detail the structure of the curve $\Sigma$ in order to construct all these objects.

6.3 Curve with holomorphic involution

Involution $\sigma$ defines the two-fold cover $\pi_2 : \Sigma \rightarrow \tilde{\Sigma}$ with the total number of branch points being $2K' = 2 \sum_{i=1}^{M} K'_i$, or exactly the total number of $[l]_-$ cycles in all elements $\{g_k\}$. The Riemann-Hurwitz formula $\chi(\Sigma) = 2 \cdot \chi(\tilde{\Sigma}) - \#BP$ then gives for the genus

$$g(\Sigma) = 2g(\tilde{\Sigma}) + K' - 1$$ (6.12)

Then a natural way to specify the $A$-cycles on $\Sigma$ is the following [34]: first to take $A^{(1)}_1, \ldots, A^{(1)}_{\tilde{g}}$, $A^{(2)}_1, \ldots, A^{(2)}_{\tilde{g}}$ on each copy of $\tilde{\Sigma}$, where $\tilde{g} = g(\tilde{\Sigma})$; and second, all other $A$-cycles that correspond to the branch cuts of the cover, connecting the branch points of $\pi_2$: $A^{(0)}_1, \ldots, A^{(0)}_{K'-1}$. The action of involution on these cycles is obviously given by

$$\sigma(A^{(i)}_i) = A^{(2)}_i, \quad \sigma(A^{(2)}_i) = A^{(1)}_i, \quad i = 1, \ldots, \tilde{g}$$

$$\sigma(A^{(0)}_j) = -A^{(0)}_j, \quad j = 1, \ldots, K' - 1$$ (6.13)

thus we have the decomposition of the real-valued first homology group into the even and odd parts

$$H_1(\Sigma, \mathbb{R}) = H_1(\Sigma, \mathbb{R})^+ \oplus H_1(\Sigma, \mathbb{R})^-$$

$$\dim H_1(\Sigma, \mathbb{R})^+ = g(\Sigma) = \tilde{g}$$

$$\dim H_1(\Sigma, \mathbb{R})^- = \tilde{g} + K' - 1 = g_-$$ (6.14)
Compute now \( \tilde{g} = g(\tilde{\Sigma}) \) using the Riemann-Hurwitz formula for the cover of \( \mathbb{P}^1 \). Let \( K = \sum_{i=1}^{M} K_i \) be the total number of \( [l, e^{2\pi i r}]_+ \)-type cycles in all elements \( \{g_{2k-1}\} \), as well as \( K' \) serves for the type \( [l']_+ \). Then \( \chi(\Sigma) = N \cdot \chi(\mathbb{P}^1) - \#BP \) gives (cf. with the formula (2.17) of [13])

\[
\tilde{g} = 1 - N + \sum_{i=1}^{K} (l_i - 1) + \sum_{i=1}^{K'} (l'_i - 1) \tag{6.15}
\]

so that

\[
g_- = \tilde{g} + K' - 1 = \sum_{i=1}^{K} (l_i - 1) + \sum_{i=1}^{K'} l'_i - N \tag{6.16}
\]

and

\[
g = 1 - 2N + 2 \sum_{i=1}^{K} (l_i - 1) + 2 \sum_{i=1}^{K'} (l'_i - \frac{1}{2}) \tag{6.17}
\]

For our purposes the most essential is the odd part \( H_1(\Sigma, \mathbb{R})^- \) of the homology. One can see these \( g_- \) A-cycles explicitly as follows: two mutually inverse permutations of type \( [l]_+ \) produce \( l \) pairs of A-cycles \( A_i^{1,2} \) with constraints \( \sum_i A_i^{1,2} = 0 \). These cycles are permuted by \( \sigma \) (6.13), so they actually form \( l - 1 \) independent odd combinations, giving contribution to the r.h.s. of (6.16). For two mutually inverse elements of the type \( [l']_+ \) one gets instead \( 2l' \) A-cycles with constraint \( \sum_i A_i = 0 \), and with the action of involution \( \sigma : A_i \mapsto A_{i+l'} \), giving \( l' \) independent odd combinations \( \{A_i - A_{i+l'}\} \), arising in the r.h.s. of (6.16), while the extra term \(-N\) corresponds to charge conservation in the infinity.

Hence, we got \( g_- \) odd A-cycles, whose projections to \( \mathbb{P}^1 \) encircle pairs of the colliding twist fields \( O_{\tilde{g}_{2k-1}}(g_{2k-1})O_{\tilde{g}_{2k}}(g_{2k}) \) for \( k = 1, \ldots, M \), so that the integrals of

\[
\frac{1}{2\pi i} \oint_{A_i} dS = a_I, \quad I = 1, \ldots, g_-
\]

give the W-charges in the intermediate channels of conformal block (6.2). Therefore \( dS \) can be expanded

\[
dS = \sum_{I=1}^{g_-} a_I d\omega_i + \sum_{i=1}^{2M} dS_r
\]

over the odd holomorphic differentials, and meromorphic differentials of the 3-rd kind corresponding to the nonvanishing \( r \)-charges.

Now, for the bidifferential \( d\Omega_2(\xi, \xi') \) one can write

\[
d\Omega_2(\xi, \xi') = K(\xi, \xi') - K(\sigma(\xi), \xi') = 2K(\xi, \xi') - \tilde{K}(\xi, \xi') \tag{6.20}
\]

where \( K(\xi, \xi') \) is the canonical meromorphic bidifferential on \( \Sigma \) (the double logarithmic derivative of the prime form, see [34]), normalized on vanishing A-periods in each of two variables, and

\[
\tilde{K}(\xi, \xi') = K(\xi, \xi') + K(\sigma(\xi), \xi') \tag{6.21}
\]

is actually a pullback of the canonical meromorphic bidifferential on \( \tilde{\Sigma} \). Indeed, consider

\[
\delta K(\xi, \xi') = K(\xi, \xi') - K(\sigma(\xi), \sigma(\xi'))
\]

37
which is already holomorphic at $\xi = \xi'$, and $\int_{\mathcal{A}_k} \delta K(\xi, \xi') = 0$, since due to (6.13) normalization conditions do not change under involution. Thus $\delta K(\xi, \xi') = 0$ and the canonical bidifferential is $\sigma$-invariant

$$K(\sigma(\xi), \sigma(\xi')) = K(\xi, \xi')$$

(6.23)

Moreover, since

$$\tilde{K}(\xi, \xi') = \tilde{K}(\sigma(\xi), \xi') = \tilde{K}(\xi, \sigma(\xi'))$$

(6.24)

expression (6.21) actually defines the canonical bidifferential on $\tilde{\Sigma}$.

### 6.4 Computation of conformal block

Now we use the technique from [14, 13] to compute the conformal block (6.2). For the vacuum expectation value of the stress-energy tensor (6.7) one gets from (6.11), (6.20)

$$\langle T(z)\mathcal{O}_{g_1}(q_1)\mathcal{O}_{g_2}(q_2) \cdots \mathcal{O}_{g_{2M-1}}(q_{2M-1})\mathcal{O}_{g_{2M}}(q_{2M})\rangle_0^{-1} =$$

$$= \sum_{\pi_{2N}(\xi) = z} t_z(\xi) - \sum_{\pi_N(\xi) = z} \tilde{t}_z(\xi) + \frac{1}{4} \left( \frac{dS}{dz} \right)^2$$

(6.25)

where $t_z$ and $\tilde{t}_z$ are the regularized parts of the bidifferentials $K$ and $\tilde{K}$ on diagonal in coordinate $z$:

$$t_z(\xi) d\xi^2 = \frac{1}{2} \left( \lim_{\xi \to \xi'} K(\xi', \xi) - \frac{d\pi_{2N}(\xi) d\pi_{2N}(\xi')}{(\pi_{2N}(\xi') - \pi_{2N}(\xi))^2} \right)$$

$$\tilde{t}_z(\xi) d\xi^2 = \frac{1}{2} \left( \lim_{\xi \to \xi'} \tilde{K}(\xi', \xi) - \frac{d\pi_N(\xi) d\pi_N(\xi')}{(\pi_N(\xi') - \pi_N(\xi))^2} \right)$$

(6.26)

Expanding (6.25) at $z \to q_k$ one gets

$$\tilde{t}_z(\xi) = \frac{1}{12} \{\xi; z\} + \text{reg.} = \frac{1}{(z - q_k)^2} \frac{l^2 - 1}{24l^2} + \text{reg.}$$

$$t_z(\xi) = \frac{1}{12} \{\xi; z\} + \text{reg.} = \frac{1}{(z - q_k)^2} \frac{4l^2 - 1}{96l^2} + \text{reg.}$$

(6.27)

in local co-ordinates $\xi = z - q_k$, which gives for the conformal dimensions $\Delta$ of the fields $\mathcal{O}_g$ (with generic $\mathfrak{g}(2N)$ twist field of the type (1.8))

$$\Delta_g = \sum_{j=1}^{K} \frac{l_j^2 - 1}{24l_j} + \sum_{j=1}^{K'} \frac{2l_j^2 + 1}{48l_j^2} + \sum_{i=1}^{K} \frac{1}{2} l_i r_i^2 = \Delta^0_g + \sum_{i=1}^{K} \frac{1}{2} l_i r_i^2,$$  

(6.30)

\[\text{The counting here works as}\]

$$t_z - \tilde{t}_z \rightarrow 2 \sum_{j=1}^{K} t_j \frac{l_j^2 - 1}{24l_j^2} - \sum_{j=1}^{K} l_j \frac{l_j^2 - 1}{24l_j^2} = \sum_{j=1}^{K} \frac{l_j^2 - 1}{24l_j}$$

(6.28)

for the $[l]_+$-cycles, and

$$t_z - \tilde{t}_z \rightarrow 2 \sum_{j=1}^{K'} l_j \frac{4l_j^2 - 1}{96l_j^2} - \sum_{j=1}^{K'} l_j \frac{l_j^2 - 1}{24l_j^2} = \sum_{j=1}^{K'} \frac{2l_j^2 + 1}{48l_j}$$

(6.29)

for the $[l']_-$-cycles.
where the last term in the r.h.s. comes from the expansion $dS \approx r_i \frac{dz}{z - q_i} + \ldots$. Without contributions of $r$-charges this formula is equivalent to (5.18), (6.36).

From the first order poles we obtain

$$
\partial_{q_k} \log G_0(q_1, \ldots, q_{2M}) = \sum_{\pi_{2N}(\xi) = q_k} \text{Res} t_\xi(\xi)d\xi - \sum_{\pi_N(\zeta) = q_k} \text{Res} \tilde{t}_\zeta(\zeta)d\zeta + \frac{1}{4} \sum_{\pi_{2N}(\xi) = q_k} \text{Res} \frac{(dS)^2}{dz}, \quad k = 1, \ldots, 2M
$$

(6.31)

This system of equations for conformal block is obviously solved, so that we can formulate:

**Theorem 3** Conformal blocks (6.2) for generic $W(\mathfrak{o}(2N))$ twist fields are given by

$$
G_0(a, r, q) = \tau_B(\Sigma|q)\tau_B^{-1}(\tilde{\Sigma}|q)\tau_{SW}(a, r, q)
$$

(6.32)

where

$$
\partial_{q_k} \log \tau_B(\Sigma|q) = \sum_{\pi_{2N}(\xi) = q_k} \text{Res} t_\xi(\xi)d\xi
$$

$$
\partial_{q_k} \log \tau_B(\tilde{\Sigma}|q) = \sum_{\pi_N(\zeta) = q_k} \text{Res} \tilde{t}_\zeta(\zeta)d\zeta
$$

(6.33)

and

$$
\partial_{q_k} \log \tau_{SW}(a, r, q) = \frac{1}{4} \sum_{\pi_{2N}(\xi) = q_k} \text{Res} \frac{(dS)^2}{dz}, \quad k = 1, \ldots, 2M
$$

(6.34)

Equations (6.33) define so-called Bergmann tau-functions [35] for the curves $\Sigma$ and $\tilde{\Sigma}$ respectively, while the so-called Seiberg-Witten tau-function (6.34) can be read literally from [13]

$$
\log \tau_{SW}(a, r, q) = \frac{1}{4} \sum_{I,J} \text{Res} \frac{(dS)^2}{dz}, \quad k = 1, \ldots, 2M
$$

(6.35)

Equations (6.33) define so-called Bergmann tau-functions [35] for the curves $\Sigma$ and $\tilde{\Sigma}$ respectively, while the so-called Seiberg-Witten tau-function (6.34) can be read literally from [13]

$$
\log \tau_{SW}(a, r, q) = \frac{1}{4} \sum_{I,J} \text{Res} \frac{(dS)^2}{dz}, \quad k = 1, \ldots, 2M
$$

(6.35)

where $T_{IJ}$ is the $g_- \times g_-$ “odd block” of the period matrix of $\Sigma$, or the period matrix of corresponding Prym variety [34], the “odd” vector

$$
U_J(r) = \oint_{\partial_{q_k}} d\Omega = \sum_{k,\alpha} r_{k}^{\alpha} A_J(q_k^{\alpha}), \quad J = 1, \ldots, g_-
$$

(6.36)

where $q_k^{\alpha}$ are preimages of $q_i$ and $r_{k}^{\alpha}$ - corresponding $r$-charges, and $A_J(P) = \int_{P} d\omega_J$ is the Abel map to the Jacobian of $\Sigma$. The last term in the r.h.s. of (6.35) is given by

$$
Q(r) = \sum_{q_{i}^{\alpha} \neq q_{j}^{\beta}} r_{i}^{\alpha} r_{j}^{\beta} \log \theta_{*}(A(q_{i}^{\alpha}) - A(q_{j}^{\beta})) - \sum_{q_{i}^{\alpha}} l_{i}^{\alpha} (r_{i}^{\alpha})^2 \log \frac{d(z(q) - q_i)^{1/l_{i}^{\alpha}}}{h_{*}^{2}(q)}
$$

(6.37)

where $\theta_{*}$ is some odd Riemann theta-function for the curve $\Sigma$, and

$$
h_{*}^{2}(z) = \sum_{I=1}^{g} \frac{\partial \theta_{*}(0)}{\partial Z_I} d\omega_I(z)
$$

(6.38)
Remark: In the general $N > 2$ case conformal conformal block constructed above is not fixed by conjugacy classes of twists and by charges in the intermediate channels: it depends also on the geometry of the cover. This is a reminiscent of infinite-dimensional space of 3-point conformal blocks in the general case, but unlike that case now we deal only with finite-dimensional space, which can be easily studied.

6.5 Relation between $W(\mathfrak{so}(2N))$ and $W(\mathfrak{gl}(N))$ blocks

It is interesting to compare the formulas from previous section with the formulas from \[13\] for the exact $W(\mathfrak{gl}(N))$ conformal blocks. Since, as we already discussed $W(\mathfrak{so}(2N)) \subset W(\mathfrak{gl}(N))$, any vertex operator of the $W(\mathfrak{gl}(N))$ algebra is a vertex operator of its subalgebra $W(\mathfrak{so}(2N))$, and it is clear from our construction that twist fields $O_\hat{g}$ for the elements $g \sim \prod[l, e^{2\pi iv}]$, are also the twist fields for $W(\mathfrak{gl}(N))$. Moreover, the corresponding Verma modules, generated by $W(\mathfrak{so}(2N))$ and by $W(\mathfrak{gl}(N))$, actually coincide\[17\] and it means that corresponding conformal blocks of such fields in these two theories should coincide as well.

Indeed, in such a case $\Sigma = \tilde{\Sigma} \cup \overset{\sim}{\Sigma}$, and therefore $K(\xi, \xi') = 0$ if $\xi'$, $\xi$ are on different components, and $K(\xi, \xi') = \tilde{K}(\xi, \xi')$ if they are on the same component, hence

$$t_\varepsilon(z) = 2\tilde{t}_\varepsilon(z) \quad (6.39)$$

For holomorphic and meromorphic differentials, one has in this case in natural basis

$$a_I = \oint_{A_I^{(1)}} dS = \oint_{A_I^{(2)}} dS, \quad I = 1, \ldots, \tilde{g} \quad (6.40)$$

$$r^\alpha_k = \text{Res}_{q^\alpha_k} dS = \text{Res}_{\sigma(q^\alpha_k)} dS$$

for the preimages $\{q^\alpha_k\}$ on $\tilde{\Sigma}$, and the period matrix of $\Sigma$ consists of two nonzero $\tilde{g} \times \tilde{g}$ blocks:

$$\mathbf{T}^{(11)} = \mathbf{T}^{(22)} = \tilde{\mathbf{T}} \quad (6.41)$$

Under such conditions formula (6.32) turns into

$$G_0(a, r, q) = \tau_B(\tilde{\Sigma}|q)\tilde{\tau}_{SW}(a, r, q) \quad (6.42)$$

where

$$\log \tilde{\tau}_{SW}(a, r, q) = \frac{1}{2} \sum_{I, J=1}^{\tilde{g}} a_I \tilde{T}_{IJ} a_J + \sum_{I=1}^{\tilde{g}} a_I \tilde{U}_I(r) + \frac{1}{2} \tilde{Q}(r) \quad (6.43)$$

with corresponding obvious modifications of formulas (6.36) and (6.37), which gives exactly the $W(\mathfrak{gl}(N))$ conformal block in terms of the data on smaller curve $\tilde{\Sigma}$.

\[17\] These two modules coincide due to dimensional argument: they are both irreducible and have the same characters. Irreducibility follows from the fact that null-vector condition can be written as $\left(\alpha, \frac{\log g}{2\pi i}\right) \in \mathbb{Z}$ for a simple root $\alpha$, and for generic generic $r$’s it is violated, see also comments in sect. [4.6]

40
7 Conclusion

We have considered in this paper the twist fields for the W-algebras with integer Virasoro central charges, which are labeled by conjugacy classes in the Cartan normalizers $N_G(h)$ of corresponding Lie groups. In addition to the most common $W_N$-algebras, corresponding to $A$-series (or $W(gl(N)) = W_N \oplus H$, coming from $G = GL(N)$), we have extended this construction for the $G = O(n)$ case, which includes in addition to $D$-series the non simply-laced $B$-case with the half-integer Virasoro central charge.

In terms of two-dimensional conformal field theory our construction is based on the free-field representation, where generalization to the $D$-series and $B$-series exploits the theory of real fermions, which in the odd $B$-case cannot be fully bosonized, so that in addition to modules of the twisted Heisenberg algebra one has to take into account those of infinite-dimensional Clifford algebra. This construction produces representations of the W-algebras (that are at the same time twisted representations of corresponding Kac-Moody algebras), which can be decomposed further into Verma modules. To find this decomposition we have computed the characters of twisted representations, using two alternative methods.

The first one comes from bosonization of the W-algebra or corresponding Kac-Moody algebra at level one. Depending on particular element from $N_G(h)$ it identifies the representation space with a collection of the Fock modules for untwisted or twisted bosons. The essential new phenomenon, which appears in the case of orthogonal groups, is presence of different $[l]_-$ cycles in $g \in N_G(h)$ and necessity to use in such cases “exotic” bosonization for the Ramond-type fermions with non-local OPE on the cover.

Alternative method for computation of the characters uses pure algebraic construction of the twisted Kac-Moody algebras and the Weyl-Kac formula in principal gradation.

There are examples of elements $g_1, g_2$ that are not conjugated in $N_G(h)$, but conjugated in $G$. Since two different constructions with elements $g_1$ and $g_2$ give different formulations of the same representation, computation of corresponding characters $\chi_{g_1}(q)$ and $\chi_{g_2}(q)$ leads to some simple but nontrivial identities for the corresponding lattice theta-functions, $\chi_{g_1}(q) = \chi_{g_2}(q)$, which have been also proven by direct methods.

We have also derived an exact formula for the general conformal block of the twist fields in $D$-case, which directly generalizes corresponding construction for common $W_N$-algebra. The result, as is usual for Zamolodchikov’s exact conformal block, is expressed in terms of geometry of covering curve (here with extra involution), and can be factorized into the classical “Seiberg-Witten” part, totally determined by the period matrix of the corresponding Prym variety, and the quasiclassical correction, expressed now in terms of two different canonical bi-differentials. In order to expand this method for the $B$-case one has to learn more about the theory of “exotic fermions” on Riemann surfaces, probably along the lines of [36, 37], and we postpone this for a separate publication.

Another set of open problems is obviously related with generalization to other series and twisted fields related with external automorphisms. Here only the $E$-cases seem to be straightforward, since standard bosonization can be immediately applied in the simply-laced case, and there should be not many problems with the fermionic construction. However, it is not easy to predict what happens in the situation when Kac-Moody algebras at level $k = 1$ have fractional central charges, and the direct application of the methods developed in this paper is probably impossible. It is still not very clear, what is the role of these exact conformal blocks in the context of multi-dimensional supersymmetric gauge theories, since generally there is no Nekrasov combinatorial representation in most of the cases. We hope
to return to these issues in the future.

Finally, there is an interesting question of possible generalization of our approach to the twisted representations with $k \neq 1$, which has been already considered in [40]. Some overlap with our formulas with sect. 8 of this paper suggests that such generalization could exist. We hope to return to this problem elsewhere.

Acknowledgements

We are grateful to D. Adler, B. Feigin, I. Frenkel, A. Ilyina, I. Krichever, O. Lisovyy, E. Opdam, and N. Sakharova for illuminating discussions, and to the organizers of “5th workshop on Combinatorics of moduli spaces” in Moscow, “CQISS-16” at the Chern Institute of Nankai University, “Random geometry and physics” in Paris and “Progress in quantum field theory and string theory II” in Osaka, where the preliminary results of this work have been reported. The work of PG and AM was partially supported by the RSF grant No. 16-11-10160, in particular the main results of sect. 4 and the construction from sect. 6 have been obtained using support of Russian Science Foundation, the work of AM has been also partially supported by RFBR grant 17-01-00585. This work has been also funded by the Russian Academic Excellence Project ‘5-100’.

PG and AM also like to thank the KdV Institute of the University of Amsterdam, where essential part of this work has been done, and especially G. Helminck, for the warm hospitality. MB and PG are Young Russian Mathematics award winners and would like to thank its sponsors and jury.

Appendix

A Identities for lattice $\Theta$-functions

Here we present few rigorously proved identities, used to verify representation-theoretic considerations at the level of computations of characters.

A.1 First identity for $A_{N-1}$ and $D_N$ $\Theta$-functions

One can describe the lattices $A_{N-1}$, $D_N$ and $D'_N$ in a similar way:

$$A_{N-1} = \{k_1, \ldots, k_N \mid \sum_{i=1}^{N} k_i = 0\}$$

$$D_N = \{k_1, \ldots, k_N \mid \sum_{i=1}^{N} k_i \in 2\mathbb{Z}\}$$

$$D'_N = \{k_1, \ldots, k_N \mid \sum_{i=1}^{N} k_i \in 2\mathbb{Z} + 1\}$$

(A.1)
The last lattice is actually just $D_N$ lattice, but shifted by vector $(1, 0, \ldots, 0)$. So all these definitions can be rewritten as

$$L_S = \{k_1, \ldots, k_N \mid \sum_{i=1}^{N} k_i \in S\}$$  \hspace{1cm} (A.2)

where $S \subseteq \mathbb{Z}$; in our cases it should be chosen to be $\{0\}$, $2\mathbb{Z}$, and $2\mathbb{Z}+1$, respectively. Notice also that for $S = \mathbb{Z}$ we get the simplest $B_N$ lattice.

By definition

$$\Theta_{L_S}(\vec{v}; q) = \sum_{k_1, \ldots, k_N \in S} q^{\frac{1}{2}(\vec{v} + \vec{k})^2}$$  \hspace{1cm} (A.3)

For our purposes we need this function computed for the vector

$$\vec{v} = (r_1 + \frac{l_1 - 1}{2l_1}, r_1 + \frac{l_1 - 3}{2l_1}, \ldots, r_1 + \frac{1 - l_1}{2l_1}) \oplus \oplus (r_2 + \frac{l_2 - 1}{2l_2}, r_2 + \frac{l_2 - 3}{2l_2}, \ldots, r_2 + \frac{1 - l_2}{2l_2}) \oplus \ldots \oplus$$

$$\oplus (r_K + \frac{l_K - 1}{2l_K}, r_K + \frac{l_K - 3}{2l_K}, \ldots, r_K + \frac{1 - l_K}{2l_K})$$  \hspace{1cm} (A.4)

where $l_1 + \ldots + l_K = N$. Let us parameterize vector $\vec{k}$ as follows:

$$\vec{k} = (n_1, \ldots, n_1) \oplus \ldots \oplus (n_K, \ldots, n_K) + \omega_{a_1}^{(l_1)} \oplus \ldots \oplus \omega_{a_K}^{(l_K)} +$$

$$+ (\frac{a_1}{l_1}, \ldots, \frac{a_1}{l_1}) \oplus \ldots \oplus (\frac{a_K}{l_K}, \ldots, \frac{a_K}{l_K}) + \vec{m}_1 \oplus \ldots \oplus \vec{m}_K$$  \hspace{1cm} (A.5)

where $\vec{m}_i \in A_{l_i-1}$, and

$$\omega_a^{(l)} = (\frac{l-a}{l}, \ldots, \frac{l-a}{l}, \frac{-a}{l}, \ldots, \frac{-a}{l})$$  \hspace{1cm} (A.6)

so that the first number is repeated $a$ times, whereas the second one $l-a$ times. Hence, vectors $\vec{k} \in L_S$ are parameterized by vectors $\{\vec{m}_i \in A_{l_i-1}\}$ and integer numbers $\{n_i \in \mathbb{Z}; a_i \in \mathbb{Z}/l_i\mathbb{Z}\}$, restricted by

$$\sum_{i=1}^{K} (n_i l_i + a_i) \in S$$  \hspace{1cm} (A.7)

The algorithm of decomposition (A.5) works as follows: first we sum up all components of $\vec{k}$ inside each cycle – each number divided by $l_i$ gives $n_i$, whereas remainder gives $a_i$. Subtracting $(n_i, \ldots, n_i) + \omega_{a_i}^{(l_i)}$, we are left with the vectors $\{\vec{m}_i\}$ with vanishing sums of components.

Now it is easy to see that

$$\Theta(\vec{v} + \omega_{a_1}^{(l_1)} \oplus \omega_{a_2}^{(l_2)} \oplus \ldots \oplus \omega_{a_K}^{(l_K)}; q) = \Theta(\vec{v}; q)$$  \hspace{1cm} (A.8)

which follows from the fact that $\Theta(\vec{v}; q) = \Theta(\sigma(\vec{v}); q)$, where $\sigma$ is a permutation. For example, take $\sigma_a$ to be $a$-th power of the cyclic permutation, then:

$$\sigma_a\left(\frac{1-l}{2l}, \ldots, \frac{1-l}{2l}\right) = \left(\frac{l+1-2a}{2l}, \frac{l+3-2a}{2l}, \ldots, \frac{l-1}{2l}, \frac{l-1}{2l}, \ldots, \frac{l-1-2a}{2l}\right) =$$

$$= \left(\frac{1-l}{2l}, \ldots, \frac{1-l}{2l}\right) + \omega_a^{(l)}$$  \hspace{1cm} (A.9)
and therefore any vector \( \vec{v} + \omega_{a_1}^{(l_1)} \oplus \omega_{a_2}^{(l_2)} \oplus \ldots \oplus \omega_{a_K}^{(l_K)} \) can be obtained by several permutation of components of \( \vec{v} \), so the corresponding \( \Theta \)-functions are equal. Thus

\[
\Theta_{LS}(\vec{v}; q) = \sum_{\vec{m}_i \in Q_{A_{l-1}}} q^{\frac{1}{2}(\vec{v} + \vec{m}_1 \oplus \ldots \oplus \vec{m}_K + (n_1 + \frac{n_1}{4l_1}, \ldots, n_1 + \frac{n_1}{4l_1}) \oplus \ldots \oplus (n_K + \frac{n_K}{4l_K}, \ldots, n_K + \frac{n_K}{4l_K}))^2
\]  

(A.10)

turns into the sum over several orthogonal sublattices

\[
\Theta_{LS}(\vec{v}; q) = \sum_{\vec{m}_i \in Q_{A_{l-1}}} q^{\frac{1}{2}(\vec{v}^2 + \vec{m}_1 \oplus \ldots \oplus \vec{m}_K)^2}. \sum_{\sum_{i=1}^{K}(n_i l_i + a_i) \in S} q^{\frac{1}{2} \sum_{i=1}^{K}(n_i l_i + a_i)^2}
\]  

(A.11)

\[
= \prod_{i=1}^{K} \Theta_{A_{l-1}}(\hat{\rho}^{(l_i)}; q) \cdot \sum_{n_1' + \ldots + n_K' \in S} q^{\frac{1}{2} \sum_{i=1}^{K}(n_i' + r_i l_i)^2}
\]

where

\[
\hat{\rho}^{(l)} = \left\{ \frac{l - 1}{2l}, \frac{l - 3}{2l}, \ldots, \frac{1 - l}{2l} \right\}
\]  

(A.12)

One can identify the last factor in the r.h.s. with the contribution of zero modes, related to the \( r \)-charges \([13]\).

### A.2 Product formula for \( A_{N-1} \) \( \Theta \)-functions

Apply (A.11) to the simplest case of \( \Theta_{B_N}(\hat{\rho}^{(N)}; q) \) with \( S = Z \)

\[
\Theta_{B_N}(\hat{\rho}^{(N)}; q) = \Theta_{A_{N-1}}(\hat{\rho}^{(N)}; q) \cdot \sum_{n \in \mathbb{N}} q^{\frac{n^2}{2N}}
\]  

(A.13)

Using definition (A.12) and Jacobi triple product formula we get

\[
\Theta_{B_N}(\hat{\rho}^{(N)}; q) = q^{\frac{N^2 - 1}{24N}} \prod_{k=0}^{N-1} q^{\frac{k^2}{2} + \frac{N - 1 - 2k}{2N}}
\]  

(A.14)

as well as

\[
\sum_{n \in \mathbb{N}} q^{\frac{n^2}{2N}} = \prod_{k=1}^{\infty} \left( 1 + q^{\frac{k}{N}(k - \frac{1}{2})} \right)^2 \prod_{n=1}^{\infty} (1 - q^n)^N
\]  

(A.15)

Substituting into (A.13) one obtains

\[
\Theta_{A_{N-1}}(\hat{\rho}^{(N)}; q) = q^{\frac{N^2 - 1}{24N}} \prod_{k=1}^{\infty} \frac{(1 - q^k)^N}{(1 - q^k)^{\frac{N}{2}}} = \frac{\eta(q)^N}{\eta(q^{\frac{N}{2}})}
\]  

(A.16)

or the product formula \([17]\) for \( \Theta_{A_{N-1}}(\hat{\rho}^{(N)}; q) \), where the r.h.s. is expressed in terms of the Dedekind functions. Substituting this into (A.11) we get it in its final form

\[
\Theta_{LS}(\vec{v}; q) = \sum_{k_1 + \ldots + k_N \in S} q^{\frac{1}{2} \sum_{i=1}^{N}(n_i + k_i)^2} = \prod_{i=1}^{K} \frac{\eta(q)^{k_i}}{\eta(q^{\frac{k_i}{2}})} \cdot \sum_{n_1 + \ldots + n_K \in S} q^{\frac{1}{2} \sum_{i=1}^{K}(n_i + r_i l_i)^2}
\]  

(A.17)
A.3 An identity for $D_N$ and $B_N$ $\Theta$-functions

Here we show how $\Theta_{D_N}(\vec{v}^*; q)$ can be simplified if $\vec{v}^*$ contains at least one component $\frac{1}{2}$. One has then

$$\Theta_{D_N}(\vec{v}^*; q) = \Theta_{D_N}(\left(\frac{1}{2}, v_2, \ldots, v_n\right); q) = \sum_{k_1+\ldots+k_n \in \mathbb{Z}} q^{\frac{1}{2}(\vec{v}^*+\vec{k})^2} = \Theta_{D_N}(\left(-\frac{1}{2}, v_2, \ldots, v_n\right); q) = \Theta_{D_n}(\vec{v}^* - (1, 0, \ldots, 0); q)$$

(A.18)

Since for the lattices $D_N \sqcup \{D_N - (1, 0, \ldots, 0)\} = B_N$, it follows from (A.18) that

$$\Theta_{D_N}(\vec{v}^*; q) = \frac{1}{2} \Theta_{B_N}(\vec{v}^*; q) \quad (A.19)$$

B Exotic bosonizations

Here we present some details of the bosonization procedures, used in the main text.

B.1 $NS \times R$

Consider, first, construction [38, 39] relating pair (of $NS$ and $R$!) fermions to a twisted boson

$$\tilde{\phi}(t) = i \sum_{r \in \mathbb{Z} + \frac{1}{2}} J_r e^{\frac{2\pi i}{h} r^2} = i \sqrt{2} \sum_{n \in \mathbb{Z}} \frac{a_{2n+1}}{(2n+1)\xi^{2n+1}} = \phi(\xi)$$

(B.1)

with differently normalized oscillator modes $[a_M, a_N] = M\delta_{M+N,0}$ ($M, N \in 2\mathbb{Z} + 1$). Compute the correlator

$$-\langle \phi(\xi)\phi(\zeta) \rangle = 2 \sum_{n=0}^{\infty} \frac{(\zeta/\xi)^{2n+1}}{2n+1} = 2 \sum_{n=0}^{\infty} \frac{1}{2n+1} (1 - \zeta/\xi)^{-2n} = 2 \log \left( \frac{1 - \zeta/\xi}{1 - \zeta^2/\xi^2} \right) = - \log \left( \frac{\zeta + \xi}{\zeta - \xi} \right) = -[\phi_+(\xi), \phi_-(\zeta)]$$

assuming $|\xi| > |\zeta|$. Now introduce

$$\hat{\eta}(\xi) = \frac{1}{\sqrt{2}} e^{\frac{i}{2} \phi(\xi)} := \frac{1}{\sqrt{2}} e^{\frac{i}{2} \phi_-(\xi)} e^{\frac{i}{2} \phi_+(\xi)}$$

(B.3)

so that for $|\xi| > |\zeta|$

$$\hat{\eta}(\xi)\hat{\eta}(\zeta) = \frac{1}{2} e^{-(\phi_-(\xi) + \phi_-(\zeta))} e^{i(\phi_+(\xi) + \phi_+(\zeta))} e^{-i[\phi_+(\xi), \phi_-(\zeta)]} = \frac{1}{2} : e^{i(\phi(\xi) + \phi(\zeta))} : \xi - \zeta \xi + \zeta$$

(B.4)

while for $|\xi| < |\zeta|$,

$$\hat{\eta}(\zeta)\hat{\eta}(\xi) = \frac{1}{2} : e^{i(\phi(\xi) + \phi(\zeta))} : \zeta - \xi \xi + \zeta$$

(B.5)

$\text{It is more convenient to use in this section coordinate } \xi = \sqrt{t}, \text{ so analytic continuation in } t \text{ around 0 maps } \xi \text{ to } -\xi.$
It means that OPE of the $\hat{\eta}$-fields has fermionic nature:

$$\hat{\eta}(\xi)\hat{\eta}(-\zeta) = \frac{1}{2} \frac{\xi + \zeta}{\xi - \zeta} ; e^{i(\xi(\xi) - \phi(\zeta))} : \sim \frac{1}{2} \frac{\xi + \zeta}{\xi - \zeta} + \text{reg.} \sim \frac{\zeta}{\xi - \zeta} + \text{reg.}$$ \hspace{1cm} (B.6)

and in the anticommutator of components $\hat{\eta}(\xi) = \sum_{k \in \mathbb{Z}} \frac{i}{\lambda} k$

$$\{\eta, (-1)^{l} \eta\} = \int \zeta^{-1} d\zeta \int \frac{\zeta}{\zeta - \zeta} \xi^{-1} d\xi = \delta_{k+l,0}$$ \hspace{1cm} (B.7)

one gets unusual sign factor.

It is interesting to point out that the Ramond zero mode $\eta_{0}^{2} = \frac{1}{2}$ has bosonic representation

$$\sqrt{2} \eta_{0} = \int \frac{d\xi}{\xi} e^{i\phi(\xi)} e^{i\phi(\zeta)} = 1 - 2a_{-1}a_{1} + a_{-1}^{2}a_{1}^{2} - \frac{2}{9} (a_{-3} + a_{-1}) (a_{3} + a_{1}^{3}) + \ldots$$ \hspace{1cm} (B.8)

For example, the action of this operator on low-level vectors gives

$$\sqrt{2} \eta_{0} \cdot |0\rangle = |0\rangle, \quad \sqrt{2} \eta_{0} \cdot a_{-1}|0\rangle = -a_{-1}|0\rangle, \quad \sqrt{2} \eta_{0} \cdot a_{-3}|0\rangle = a_{-1}|0\rangle$$

$$\sqrt{2} \eta_{0} \cdot a_{-3}|0\rangle = \frac{1}{3} a_{-3}|0\rangle - 2a_{-1}^{3}|0\rangle, \quad \sqrt{2} \eta_{0} \cdot a_{-1}^{3}|0\rangle = -\frac{4}{3} a_{-3}|0\rangle - \frac{1}{3} a_{-1}^{3}|0\rangle$$ \hspace{1cm} (B.9)

Here in the second line one gets the matrix $\frac{1}{3} \begin{pmatrix} 1 & -2 \\ -4 & -1 \end{pmatrix}$ with the eigenvalues $\pm 1$. We also have

$$\eta_{0} \eta_{k} = -\eta_{k} \eta_{0}, \quad k \neq 0$$ \hspace{1cm} (B.10)

so one can identify $\sqrt{2} \eta_{0} = (-1)^{F_{0}}$, where $F$ is fermionic parity. Generally, algebra, generated by $\{\eta_{k}\}$, has two representations with the vacua $|0\rangle_{\pm}$, such that $\eta_{0}|0\rangle_{\pm} = \pm|0\rangle_{\pm}$. One can also take direct sum of such representations: bosonization formula in this representation looks as

$$\hat{\eta}(\xi) = \frac{\sigma^{1}}{\sqrt{2}} e^{i\phi_{-}(\xi)} e^{i\phi_{+}(\xi)}$$ \hspace{1cm} (B.11)

Existence of this bosonization at the level of characters gives us obvious identity

$$\prod_{k=0}^{\infty} \frac{1}{1 - q^{2k+1}} = \prod_{k=1}^{\infty} (1 + q^{k})$$ \hspace{1cm} (B.12)

Notice that above consideration actually concerns $R$ and $NS$ fermions because one can construct two combinations

$$\frac{1}{\sqrt{2}} (\hat{\eta}(z) - \hat{\eta}(-z)) = \sum_{p \in \mathbb{Z}^{1/2}} \frac{\eta_{2p}}{z^{p}} = i \hat{\psi}_{NS}(z)$$

$$\frac{1}{\sqrt{2}} (\hat{\eta}(z) + \hat{\eta}(-z)) = \sum_{n \in \mathbb{Z}} \frac{\eta_{2n}}{z^{n}} = \hat{\psi}_{R}(z)$$ \hspace{1cm} (B.13)
\[ J(z) = \frac{1}{z} \left( \hat{\psi}^*(\sqrt{z}) \hat{\psi}(\sqrt{z}) \right) = i \psi_{NS}(z) \psi_R(z) = \sum_{p \in \mathbb{Z} + \frac{1}{2}} \frac{J_p}{z^{p+1}} \]  

(B.14)

\[ J_p = i \sum_{n+q=p} \eta_{2q} \eta_{2n} \]

here \( t^{-\frac{1}{2}} \hat{\psi}_{NS}(\sqrt{t}) \) and \( t^{-\frac{1}{2}} \hat{\psi}_R(\sqrt{t}) \) are usual Ramond and Neveu-Schwarz fermions.

Here we consider fermion corresponding to the branch point of type \([l]_-\). This means that we should have

\[ \eta(z) \eta(\sigma(w)) \sim \frac{1}{z - w}, \]  

(B.15)

and such monodromy that \( \eta(e^{4\pi i}z) = \pm \eta(z) \). Let us use the construction form (B.1)

\[ \eta(z) = \frac{z^{-\frac{1}{2}}}{\sqrt{2l}} \hat{\eta}(z^{\frac{1}{2l}}) \]  

(B.16)

Therefore

\[ \eta(z) \eta(\sigma(w)) \sim \frac{z^{-\frac{1}{2}} w^{-\frac{1}{2}}}{2l} \frac{w^{\frac{1}{2l}}}{z^{\frac{1}{2l}} - w^{\frac{1}{2l}}} \sim \frac{1}{z - w} \]  

(B.17)

So final construction states that one should have

\[ \eta(z) = \sigma_1 \frac{z^{-\frac{1}{2}}}{2\sqrt{l}} e^{i\phi_- (z^{\frac{1}{2l}})} e^{i\phi_+ (z^{\frac{1}{2l}})} \]  

(B.18)

### B.2 \( R \times R \)

Let us take two Ramond fermions \( \psi^{(1)}, \psi^{(2)} \) and introduce

\[ \psi(z) = \frac{1}{\sqrt{2}} \left( \psi^{(1)}(z) + i \psi^{(2)}(z) \right) = \sum_{n \in \mathbb{Z}} \frac{\psi_n}{z^{n + \frac{1}{2}}} \]

\[ \psi^*(z) = \frac{1}{\sqrt{2}} \left( \psi^{(1)}(z) - i \psi^{(2)}(z) \right) = \sum_{n \in \mathbb{Z}} \frac{\psi_n^*}{z^{n + \frac{1}{2}}} \]  

(B.19)

Since there are two zero modes \( \psi_0^* \) and \( \psi_0 \), one expects to have four vacua \( |0\rangle, \psi_0|0\rangle, \psi_0^*|0\rangle, \) \( \psi_0^*\psi_0|0\rangle \).

We can mimic expansion (B.19) using fractional powers

\[ \psi(z) = \sum_{p \in \mathbb{Z} + \frac{1}{2}} \frac{\psi_{NS,p}}{z^{p + \frac{1}{2} + \sigma}}, \quad \psi^*(z) = \sum_{p \in \mathbb{Z} + \frac{1}{2}} \frac{\psi_{NS,p}^*}{z^{p + \frac{1}{2} - \sigma}} \]  

(B.20)

with \( \sigma = \frac{1}{2} \), i.e. \( \psi_n = \psi_{NS,n-\frac{1}{2}} \) and \( \psi_n^* = \psi_{NS,n+\frac{1}{2}}^* \). It means that after standard bosonization

\[ \psi(z) = e^{-i\phi_-(z)} e^{-i\phi_+(z)} e^{-Q z^0} J_0, \]

\[ \psi^*(z) = e^{i\phi_-(z)} e^{i\phi_+(z)} e^Q z^0 J_0 \]

(B.21)

one gets \( \psi_0^*|0\rangle = 0 \), and only one half of the vacuum states survive. To identify this representation with something well-known, consider the eigenvectors \( \sqrt{2}\psi_0^{(1)} |0\rangle_\pm = \pm |0\rangle_\pm \) of \( \sqrt{2}\psi_0^{(1)} = \psi_0 + \psi_0^*: \)

\[ |0\rangle_+ = \frac{1}{\sqrt{2}} \left( |0\rangle + \psi_0 |0\rangle \right), \quad |0\rangle_- = \frac{i}{\sqrt{2}} \left( |0\rangle - \psi_0 |0\rangle \right) \]  

(B.22)
Acting by $\sqrt{2}\psi_0^{(2)} = i(\psi_0^* - \psi_0)$ one gets

$$\sqrt{2}\psi_0^{(2)}|0\rangle_+ = |0\rangle_-, \quad \sqrt{2}\psi_0^{(2)}|0\rangle_- = |0\rangle_+ \tag{B.23}$$

The character of such module is given by

$$2 \prod_{k=1}^\infty (1 + q^k)^2 = q^{-\frac{1}{8}} \sum_{n \in \mathbb{Z}} q^{\frac{1}{2} n^2} \prod_{k=1}^\infty (1 - q^k) \tag{B.24}$$

where in the l.h.s. we have two Ramond fermions with two vacuum states, whereas the r.h.s. corresponds to sum over bosonic modules with half-integer vacuum $J_0$ charges. This formula is a simple consequence of the Jacobi triple product identity. Analogously we have similar formula for the bosonization of $NS \times NS$ fermions

$$\prod_{k=0}^\infty (1 + q^{\frac{1}{2} + k})^2 = \sum_{n \in \mathbb{Z}} q^{\frac{1}{2} n^2} \prod_{k=1}^\infty (1 - q^k) \tag{B.25}$$

It is the consequence of Jacobi triple product identity as well.

### B.3 $l$ twisted charged fermions

For the twisted boson

$$i\phi(z) = - \sum_{n \neq 0} \frac{J_{n/l}}{nz^{n/l}} + \frac{1}{l} J_0 \log z + Q \tag{B.26}$$

with

$$[J_{n/l}, J_{m/l}] = n\delta_{n+m,0} \quad [J_0, Q] = 1 \tag{B.27}$$

one has for $|z| > |w|$

$$\left[\phi_+(z) - \frac{i}{l} J_0 \log z, \phi_-(w) - iQ\right] = \sum_{n>0} \frac{z^{-n/l}w^{n/l}}{n} - \frac{1}{l} \log z = - \log \left(\frac{z^{1/l} - w^{1/l}}{z^{1/l} - w^{1/l}}\right) \tag{B.28}$$

where

$$i\phi_+(z) = - \sum_{n>0} \frac{J_{n/l}}{nz^{n/l}} \quad i\phi_-(z) = - \sum_{n<0} \frac{J_{n/l}}{nz^{n/l}} \tag{B.29}$$

Define two operators

$$\hat{\psi}^*(z) = z^{\frac{1}{2}} e^{i\phi(z)} := z^{\frac{1}{2l}} e^{i\phi_-(z)} e^{i\phi_+(z)} e^{Qz^{n/l}}$$

$$\hat{\psi}(z) = z^{-\frac{1}{2}} : e^{-i\phi(z)} := z^{-\frac{1}{2l}} e^{-i\phi_-(z)} e^{-i\phi_+(z)} e^{-Qz^{n/l}} \tag{B.30}$$

with the OPE

$$\hat{\psi}^*(z) \hat{\psi}(w) = \frac{(zw)^{\frac{1}{l}}}{z^{1/l} - w^{1/l}} : e^{i\phi(z) - i\phi(w)} := \frac{(zw)^{\frac{1}{l}}}{z^{1/l} - w^{1/l}} e^{i\phi_+(z) - i\phi_+(w)} e^{i\phi_-(z) - i\phi_-(w)} \left(\frac{z}{w}\right)^{J_0/l} \tag{B.31}$$
Then for the modes of their expansion

\[ \hat{\psi}^*(z) = \sum_{k \in \frac{1}{2} + \mathbb{Z}} \frac{\psi_{k/l}^*}{z^{k/l}}, \quad \hat{\psi}(z) = \sum_{k \in \frac{1}{2} + \mathbb{Z}} \frac{\psi_{k/l}}{z^{k/l}} \]  

one gets canonical anticommutation relations

\[ \{ \psi_a^*, \psi_b \} = \delta_{a+b,0} \]  

Now one can express the \( l \)-component fermions in terms of a single twisted boson

\[ \psi_a^*(z) = \frac{1}{\sqrt{l}} z^{-\frac{1}{2}} e^{i \phi_2(z)} e^{2\pi i a z}, \quad \psi_a(z) = \frac{1}{\sqrt{l}} z^{-\frac{1}{2}} e^{i \phi_2(z)} e^{2\pi i a z}, \quad a \in \mathbb{Z}/l \mathbb{Z} \]  

and it follows from (B.31), that their OPE is indeed

\[ \psi_a^*(z) \psi_\beta(w) = \frac{\delta_{a,\beta}}{z-w} + \text{reg.} \]  

The stress-energy tensor and \( U(1) \) current can be extracted from the expansion:

\[ \sum_{\alpha \in \mathbb{Z}/l \mathbb{Z}} \psi_{\alpha}(z) \psi_{\alpha}(z+\frac{t}{2}) = \frac{l}{t} + J(z) + tT(z) + \ldots \]  

Using (B.30), (B.31) and (B.34) one gets for the l.h.s.

\[ \frac{l}{t} + \sum_{\alpha \in \mathbb{Z}/l \mathbb{Z}} \left( \frac{1}{t} + \frac{t^2 - 1}{24l^2 z^2} \right) \partial \phi(z) e^{2\pi i \alpha z} + O(t^2) = \]  

\[ = \frac{l}{t} + \sum_{\alpha \in \mathbb{Z}/l \mathbb{Z}} i \partial \phi(z) e^{2\pi i \alpha z} + \frac{t}{z^2} - \frac{1}{24l} - \frac{t}{2} \sum_{\alpha \in \mathbb{Z}/l \mathbb{Z}} \partial \phi(z) e^{2\pi i \alpha z} : + O(t^2) \]  

One finds from here

\[ J(z) = \sum_{\alpha \in \mathbb{Z}/l \mathbb{Z}} i \partial \phi(z) e^{2\pi i \alpha z} = \sum_{k \in \mathbb{Z}} \frac{J_n}{z^{n+1}} \]  

\[ T(z) = \frac{l^2 - 1}{24l z^2} + \frac{1}{l} \sum_{n \in \mathbb{Z}} J_n J_k : z^{n+k+2} \]  

which already have expansions over integer powers of \( z \). Therefore

\[ L_0 = \frac{l^2 - 1}{24l} + \frac{1}{2l} J_0^2 + \frac{1}{l} \sum_{n>0} J_{-n} J_n \]  

and the character of this module is given by

\[ \text{tr} q^{L_0} = q^{\frac{l^2-1}{24l}} \sum_{n \in \mathbb{Z}} q^{\frac{(tr+n)^2}{l}} \prod_{n=1}^{\infty} (1 - q^n) \]
Important detail here is the following: monodromy transformations of fermions over the whole cycle are given by

\[ \psi^*(e^{2\pi i l} z) = (-1)^{l-1} e^{2\pi i J_0}, \quad \psi(e^{2\pi i l} z) = (-1)^{l-1} e^{-2\pi i J_0} \]  

Here the factor \((-1)^{l-1}\) comes from the factors \(z^{-\frac{1}{2}}\) and \(z^{\frac{1}{2}}\), whereas \(e^{2\pi i J_0}\) comes from \(z^{\frac{1}{2}}\). Altogether this means that twisted fermions above represent conjugacy class \([l, e^{2\pi i r}]_+\) with \(rl = J_0 \mod \mathbb{Z}\).

\[ \text{(B.42)} \]

### B.4 \( l \) charged fermions – standard bosonization

From the modes \((B.32)\) of the operators \(\hat{\psi}(z), \hat{\psi}^*(z)\) we can construct another \(l\) fermions

\[ \psi_{(a)}(z) = \frac{1}{\sqrt{l}} \sum_{p \in \mathbb{Z} + \frac{1}{2}} \frac{\psi_{a+p}}{z^{a+p+\frac{1}{2}}}, \quad \psi^*_{(a)}(z) = \frac{1}{\sqrt{l}} \sum_{p \in \mathbb{Z} + \frac{1}{2}} \frac{\psi_{-a+p}}{z^{-a+p+\frac{1}{2}}} \]  

where \( a \in \{ \frac{l-1}{2l} + r, \frac{l-3}{2l} + r, \ldots, \frac{1-l}{2l} + r \} \) \(\text{(B.44)}\)

These fermions can be bosonized in terms of \(l\) “normal”, untwisted, bosons

\[ \psi^*_{(a)}(z) = e^{i\varphi_{(a),-}(z)} e^{i\varphi_{(a),+}(z)} e^{Q_{(a)} z} z^{J_{(a),0}} \left( -1 \right)^{\sum_{b < a} J_{(b),0}} \]  
\[ \psi_{(a)}(z) = e^{-i\varphi_{(a),-}(z)} e^{-i\varphi_{(a),+}(z)} e^{-Q_{(a)} z} z^{-J_{(a),0}} \left( -1 \right)^{\sum_{b < a} J_{(b),0}} \]  

where

\[ J_{(a),0}|0\rangle = a|0\rangle \]  

\[ \text{(B.46)} \]

Computation of character in this case gives us

\[ \text{tr} q^{L_0} = \frac{\sum_{n_0,\ldots,n_{l-1}}^{l-1} q^{(r + \frac{l-1}{2l} + n_k)^2}}{\prod_{n=1}^{\infty} (1 - q^n)^l} \]  

\[ \text{(B.47)} \]

One can easily see that equality between \((B.40)\) and \((B.47)\) follows from particular case of \((A.19)\).
