JETS OF SINGULAR FOLIATIONS

EDUARDO ESTEVES

Abstract. Given a singular foliation satisfying locally everywhere the Frobenius condition, even at the singularities, we show how to construct its global sheaves of jets. Our construction is purely formal, and thus applicable in a variety of contexts.

1. Introduction

Let $M$ be a complex manifold of complex dimension $m$. A holomorphic foliation $\mathcal{L}$ of dimension $n$ of $M$ is a decomposition of $M$ in complex submanifolds, called leaves, of dimension $n$. Also, locally the leaves must pile up nicely, like the fibers of a holomorphic map. In other words, for each point $p$ of $M$ there must exist an open neighborhood $U$ and a holomorphic submersion $\varphi: U \to V$ to an open subset $V \subseteq \mathbb{C}^{m-n}$ such that the fibers of $\varphi$ are the intersection of the leaves with $U$. We say that $\varphi$ defines $\mathcal{L}$ on $U$.

A holomorphic foliation $\mathcal{L}$ of $M$ induces a vector subbundle of the tangent bundle $T_M$ of $M$: for each $p \in M$, the vector subspace of $T_{M,p}$ is the tangent space at $p$ of the unique leaf passing through $p$. Thinking in dual terms, $\mathcal{L}$ induces a surjection $w: T^*_M \to E$ from the bundle of holomorphic 1-forms to a holomorphic rank-$n$ vector bundle $E$. The bundle $E$, also denoted by $T^*_\mathcal{L}$, is regarded as the bundle of 1-forms of $\mathcal{L}$.

Not all surjections $w: T^*_M \to E$ to a holomorphic vector bundle $E$ arise from foliations. The necessary and sufficient condition for this is given by the Frobenius Theorem: locally at each point $p$ of $M$, choose a trivialization of $E$ at each $p \in M$, such that the resulting vector fields $X_1, \ldots, X_n$ induced by $w$; if their Lie brackets $[X_i, X_j]$ can be expressed as sums $\sum g_{i,j}^l X_l$, where the $g_{i,j}^l$ are holomorphic functions on a neighborhood of $p$, then $w$ arises from a foliation.

The surjection $w$ can be seen, locally on an open subset $U \subseteq M$ for which there is a submersion $\varphi: U \to V \subseteq \mathbb{C}^{m-n}$ defining $\mathcal{L}$, as the natural map $T^*_U \to T^*_U/\mathcal{L}$ from the bundle of 1-forms on $U$ to the bundle of relative 1-forms on $U$ over $V$. Also, on such a $U$, we may consider the natural surjection $J^q_U \to J^q_{U/\mathcal{L}}$ from the bundle $J^q_U$ of $q$-jets (or principal parts of order $q$) on $U$ to the bundle $J^q_{U/\mathcal{L}}$ of relative jets of $\varphi$, for each integer $q \geq 0$. These patch to form surjections $w^q: J^q_M \to J^q_{\mathcal{L}}$ to bundles $J^q_{\mathcal{L}}$ that can be regarded as the bundles of $q$-jets of the foliation.

But what happens if all the data are algebraic? More precisely, assume $M$ is algebraic, $E$ and $w$ are algebraic, and there is an algebraic trivialization of $E$ at each $p \in M$ such that the resulting vector fields $X_1, \ldots, X_n$ are involutive, i.e. satisfy $[X_i, X_j] = \sum g_{i,j}^l X_l$ for $g_{i,j}^l$ algebraic. Are the bundles $J^q_{\mathcal{L}}$ algebraic? In

principle, they are just holomorphic, since the local submersions \( \varphi \) from which they arise are just holomorphic, constructed by means of the implicit function theorem.

Moreover, it is rare for a projective manifold to admit interesting foliations. For this reason, one has started to study \textit{singular foliations}, in a variety of ways. For instance, a singular foliation of \( M \) of dimension \( n \) may be defined to be a map \( w: T^r_M \to E \) to a rank-\( n \) holomorphic vector bundle \( E \) which, on a dense open subset \( M^0 \subseteq M \), arises from a foliation \( \mathcal{L} \). We still regard \( E \) as the bundle of \( 1 \)-forms of the foliation. But the bundles of jets \( J^2_x \) are, in principle, only defined on \( M^0 \). Under which conditions do they extend to \( M \)?

In the present paper, we will show that if all the data are algebraic, then the bundles \( J^2_x \) are algebraic. Furthermore, if the same Frobenius’ conditions, appropriately formulated, are verified at each point of \( M - M^0 \), then the bundles \( J^2_x \) extend to the whole \( M \). For the proofs, we will completely bypass Frobenius Theorem, giving an entirely formal construction of the bundles of jets that applies in many categories, for instance that of differentiable manifolds, or of schemes over any base. Furthermore, not only will we consider maps to bundles \( E \), but also to sheaves of modules, locally free or not, obtaining thus sheaves of jets.

Our construction of the sheaves of jets is by “iteration”, so will only apply in characteristic zero. For an approach in positive characteristic, albeit limited in scope, see [1] or [10]. From now on, all rings are assumed to be \( \mathbb{Q} \)-algebras.

Here is what we do. Let \( X \) be a topological space, \( \mathcal{O}_B \) a sheaf of \( \mathbb{Q} \)-algebras and \( \mathcal{O}_X \) a sheaf of \( \mathcal{O}_B \)-algebras. Let \( \mathcal{F} \) be a sheaf of \( \mathcal{O}_X \)-modules and \( D: \mathcal{O}_X \to \mathcal{F} \) an \( \mathcal{O}_B \)-derivation. We may think of \( \mathcal{O}_X \) as the sheaf of “functions” on \( X \) and of \( \mathcal{O}_B \) as the sheaf of “constant functions.” For each integer \( i \geq 0 \), let \( T^i(\mathcal{F}) \) be the tensor product over \( \mathcal{O}_X \) of \( i \) copies of \( \mathcal{F} \), and denote by \( S^i(\mathcal{F}) \) and \( A^i(\mathcal{F}) \) its symmetric and exterior quotients. Let \( S(\mathcal{F}) \) be the direct product of all the \( S_i(\mathcal{F}) \) for all integers \( i \geq 0 \), with its natural graded \( \mathcal{O}_X \)-algebra structure. We may think of \( S(\mathcal{F}) \) as the sheaf of “formal power series” on the sections of \( \mathcal{F} \).

We define a \( D \)-connection to be a map of \( \mathcal{O}_B \)-modules \( \gamma: \mathcal{F} \to T^2(\mathcal{F}) \) satisfying

\[
\gamma(am) = D(a) \otimes m + a\gamma(m)
\]

for all local sections \( a \) of \( \mathcal{O}_X \) and \( m \) of \( \mathcal{F} \). We will see in Construction 2.5 how \( \gamma \) can be used to iterate \( D \) to obtain a sequence of maps \( T_i: \mathcal{F} \to S^i(\mathcal{F}) \otimes \mathcal{F} \), for \( i = 0, 1, \ldots \), where \( T_0 := \text{id}_\mathcal{F} \), \( T_1 = \gamma \), and the \( T_i \) satisfy properties similar to that of a connection, i.e. Equations 2.5.3 We call any sequence of maps \( T = (T_0, T_1, \ldots) \) with these properties, for any \( D \)-connection \( \gamma \), an extended \( D \)-connection.

From an extended \( D \)-connection \( T \) we get a map \( h: \mathcal{O}_X \to S(\mathcal{F}) \) of \( \mathcal{O}_B \)-algebras, with \( h_0 := \text{id}_{\mathcal{O}_X} \) and \( h_1 := D \), by letting \( h_i(a) \) be the class in \( S^i(\mathcal{F}) \) of \( (1/i)T_{i-1}D(a) \) for each local section \( a \) of \( \mathcal{O}_X \); see Construction 2.7. We may think of \( h \) as a way of computing “Taylor series” of functions on \( X \). In this way, \( S(\mathcal{F}) \) may be regarded as a sheaf of jets. We call such an \( h \) an iterated Hasse derivation.

However, \( D \)-connections are usually local gadgets. So, to be able to patch the local maps \( h \), we need \( D \)-connections to be canonical. But there is nothing canonical about \( \gamma \): for every \( \mathcal{O}_X \)-linear map \( \nu: \mathcal{F} \to T^2(\mathcal{F}) \), the sum \( \gamma + \nu \) is also a \( D \)-connection! So we study special \( D \)-connections.

A \( D \)-connection \( \gamma \) is called flat if the image of \( \gamma D(\mathcal{O}_X) \) in \( A^2(\mathcal{F}) \) is zero. When such \( \gamma \) exists, we say that \( D \) is integrable. Our main result, Theorem 4.1, shows that, given a flat \( D \)-connection \( \gamma \), there is an extended \( D \)-connection \( T \) with \( T_1 = \gamma \), which is also flat, meaning that \( T_iD(\mathcal{O}_X) \) lies in the subsheaf of \( S^i(\mathcal{F}) \otimes \mathcal{F} \) generated...
for each $q > 0$. \( \sum_{i=1}^{q} m_{1}m_{2} \cdots m_{i-1}m_{i+1}m_{i+2} \cdots m_{q} \otimes m_{i} \) for all local sections \( m_{1}, \ldots, m_{i} \) of \( F \), for each \( i \geq 1 \).

Now, our Proposition 3.5 says that a flat, extended \( D \)-connection is “comparable” to any other extended \( D \)-connection. So, Theorem 3.1 and Proposition 3.5 can be coupled to yield that all iterated Hasse derivations are equivalent; see Corollary 3.5. More precisely, if \( h \) and \( h' \) are iterated Hasse derivations, there is an \( O_{X} \)-algebra automorphism \( \phi : S(F) \to S(F) \) such that \( h' = \phi h \). Furthermore, the degree-\( i \) part of this \( \phi \) is zero if \( i < 0 \) and the identity if \( i = 0 \).

Now, for the patching we also need the automorphisms \( \phi \) to be canonical, so that cocycle conditions are satisfied. For this, we make a technical assumption on \( D \), that bounds its singularities, and holds in all applications we know of; see Corollary 4.3 and the remark thereafter.

Finally, assume that \( D \) is locally integrable, and has bounded singularities, in the sense alluded to above. The patching of the local iterated Hasse derivations and the \( O_{X} \)-algebra automorphisms comparing them is straightforward. We obtain an \( O_{X} \)-algebra \( J \) and a map \( h : O_{X} \to J \) of \( O_{B} \)-algebras. Also, since the local \( O_{X} \)-algebra automorphisms do not decrease degrees, and their degree-0 parts are the identity, \( J \) comes naturally with a filtration by \( O_{X} \)-algebra quotients \( J^{q} \), for \( q = 0, 1, \ldots \), and natural exact sequences

\[
0 \to S^{q}(F) \to J^{q} \to J^{q-1} \to 0
\]

for each \( q > 0 \); see Construction 4.4. We say that \( J^{q} \) is the sheaf of \( q \)-jets of \( D \).

How does this formal construction fit with the geometric setting? If \( M \) is a holomorphic manifold, let \( (X, O_{X}) \) be the ringed space where \( X \) is the underlying topological space of \( M \) and \( O_{X} \) is its sheaf of holomorphic functions. Let \( O_{B} \) be the sheaf of constant complex functions. A map of vector bundles \( w : T_{M} \to E \) corresponds to a derivation \( D : O_{X} \to F \), where \( F \) is the sheaf of holomorphic sections of \( E \). To say that \( w \) arises from a foliation on an open subset \( U \subseteq M \) is equivalent to say that \( F|_{U} = O_{U}D(O_{U}) \) and \( D|_{U} \) is locally integrable on \( U \); see Example 4.2. Now, assume that \( D \) is locally integrable on the whole \( X \), and that \( D(O_{X}) \) generates \( F \) as an \( O_{X} \)-module on a dense open subset \( M^{0} \subseteq M \). Then there exists a sheaf of \( q \)-jets \( J^{q} \) on \( X \), as explained above. Also, \( w \) defines a foliation \( L \) on \( M^{0} \), and \( J^{q}|_{M^{0}} \) is the sheaf of sections of the bundle of \( q \)-jets \( J^{q}_{L} \); see Example 4.3.

Bundles of jets associated to foliations or derivations were considered by a number of people. In algebraic geometry, to my knowledge, the first was Letterio Gatto, who in his thesis [6] constructed jets from a family of stable curves \( f : X \to S \) and its canonical derivation \( O_{X} \to \omega_{X/S} \), where \( \omega_{X/S} \) is the relative dualizing sheaf. Afterwards, in [1], jets were constructed for more general families, of local complete intersection curves, over any base and in any characteristic.

Also, Dan Laksov and Anders Thorup constructed bundles of jets in a series of articles in different setups; see [8], [9], and [10]. In characteristic zero, their more general work is [9]. Actually, in [9], Laksov and Thorup construct larger sheaves of “jets”, that are naturally noncommutative. The true generalization of the sheaf of jets is what they call “symmetric” jets. They show that the sheaf of (symmetric) jets is uniquely defined when \( F \) is free and has an \( O_{X} \)-basis under which \( D \) can be expressed using commuting derivations of \( O_{X} \). As we have observed above, the
uniqueness of the definition is important for patching. However, the commutativity is stronger than Frobenius’ conditions, at least in the algebraic category — in the analytic category, at nonsingular points, the local existence of commuting derivations follows from the existence of the foliation. The present work arose from the feeling that the Frobenius’ conditions should be enough to construct sheaves of jets.

There have already been applications of the sheaves of jets associated to a foliation or a derivation. They were used by Gatto [7], and Gatto and myself [3] in enumerative applications. They were used by myself in understanding limits of ramification points [2], and of Weierstrass points, with Nivaldo Medeiros, [4] and [5]. They were also used by Jorge Vitório Pereira in the study of foliations of the projective space [12].

Finally, we will see an example where the integrability condition holds and \( F \) is not locally free; see Example 3.3. That will be the example of the canonical derivation on a special non-Gorenstein curve, arguably the simplest non-Gorenstein unibranch curve there is, whose complete local ring at the singular point is of the form \( \mathbb{C}[[t^3, t^4, t^5]] \), as a subring of \( \mathbb{C}[[t]] \). It could be that the integrability condition holds for the canonical derivation on any curve, Gorenstein or not. If so, the sheaf of jets might be used to define Weierstrass points on non-Gorenstein integral curves, and show that these points are limits of Weierstrass points on nearby curves, in the way done by Robert Lax and Carl Widland for Gorenstein curves; see [11] and [13]. However, this problem will not be pursued here.

Here is a layout of the article. In Section 2, we define connections, extended connections and iterated Hasse derivations, and explain a few preliminary constructions. In Section 3, we define integrable derivations and flat (extended) connections, and show that a flat, extended connection is comparable with any other extended connection. Finally, in Section 4, we show that, if a derivation \( D \) is integrable, then flat, extended connections exist, and all iterated Hasse derivations are equivalent; then we construct the sheaves of jets for locally integrable derivations.

This work started as a joint work with Letterio Gatto. However, he felt he did not contribute to it as much as he wished. Though a few discussions with him were vital to how this work came to be, and though I feel that this could be classified as a joint work, I had to respect his decision to not coauthor it. Anyway, being the only thing left for me to do, I thank him for his great contributions.

2. Derivations and connections

**Construction 2.1.** (Tensor operations) Let \( X \) be a topological space and \( \mathcal{O}_X \) a sheaf of \( \mathbb{Q} \)-algebras. Let \( \mathcal{F} \) be a sheaf of \( \mathcal{O}_X \)-modules. Denote by

\[
\mathcal{T}(\mathcal{F}) := \prod_{n=0}^{\infty} T^n(\mathcal{F}), \quad \mathcal{S}(\mathcal{F}) := \prod_{n=0}^{\infty} S^n(\mathcal{F}), \quad \mathcal{A}(\mathcal{F}) := \prod_{n=0}^{\infty} A^n(\mathcal{F})
\]

the formal tensor, symmetric and exterior graded sheaf of \( \mathcal{O}_X \)-algebras of \( \mathcal{F} \), respectively. (Note that we take the direct product and not the direct sum.)

Set \( \mathcal{R}^0(\mathcal{F}) := \mathcal{O}_X \). Also, set \( \mathcal{R}^n(\mathcal{F}) := S^{n-1}(\mathcal{F}) \otimes \mathcal{F} \) for each integer \( n \geq 1 \), and

\[
\mathcal{R}(\mathcal{F}) := \prod_{n=0}^{\infty} \mathcal{R}^n(\mathcal{F}).
\]

Then \( \mathcal{R}(\mathcal{F}) \) is a graded \( \mathcal{O}_X \)-algebra quotient of \( \mathcal{T}(\mathcal{F}) \), in a natural way.
As usual, we let $\mathcal{T}_+ (\mathcal{F})$, $\mathcal{S}_+ (\mathcal{F})$, $\mathcal{A}_+ (\mathcal{F})$ and $\mathcal{R}_+ (\mathcal{F})$ denote the ideals generated by formal sums with zero constant terms in each of the indicated $\mathcal{O}_X$-algebras.

We view $\mathcal{T}(\mathcal{F})$ as a sheaf of algebras, with the (noncommutative) product induced by tensor product. So, given local sections $m_1, \ldots, m_n$ of $\mathcal{F}$, we let $m_1 \cdots m_n$ denote their product in $\mathcal{T}^n(\mathcal{F})$. Also, we view $\mathcal{S}(\mathcal{F})$, $\mathcal{A}(\mathcal{F})$ and $\mathcal{R}(\mathcal{F})$ as sheaves of $\mathcal{T}(\mathcal{F})$-algebras, and $\mathcal{S}(\mathcal{F})$ as a sheaf of $\mathcal{R}(\mathcal{F})$-algebras, under the natural quotient maps. So, given a local section $\omega$ of $\mathcal{T}^n(\mathcal{F})$ (resp. $\mathcal{R}^n(\mathcal{F})$), we will use the same symbol $\omega$ to denote its image in $\mathcal{S}^n(\mathcal{F})$, $\mathcal{A}^n(\mathcal{F})$ or $\mathcal{R}^n(\mathcal{F})$ (resp. $\mathcal{S}(\mathcal{F})$). These simplifications should not lead to confusion, and will clean the notation enormously.

Define the switch operator $\sigma: \mathcal{R}_+ (\mathcal{F}) \to \mathcal{R}_+ (\mathcal{F})$ as the homogeneous $\mathcal{O}_X$-linear map of degree 0 given by $\sigma |_{\mathcal{F}} := 0$, and on each $\mathcal{R}^n(\mathcal{F})$, for $n \geq 2$, by the formula:

$$
\sigma (m_1 \cdots m_n) = \sum_{i=1}^{n-1} m_n m_{n-1} \cdots m_{n-i+2} m_{n-i+1} m_1 m_2 \cdots m_{n-i-1} m_{n-i}
$$

for all local sections $m_1, \ldots, m_n$ of $\mathcal{F}$. The reader may check that $\sigma$ is actually well-defined on $\mathcal{R}_+ (\mathcal{F})$, and not only on $\mathcal{T}_+ (\mathcal{F})$.

Let $\sigma^* := 1 + \sigma$. Notice that $\sigma^*$ factors through $\mathcal{S}_+ (\mathcal{F})$. For each integer $n \geq 1$, let $\mathcal{K}^n (\mathcal{F}) := \sigma^*(\mathcal{R}^n(\mathcal{F}))$. Then $\mathcal{K}^n (\mathcal{F})$ is also the kernel of $n - \sigma^*$. In particular, $\mathcal{K}^2 (\mathcal{F})$ is the kernel of the surjection $\mathcal{T}^2(\mathcal{F}) \to \mathcal{A}^2(\mathcal{F})$. Indeed, that $\mathcal{K}^n (\mathcal{F})$ is in the kernel of $n - \sigma^*$ follows from the equality

$$
\sigma^* |_{\mathcal{R}^n(\mathcal{F})} = n\sigma^* |_{\mathcal{R}^n(\mathcal{F})},
$$

a fact checked locally. And if $\omega$ is a local section of $\mathcal{R}^n(\mathcal{F})$ such that $(n - \sigma^*)(\omega) = 0$, then $\omega = \sigma^*((1/n)\omega)$, and thus $\omega$ is a local section of $\mathcal{K}^n (\mathcal{F})$.

Put

$$
\mathcal{K}_+ (\mathcal{F}) := \prod_{n=1}^{\infty} \mathcal{K}^n (\mathcal{F}).
$$

**Definition 2.2.** Let $X$ be a topological space, $\mathcal{O}_B$ a sheaf of $\mathcal{Q}$-algebras and $\mathcal{O}_X$ a sheaf of $\mathcal{O}_B$-algebras. Let $\mathcal{F}$ be a sheaf of $\mathcal{O}_X$-modules. A Hasse derivation of $\mathcal{F}$ is a map of $\mathcal{O}_B$-algebras

$$
h = (h_0, h_1, \ldots): \mathcal{O}_X \to \prod_{i=0}^{\infty} \mathcal{S}^i(\mathcal{F})
$$

with $h_0 = \text{id}_{\mathcal{O}_X}$. Let $D: \mathcal{O}_X \to \mathcal{F}$ be an $\mathcal{O}_B$-derivation. We say that $h$ extends $D$ if $h_1 = D$.

If $h = (h_0, h_1, \ldots)$ is a Hasse derivation of $\mathcal{F}$, then $h_1: \mathcal{O}_X \to \mathcal{F}$ is an $\mathcal{O}_B$-derivation of $\mathcal{F}$. Conversely, given an $\mathcal{O}_B$-derivation $D: \mathcal{O}_X \to \mathcal{F}$, we may ask when there is a Hasse derivation $h = (h_0, h_1, \ldots)$ of $\mathcal{F}$ extending $D$. We will see in Construction 2.27 that such $h$ exists when there is a $D$-connection.

**Definition 2.3.** Let $X$ be a topological space, $\mathcal{O}_B$ a sheaf of $\mathcal{Q}$-algebras and $\mathcal{O}_X$ a sheaf of $\mathcal{O}_B$-algebras. Let $\mathcal{F}$ be a sheaf of $\mathcal{O}_X$-modules and $D: \mathcal{O}_X \to \mathcal{F}$ an $\mathcal{O}_B$-derivation. A $D$-connection is a map of $\mathcal{O}_B$-modules

$$
\gamma: \mathcal{F} \to \mathcal{T}^2(\mathcal{F})
$$

satisfying

$$
\gamma(am) = D(a)m + a\gamma(m)
$$

for each local sections $a$ of $\mathcal{O}_X$ and $m$ of $\mathcal{F}$. 
Example 2.4. There may not exist a $D$-connection. For instance, let $X$ be the union of two transversal lines in the plane, or $X := \text{Spec}(\mathbb{C}[x,y]/(xy))$. Let $\Omega^1_X$ be the sheaf of differentials, and $D : \mathcal{O}_X \to \Omega^1_X$ the universal $\mathbb{C}$-derivation. The sheaf $\Omega^1_X$ is generated by $D(x)$ and $D(y)$, and the sheaf of relations is generated by the single relation $yD(x) + xD(y) = 0$. In particular, $D(x)$ and $D(y)$ are $\mathbb{C}$-linearly independent at the node. Suppose there were a $D$-connection $\gamma : \Omega^1_X \to \mathcal{T}^2(\Omega^1_X)$. Then
\[
0 = \gamma(yD(x) + xD(y)) = D(y)D(x) + D(x)D(y) + y\gamma(D(x)) + x\gamma(D(y)).
\]
However, $D(x)D(x)$, $D(x)D(y)$, $D(y)D(x)$ and $D(y)D(y)$ are linearly independent sections of $\mathcal{T}^2(\Omega^1_X)$ at the node. Hence the above relation is not possible.

When a $D$-connection $\gamma$ exists, it is not unique, since for every $\mathcal{O}_X$-linear map $\lambda : \mathcal{F} \to \mathcal{T}^2(\mathcal{F})$, the sum $\gamma + \lambda$ is a $D$-connection. However, these are all the $D$-connections.

A $D$-connection allows us to iterate $D$ to a Hasse derivation, as we will explain in Construction 2.5. First, we will see how to extend a connection.

Construction 2.5. (Extending connections) Let $X$ be a topological space, $\mathcal{O}_B$ a sheaf of $\mathbb{Q}$-algebras and $\mathcal{O}_X$ a sheaf of $\mathcal{O}_B$-algebras. Let $\mathcal{F}$ be a sheaf of $\mathcal{O}_X$-modules and $D : \mathcal{O}_X \to \mathcal{F}$ an $\mathcal{O}_B$-derivation. Let $\gamma : \mathcal{F} \to \mathcal{T}^2(\mathcal{F})$ be a $D$-connection. Define a homogeneous map of degree 1 of $\mathcal{O}_B$-modules,
\[
\nabla : \mathcal{R}_+(\mathcal{F}) \to \mathcal{R}_+(\mathcal{F}),
\]
given on each graded part $\mathcal{R}^n(\mathcal{F})$ by
\[
\nabla(m_1 \cdots m_n) := \sum_{i=1}^n m_1 \cdots m_{i-1}\gamma(m_i)m_{i+1} \cdots m_n
\]
for each local sections $m_1, \ldots, m_n$ of $\mathcal{F}$.

At first, it seems $\nabla$ would be a well-defined map from $\mathcal{T}_+(\mathcal{F})$ to $\mathcal{T}_+(\mathcal{F})$. This would indeed be true, were $\gamma$ a map of $\mathcal{O}_X$-modules. But $\gamma$ is not! To check that $\nabla$, as given above, is well-defined, we need to check the following three properties for all local sections $m_1, \ldots, m_i, m'_i, \ldots, m'_n$ of $\mathcal{F}$ and $a$ of $\mathcal{O}_X$, and each permutation $\tau$ of $\{1, \ldots, n-1\}$:

1. For each $i = 1, \ldots, n$,
\[
\nabla(m_1 \cdots m_i + m'_i \cdots m_n) = \nabla(m_1 \cdots m_i \cdots m_n) + \nabla(m_1 \cdots m'_i \cdots m_n).
\]
2. For each $i, j = 1, \ldots, n$,
\[
\nabla(m_1 \cdots (am_i) \cdots m_n) = \nabla(m_1 \cdots (am_j) \cdots m_n).
\]
3. $\nabla(m_1 \cdots m_{n-1}m_n) = \nabla(m_{\tau(1)} \cdots m_{\tau(n-1)}m_n)$.

The first (multilinearity) and third (symmetry) properties are left for the reader to check. The second property is the key to why $\nabla$ must take values in $\mathcal{R}_+(\mathcal{F})$, so let us check it: from the definition of $\nabla$, and using $\gamma(am_i) = D(a)m_i + a\gamma(m_i)$, we get
\[
\nabla(m_1 \cdots (am_i) \cdots m_n) = m_1 \cdots m_{i-1}D(a)m_i \cdots m_n + a\sum_{j=1}^n m_1 \cdots \gamma(m_j) \cdots m_n.
\]

So $\nabla(m_1 \cdots (am_i) \cdots m_n)$ would depend on $i$, were $\nabla$ to take values in $\mathcal{T}_+(\mathcal{F})$. But instead, $\nabla$ takes values in $\mathcal{R}_+(\mathcal{F})$, and hence
\[
m_1 \cdots m_{i-1}D(a)m_i \cdots m_n = D(a)m_1 \cdots m_{i-1}m_i \cdots m_n.
\]
So the second property (scalar multiplication) is checked, and the three properties imply that $\nabla$ is well-defined. Also, we proved the formula
\[ \nabla(a\omega) = D(a)\omega + a\nabla(\omega) \]
for all local sections $\omega$ of $\mathcal{R}_+(\mathcal{F})$ and $a$ of $\mathcal{O}_X$.

Now, for each integer $n \geq 1$, put
\[ T_n := \frac{1}{n!}\nabla^n|_F : \mathcal{F} \to \mathcal{R}^{n+1}(\mathcal{F}). \]

Also, set $T_0 := \text{id}_F$. Then $T_n = (1/n)\nabla T_{n-1}$ for each $n \geq 1$. Furthermore, for each integer $i \geq 1$, and each local sections $a$ of $\mathcal{O}_X$ and $m$ of $\mathcal{F}$,

\[ T_i(am) = aT_i(m) + \sum_{j=1}^{i} \frac{1}{j} T_{j-1}D(a)T_{i-j}(m). \tag{2.5.3} \]

Indeed, Formula (2.5.3) holds for $i = 1$, because $T_1 = \gamma$ and $\gamma$ is a $D$-connection. And if, by induction, Formula (2.5.3) holds for a certain $i \geq 1$, then

\[
T_{i+1}(am) = \frac{1}{(i + 1)} \nabla T_i(am) \\
= \frac{1}{(i + 1)} \nabla \left( aT_i(m) + \sum_{j=1}^{i} \frac{1}{j} T_{j-1}D(a)T_{i-j}(m) \right) \\
= \frac{1}{(i + 1)} \left( a\nabla T_i(m) + D(a)T_i(m) \right) \\
+ \frac{1}{(i + 1)} \sum_{j=1}^{i} \frac{1}{j} \left( \nabla T_{j-1}D(a)T_{i-j}(m) + T_{j-1}D(a)\nabla T_{i-j}(m) \right) \\
= aT_{i+1}(m) + \frac{1}{(i + 1)} D(a)T_i(m) \\
+ \frac{1}{(i + 1)} \sum_{j=1}^{i} \left( \frac{1}{j} T_{j-1}D(a)T_{i-j}(m) + \frac{i + 1 - j}{j} T_{j-1}D(a)T_{i+1-j}(m) \right) \\
= aT_{i+1}(m) + \frac{1}{(i + 1)} D(a)T_i(m) \\
+ \sum_{j=2}^{i} \left( \frac{1}{j} T_{j-1}D(a)T_{i+1-j}(m) \right) + \frac{1}{(i + 1)} T_iD(a)m + \frac{i}{(i + 1)} D(a)T_i(m) \\
= aT_{i+1}(m) + \sum_{j=1}^{i+1} \frac{1}{j} T_{j-1}D(a)T_{i+1-j}(m). \\
\]

The maps $T_n$ form an extended $D$-connection, according to the definition below.

**Definition 2.6.** Let $X$ be a topological space, $\mathcal{O}_B$ a sheaf of $\mathcal{Q}$-algebras and $\mathcal{O}_X$ a sheaf of $\mathcal{O}_B$-algebras. Let $\mathcal{F}$ be a sheaf of $\mathcal{O}_X$-modules and $D : \mathcal{O}_X \rightarrow \mathcal{F}$ an $\mathcal{O}_B$-derivation. Let $n$ be a positive integer or $n := \infty$. A map of $\mathcal{O}_B$-modules

\[ T = (T_0, T_1, T_2, \ldots) : \mathcal{F} \rightarrow \prod_{i=0}^{n} \mathcal{R}^{i+1}(\mathcal{F}) \]
We say that an extended $D$-connection if $T_0 = \text{id}_F$ and Formula [2.5.3] holds for each $i \geq 1$ and all local sections $a$ of $\mathcal{O}_X$ and $m$ of $\mathcal{F}$.

If nothing is noted otherwise, extended $D$-connections are assumed full, that is, with $n := \infty$.

**Construction 2.7.** (Hasse derivations arising from $D$-connections) Let $X$ be a topological space, $\mathcal{O}_B$ a sheaf of $\mathbb{Q}$-algebras and $\mathcal{O}_X$ a sheaf of $\mathcal{O}_B$-algebras. Let $\mathcal{F}$ be a sheaf of $\mathcal{O}_X$-modules, $D: \mathcal{O}_X \to \mathcal{F}$ an $\mathcal{O}_B$-derivation and $T: \mathcal{F} \to \mathcal{R}_+(\mathcal{F})$ an extended $D$-connection. Notice that the map $T_1: \mathcal{F} \to \mathcal{F} \otimes \mathcal{F}$ is a $D$-connection. However, $T$ need not arise from $T_1$ as in Construction 2.5.

Put $h_0 := \text{id}_\mathcal{O}_X$, and for each integer $i \geq 1$ let $h_i: \mathcal{O}_X \to S^i(\mathcal{F})$ be the $\mathcal{O}_B$-linear map given by $h_i(a) := \left(1/i\right)T_{i-1}D(a)$ for each local section $a$ of $\mathcal{O}_X$. Then

$$h := (h_0, h_1, h_2, \ldots): \mathcal{O}_X \to \prod_{i=0}^{\infty} S^i(\mathcal{F})$$

is a Hasse derivation of $\mathcal{F}$ extending $D$. Indeed, clearly $h_1 = D$. Now, if $a$ and $b$ are local sections of $\mathcal{O}_X$, and $i \geq 1$, then

$$h_i(ab) = \frac{1}{i}T_{i-1}\left(aD(b) + bD(a)\right)$$

$$= \frac{1}{i}\left(aT_{i-1}D(b) + \sum_{j=1}^{i-1} \frac{1}{j}T_{j-1}D(a)T_{i-1-j}D(b)\right)$$

$$+ \frac{1}{i}\left(bT_{i-1}D(a) + \sum_{j=1}^{i-1} \frac{1}{j}T_{j-1}D(b)T_{i-1-j}D(a)\right)$$

$$= ah_i(b) + bh_i(a)$$

$$+ \frac{1}{i}\sum_{j=1}^{i-1} \left(\frac{1}{j}T_{j-1}D(a)T_{i-1-j}D(b) + \frac{1}{i-j}T_{i-1-j}D(b)T_{j-1}D(a)\right)$$

$$= ah_i(b) + bh_i(a) + \sum_{j=1}^{i-1} \left(\frac{1}{j(i-j)}T_{j-1}D(a)T_{i-1-j}D(b)\right)$$

$$= \sum_{j=0}^{i} h_j(a)h_{i-j}(b),$$

where in the fourth equality we used that the computation is done in $S^i(\mathcal{F})$.

**Definition 2.8.** Let $X$ be a topological space, $\mathcal{O}_B$ a sheaf of $\mathbb{Q}$-algebras and $\mathcal{O}_X$ a sheaf of $\mathcal{O}_B$-algebras. Let $\mathcal{F}$ be a sheaf of $\mathcal{O}_X$-modules, $D: \mathcal{O}_X \to \mathcal{F}$ an $\mathcal{O}_B$-derivation and $h$ a Hasse derivation extending $D$. We say that $h$ is iterated if there is an extended $D$-connection $T$ such that $h_i = (1/i)T_{i-1}D$ for each $i \geq 1$.

3. Flat connections and integrable derivations

**Definition 3.1.** Let $X$ be a topological space, $\mathcal{O}_B$ a sheaf of $\mathbb{Q}$-algebras and $\mathcal{O}_X$ a sheaf of $\mathcal{O}_B$-algebras. Let $\mathcal{F}$ be a sheaf of $\mathcal{O}_X$-modules and $D: \mathcal{O}_X \to \mathcal{F}$ an $\mathcal{O}_B$-derivation. We say that a $D$-connection $\gamma: \mathcal{F} \to T^2(\mathcal{F})$ is flat if $\gamma D(\mathcal{O}_X) \subseteq \mathcal{K}^2(\mathcal{F})$. We say that $D$ is integrable if there exists a flat $D$-connection.
Example 3.2. Let $X$ be a topological space, $\mathcal{O}_B$ a sheaf of $\mathbb{Q}$-algebras and $\mathcal{O}_X$ a sheaf of $\mathcal{O}_B$-algebras. Let $\mathcal{F}$ be the free sheaf of $\mathcal{O}_X$-modules with basis $e_1, \ldots, e_n$. Let $D: \mathcal{O}_X \to \mathcal{F}$ be an $\mathcal{O}_B$-derivation. Then $D = D_1 e_1 + \cdots + D_n e_n$, where the $D_i$ are $\mathcal{O}_B$-derivations of $\mathcal{O}_X$. Conversely, a $n$-tuple $(D_1, \ldots, D_n)$ of $\mathcal{O}_B$-derivations of $\mathcal{O}_X$ defines an $\mathcal{O}_B$-derivation of $\mathcal{F}$.

There is a natural $D$-connection $\gamma: \mathcal{F} \to T^2(\mathcal{F})$, satisfying

$$\gamma(\sum_{i=1}^n a_i e_i) = \sum_{i=1}^n \sum_{j=1}^n D_{ij}(a_i) e_j e_i$$

for all local sections $a_1, \ldots, a_n$ of $\mathcal{O}_X$. Any other $D$-connection is of the form $\gamma + \nu$, where $\nu: \mathcal{F} \to T^2(\mathcal{F})$ is a map of $\mathcal{O}_X$-modules. The map $\nu$ is defined by global sections $c_{i,j}^\ell$ of $\mathcal{O}_X$, for $1 \leq i, j, \ell \leq n$, satisfying

$$\nu(e_\ell) = \sum_{i=1}^n \sum_{j=1}^n c_{i,j}^\ell e_j e_i.$$ 

To say that $(\gamma + \nu)D(a) = 0$ in $\mathcal{A}^2(\mathcal{F})$ for a local section $a$ of $\mathcal{O}_X$ is to say that

$$\sum_{i=1}^n \sum_{j=1}^n D_{ij}D_\ell(a)e_j e_i + \sum_{\ell=1}^n \sum_{i=1}^n \sum_{j=1}^n c_{i,j}^\ell D_{ij}(a)e_j e_i = 0$$

in $\mathcal{A}^2(\mathcal{F})$ or, equivalently,

$$D_j D_\ell(a) - D_\ell D_j(a) = \sum_{\ell=1}^n (c_{i,j}^\ell - c_{j,i}^\ell) D_\ell(a)$$

for all distinct $i$ and $j$. In other words, $D$ is integrable if and only if the collection $\{D_1, \ldots, D_n\}$ is involutive, i.e., if and only if there are sections $b_{i,j}^\ell$ of $\mathcal{O}_X$ such that

$$[D_j, D_\ell] = \sum_{\ell=1}^n b_{i,j}^\ell D_\ell$$

for all distinct $i$ and $j$.

Let $T$ be the extended $D$-connection of Construction 2.2 derived from $\gamma$. From the definition of $\gamma$ we have $T_q(e_i) = 0$ for each integer $q > 0$ and each $i = 1, \ldots, n$. Suppose $\gamma D = 0$ in $\mathcal{A}^2(\mathcal{F})$, or in other words $[D_j, D_\ell] = 0$ for all $i$ and $j$. Then the Hasse derivation $h$ associated to $T$ satisfies

$$h_q(a) = \sum_{j_1=1}^n \sum_{j_2=1}^n \cdots \frac{D_{j_1} \cdots D_{j_q}(a)}{q!} e_{j_1} \cdots e_{j_q}$$

for each integer $q > 0$ and each local section $a$ of $\mathcal{F}$.

Example 3.3. It is not necessary that $\mathcal{F}$ be locally free for a flat $D$-connection to exist. For instance, let $X := \text{Spec}(\mathbb{C}[t^3, t^4, t^5])$. Viewed as a sheaf of regular meromorphic differentials, Rosenlicht-style, the dualizing sheaf $\omega_X$ is generated by $dt/t^2$ and $dt/t^3$. Let $\eta_1 := dt/t^2$ and $\eta_2 := dt/t^3$. The following relations generate all relations $\eta_1$ and $\eta_2$ satisfy with coefficients in $\mathcal{O}_X$:

$$(3.3.1) \quad t^3 \eta_1 = t^4 \eta_2, \quad t^4 \eta_1 = t^5 \eta_2, \quad t^5 \eta_1 = t^6 \eta_2.$$ 

The composition of the universal derivation with the canonical map $\Omega^1_X \to \omega_X$ yields a derivation $D: \mathcal{O}_X \to \omega_X$ satisfying

$$D(t^3) = 3t^4 \eta_1 = 3t^5 \eta_2, \quad D(t^4) = 4t^5 \eta_1 = 4t^6 \eta_2, \quad D(t^5) = 5t^6 \eta_1 = 5t^7 \eta_2.$$
So \( D(a)\eta_1 = 0 \) in \( \mathcal{A}^2(\omega_X) \) for each local section \( a \) of \( \mathcal{O}_X \) and each \( i = 1, 2 \).

Define \( \gamma: \omega_X \to \mathcal{T}^2(\omega_X) \) by letting

\[
\gamma(a\eta_1 + b\eta_2) = D(a)\eta_1 + D(b)\eta_2 + 4t^3a\eta_2 + 3b\eta_1\eta_1
\]

for all local sections \( a \) and \( b \) of \( \mathcal{O}_X \). To check that \( \gamma \) is well defined we need only check that the values of \( \gamma \) on both sides of the three relations \((3.5.1)\) agree. This is the case; for instance,

\[
\gamma(t^3\eta_1) = 3t^4\eta_1 + 4t^6\eta_2 = 7t^4\eta_1\eta_1 = 4t^5\eta_1\eta_2 + 3t^4\eta_1\eta_1 = \gamma(t^4\eta_2).
\]

Now, since \( D(a)\eta_1 = D(b)\eta_2 = 0 \) in \( \mathcal{A}^2(\omega_X) \), we have that \( \gamma = 0 \) in \( \mathcal{A}^2(\omega_X) \). So \( \gamma \) is a flat \( D \)-connection, and hence \( D \) is integrable.

**Definition 3.4.** Let \( X \) be a topological space, \( \mathcal{O}_B \) a sheaf of \( \mathcal{Q} \)-algebras and \( \mathcal{O}_X \) a sheaf of \( \mathcal{O}_B \)-algebras. Let \( \mathcal{F} \) be a sheaf of \( \mathcal{O}_X \)-modules, and let \( D: \mathcal{O}_X \to \mathcal{F} \) be an \( \mathcal{O}_B \)-derivation. An extended \( D \)-connection \( T: \mathcal{F} \to \mathcal{R}^+(\mathcal{F}) \) is called flat if \( TD(\mathcal{O}_X) \subseteq \mathcal{K}_+(\mathcal{F}) \).

We will see in Theorem \[\text{[4.1]}\] that flat extended \( D \)-connections exist, when \( D \) is integrable. Also, by Proposition \[\text{[3.6]}\] below, any two of them are “comparable”.

First, a piece of notation.

**Construction 3.5.** (Generating maps) Let \( X \) be a topological space, \( \mathcal{O}_X \) a sheaf of \( \mathcal{Q} \)-algebras and \( \mathcal{F} \) a sheaf of \( \mathcal{O}_X \)-modules. Let \( n \) be a positive integer or \( n := \infty \).

Let

\[
\lambda = (\lambda_0, \lambda_1, \ldots) : \mathcal{F} \to \prod_{i=0}^{n} \mathcal{R}^{i+1}(\mathcal{F})
\]

be a map of \( \mathcal{O}_X \)-modules. For each integer \( p > 0 \) and each sequence \( i_1, \ldots, i_p \) of nonnegative indices at most equal to \( n \), let \( q := i_1 + \cdots + i_p \) and define

\[
(\lambda_{i_1} \cdots \lambda_{i_p}) : \mathcal{T}^p(\mathcal{F}) \to \mathcal{R}^{p+q}(\mathcal{F})
\]

to be the map of \( \mathcal{O}_X \)-modules satisfying

\[
(\lambda_{i_1} \cdots \lambda_{i_p})(m_1 \cdots m_p) := \lambda_{i_1}(m_1) \cdots \lambda_{i_p}(m_p)
\]

for all local sections \( m_1, \ldots, m_p \) of \( \mathcal{F} \).

The maps \( (\lambda_{i_1} \cdots \lambda_{i_p}) \) are not defined on \( \mathcal{R}^p(\mathcal{F}) \), but the sum

\[
s_q(\lambda) := \sum_{i_1 + \cdots + i_p = q} (i_p + 1)(\lambda_{i_1} \cdots \lambda_{i_p}) : \mathcal{R}^p(\mathcal{F}) \to \mathcal{R}^{p+q}(\mathcal{F})
\]

is, for all integers \( p > 0 \) and each integer \( q \) with \( 0 \leq q \leq n \). Analogously, the sum

\[
\tilde{s}_q(\lambda) := \sum_{i_1 + \cdots + i_p = q} (\lambda_{i_1} \cdots \lambda_{i_p}) : \mathcal{S}^p(\mathcal{F}) \to \mathcal{S}^{p+q}(\mathcal{F})
\]

is well-defined, for all integers \( p > 0 \) and each integer \( q \) with \( 0 \leq q \leq n \).

Notice that, for each local section \( \omega \) of \( \mathcal{K}^p(\mathcal{F}) \),

\[
(3.5.1) \quad s_q(\lambda)(\omega) = \frac{p + q}{p} \tilde{s}_q(\lambda)(\omega) \in \mathcal{S}^{p+q}(\mathcal{F}).
\]

Indeed, locally,

\[
\omega = \sum_{i=1}^{p} m_1 \cdots \hat{m}_i \cdots m_p m_i
\]
for local sections $m_1, \ldots, m_p$ of $F$. Thus, in $S^{p+q}(F)$,

$$s_q(\lambda)(\omega) = \sum_{i=1}^{p} \sum_{j_1+\cdots+j_p=q} (j_p + 1) \prod_{s=1}^{p-1} \lambda_{j_s}(m_s) \prod_{s=i}^{p} \lambda_{j_p}(m_{s+1}) \lambda_{j_p}(m_i)$$

$$= \sum_{j_1+\cdots+j_p=q} (j_i + 1) \prod_{s=1}^{p} \lambda_{j_s}(m_s)$$

$$= (p + q) \sum_{j_1+\cdots+j_p=q} \prod_{s=1}^{p} \lambda_{j_s}(m_s)$$

$$= \frac{p + q}{p} \sum_{j_1+\cdots+j_p=q} \sum_{i=1}^{p-1} \prod_{s=1}^{p} \lambda_{j_s}(m_s) \prod_{s=i}^{p} \lambda_{j_p}(m_{s+1}) \lambda_{j_p}(m_i)$$

$$= \frac{p + q}{p} \sum_{j_1+\cdots+j_p=q} (\lambda_{j_1} \cdots \lambda_{j_p})(\omega)$$

$$= \frac{p + q}{p} \tilde{s}_q(\lambda)(\omega).$$

**Proposition 3.6.** Let $X$ be a topological space, $\mathcal{O}_B$ a sheaf of $\mathbb{Q}$-algebras and $\mathcal{O}_X$ a sheaf of $\mathcal{O}_B$-algebras. Let $\mathcal{F}$ be a sheaf of $\mathcal{O}_X$-modules and $D: \mathcal{O}_X \to \mathcal{F}$ an $\mathcal{O}_B$-derivation. Let $n$ be a positive integer. Let

$$T = (T_0, T_1, \ldots, T_n): \mathcal{F} \to \prod_{i=0}^{n} \mathcal{R}^{i+1}(\mathcal{F})$$

$$S = (S_0, S_1, \ldots, S_n): \mathcal{F} \to \prod_{i=0}^{n} \mathcal{R}^{i+1}(\mathcal{F})$$

be two $\mathcal{O}_B$-linear maps. Assume that $T_i D(\mathcal{O}_X) \subseteq K^{i+1}(\mathcal{F})$ for each $i = 0, \ldots, n-1$. Then any two of the following three statements imply the third:

1. The map $S$ is an extended $D$-connection.
2. The map $T$ is an extended $D$-connection.
3. There is a (unique) map of $\mathcal{O}_X$-modules

$$\lambda = (\lambda_0, \ldots, \lambda_n): \mathcal{F} \to \prod_{i=0}^{n} \mathcal{R}^{i+1}(\mathcal{F})$$

such that $\lambda_0 = \text{id}_\mathcal{F}$ and

$$(3.6.1) \quad S_i = \sum_{\ell=0}^{i} s_{i-\ell}(\lambda) T_\ell$$

for each $i = 0, 1, \ldots, n$.

**Proof.** We will argue by induction. For $n = 1$, the proposition simply says that, given a $D$-connection $T_1$, a map of $\mathcal{O}_B$-modules $S_1: \mathcal{F} \to \mathcal{R}^2(\mathcal{F})$ is a $D$-connection if and only if $S_1 - T_1$ is $\mathcal{O}_X$-linear, a fact already observed.

Suppose now that $n \geq 2$, and that the statement of the proposition is known for $n - 1$ in place of $n$. So we may assume that $(S_0, \ldots, S_{n-1})$ and $(T_0, \ldots, T_{n-1})$ are
extended $D$-connections, and that there exists a map of $\mathcal{O}_X$-modules

$$\lambda = (\lambda_0, \ldots, \lambda_{n-1}) : \mathcal{F} \to \prod_{i=0}^{n-1} \mathcal{R}^{i+1}(\mathcal{F})$$

such that $\lambda_0 = \text{id}_\mathcal{F}$ and Equations (3.6.1) hold for each $i < n$.

Define

$$R_n := \sum_{\ell=1}^{n-1} s_{n-\ell}(\lambda) T_\ell.$$

We need only show that, for each local sections $S$ of $\mathcal{O}_X$ and $m$ of $\mathcal{F}$,

$$R_n(\alpha m) - aR_n(m) + \sum_{z=0}^{n-1} \frac{T_{n-z-1}D(a)}{n-n} T_z(m) = \sum_{z=0}^{n-1} \frac{S_{n-z-1}D(a)}{n-n} S_z(m).$$

Indeed, if $S$ and $T$ are $D$-connections, Formula (3.6.2) implies that $S_n - R_n - T_n$ is $\mathcal{O}_X$-linear. So, setting $\lambda_n := (1/(n+1))(S_n - R_n - T_n)$, Equation (3.6.1) holds for $i = n$ as well. Conversely, if there is an $\mathcal{O}_X$-linear map $\lambda_n : \mathcal{F} \to \mathcal{R}^{n+1}(\mathcal{F})$ such that Equation (3.6.1) holds for $i = n$, then $(n+1)\lambda_n + R_n = S_n - T_n$. So, from Formula (3.6.2) we see that $S$ is a $D$-connection if and only if $T$ is.

Now, on the one hand, since $(T_0, \ldots, T_{n-1})$ is an extended $D$-connection,

$$R_n(\alpha m) - aR_n(m) = \sum_{\ell=1}^{n-1} \sum_{j_0+\cdots+j_\ell = n-\ell}^{n-1} (j_\ell + 1)(\lambda_{j_0} \cdots \lambda_{j_\ell}) \left( T_\ell(\alpha m) - aT_\ell(m) \right)$$

$$= \sum_{\ell=1}^{n-1} \sum_{\ell=1}^{n-1} \sum_{\ell=1}^{n-1} j_\ell + 1 \left( \lambda_{j_0} \cdots \lambda_{j_\ell} \right) \left( T_{\ell-1-p}D(a)T_p(m) \right).$$

Thus the left-hand side of Formula (3.6.2) is equal to

$$(3.6.3) \sum_{\ell=1}^{n-1} \sum_{\ell=1}^{n-1} \sum_{\ell=1}^{n-1} j_\ell + 1 \left( \lambda_{j_0} \cdots \lambda_{j_\ell} \right) \left( T_{\ell-1-p}D(a)T_p(m) \right).$$

On the other hand, using Equations (3.6.1) for $i < n$, the right-hand side of (3.6.2) becomes

$$\sum_{z=0}^{n-1} \frac{1}{n-z} \left( \sum_{k=0}^{n-z-1} \sum_{j_0+\cdots+j_k = n-z-1-k} (j_k + 1)(\lambda_{j_0} \cdots \lambda_{j_k}) T_k D(a) \right) \left( \sum_{p=0}^{z} \omega_{z-p} \right),$$

where

$$\omega_{\ell} := \sum_{j_0+\cdots+j_\ell = \ell} \left( j_\ell' + 1 \right)(\lambda_{j_0} \cdots \lambda_{j_\ell'}) T_p(m)$$

for each $\ell = 0, \ldots, n-1$. Now, for each $z = 0, \ldots, n-1$ and $k = 0, \ldots, n-z-1$, using that $T_k D(a)$ is a local section of $\mathcal{K}^{k+1}(\mathcal{F})$, Formula (3.5.1) yields the following equation in $S^{n-z}(\mathcal{F})$:

$$\sum (j_k + 1)(\lambda_{j_0} \cdots \lambda_{j_k}) T_k D(a) = \sum_{k=0}^{n-z} \sum_{k+1}(\lambda_{j_0} \cdots \lambda_{j_k}) T_k D(a),$$

where the sum on both sides runs over the $(k+1)$-tuples $(j_0, \ldots, j_k)$ such that $j_0 + \cdots + j_k = n-z-1-k$. Thus, introducing $\ell := k+1$, the right-hand side
for all local sections \( \omega \) becomes
\[
\sum_{\ell=1}^{n} \sum_{p=0}^{\ell-1} \frac{1}{\ell - p} \sum_{z=p}^{n-\ell + p} \sum_{j_0+\cdots+j_{p-1}=n-z+\ell} (\lambda_{j_0} \cdots \lambda_{j_{p-1}}) T_{\ell-p-1} D(a) \omega_{z-p},
\]
whence, introducing \( u := z - p \), equal to
\[
\sum_{\ell=1}^{n} \sum_{p=0}^{\ell-1} \frac{1}{\ell - p} \sum_{u=0}^{\ell-1} \sum_{j_0+\cdots+j_{p-1}=n-\ell-u} (\lambda_{j_0} \cdots \lambda_{j_{p-1}}) T_{\ell-p-1} D(a) \omega_u,
\]
which is equal to (3.6.3). \( \square \)

4. Jets

**Theorem 4.1.** Let \( X \) be a topological space, \( O_B \) a sheaf of \( \mathcal{O} \)-algebras and \( O_X \) a sheaf of \( O_B \)-algebras. Let \( F \) be a sheaf of \( O_X \)-modules and \( D: O_X \to F \) an \( O_B \)-derivation. If \( D \) is integrable, then there exists a flat, extended \( D \)-connection.

**Proof.** Since \( D \) is integrable, there is a flat \( D \)-connection \( T_1: F \to \mathcal{T}^2(F) \). Set \( T_0 := \text{id}_F \). Suppose, by induction, that for an integer \( n \geq 2 \) we have constructed an extended \( D \)-connection
\[
T = (T_0, T_1, \ldots, T_{n-1}): F \to \prod_{i=0}^{n-1} \mathcal{R}^{i+1}(F).
\]
We will also suppose the maps \( T_i \) satisfy one additional property, Equations (4.1.2), after we make a definition.

For each \( j = 0, \ldots, n - 1 \), define a map of \( O_B \)-modules \( T'_j: \mathcal{R}^j(F) \to \mathcal{R}^{j+2}(F) \) by letting
\[
T'_j(m_1 m_2) := \sum_{i=0}^{j} T_i(m_1) T_{j-i}(m_2)
\]
for all local sections \( m_1 \) and \( m_2 \) of \( F \). To check that \( T'_j \) is well defined, we need only check that \( \sum_{i=0}^{j} T_i(m_1) T_{j-i}(m_2) = \sum_{i=0}^{j} T_i(m_1) T_{j-i}(m_2) \) for each local section \( a \) of \( O_X \). In fact, using (2.5.3), we see that both sides are equal to
\[
\sum_{i=0}^{j} \sum_{i=1}^{j-\ell} \sum_{i=0}^{\ell} T_{\ell-i} D(a) T_i(m_1) T_{j-i}(m_2).
\]
Furthermore, we see from this computation that
\[
T'_j(\omega) = a T'_j(\omega) + \sum_{i=1}^{j} \frac{1}{j-i} T_{j-i} D(a) T'_{j-i}(\omega)
\]
for all local sections \( \omega \) of \( \mathcal{R}^j(F) \) and \( a \) of \( O_X \).

Also, notice that \( \sigma^* T'_{i-1}(1 - \sigma) = 0 \). Indeed, for local sections \( m_1 \) and \( m_2 \) of \( F \),
\[
\sigma^* T'_{i-1}(1 - \sigma)(m_1 m_2) = \sigma^* T'_{i-1}(m_1 m_2 - m_2 m_1)
\]
\[
= \sigma^* \left( \sum_{j=0}^{i-1} \left( T_j(m_1) T_{i-1-j}(m_2) - T_{i-1-j}(m_2) T_j(m_1) \right) \right)
\]
\[
= \sum_{j=0}^{i-1} \left( \sigma^* (T_j(m_1) T_{i-1-j}(m_2)) - \sigma^* (T_{i-1-j}(m_2) T_j(m_1)) \right),
\]

which is zero because \( \sigma^*(\omega_1\omega_2) = \sigma^*(\omega_2\omega_1) \) for all local sections \( \omega_1 \) and \( \omega_2 \) of \( \mathcal{R}_+(\mathcal{F}) \). Then

\[
T'_{i-1}(1 - \sigma) = \frac{i - \sigma}{i + 1} T_{i-1}'(1 - \sigma).
\]

Now, suppose that

\[
(i - \sigma)(i + 1)T_i - T_{i-1}'(1 - \sigma)T_1 = 0
\]

for each \( i = 1, \ldots, n-1 \). (Notice that Equation (4.1.2) holds automatically for \( i = 1 \), because \( (1 - \sigma)\sigma^*(\mathcal{R}^2(\mathcal{F})) = 0 \).) Also, from Equation (4.1.2), and the flatness of \( T_1 \), we get \( T_i D(\mathcal{O}_X) \subseteq \mathcal{K}_{i+1}(\mathcal{F}) \) for each \( i = 1, \ldots, n-1 \).

Let

\[
T := \frac{1}{n + 1} T_{n-1}'(1 - \sigma)T_1.
\]

Then

\[
(\sigma - \sigma)(T(\sigma) - \sigma T(m)) - \sum_{i=1}^{n} \frac{1}{\sigma} T_{i-1}D(\sigma)\sigma T_{n-i}(m) = 0
\]

for all local sections \( \sigma \) of \( \mathcal{F} \) and \( m \) of \( \mathcal{O}_X \). Indeed,

\[
(\sigma - \sigma)T(\sigma) = \frac{n - \sigma}{n + 1} T_{n-1}'(1 - \sigma)T_1(\sigma)
\]

\[
= \frac{n - \sigma}{n + 1} \left( T_{n-1}'(D(\sigma)m - mD(\sigma) + a(1 - \sigma)T_1(m)) \right)
\]

\[
= \frac{n - \sigma}{n + 1} \left( T_{n-1}D(\sigma)m + \sum_{i=1}^{n-1} T_{n-1-i}D(\sigma)T_i(m) \right)
\]

\[
- \frac{n - \sigma}{n + 1} \left( mT_{n-1}D(\sigma) + \sum_{i=1}^{n-1} T_i(m)T_{n-1-i}D(\sigma) \right)
\]

\[
+ \frac{n - \sigma}{n + 1} \left( aT_{n-1}'(1 - \sigma)T_1(m) \right)
\]

\[
+ \frac{n - \sigma}{n + 1} \left( \sum_{i=1}^{n-1} T_{n-1-i}D(\sigma)T_{i-1}' \frac{1 - \sigma}{n - i} T_i(m) \right).
\]

Now, first observe that, for each \( i = 0, \ldots, n-1 \), we have \( (n-i-\sigma)T_{n-1-i}D(\sigma) = 0 \), since \( T_{n-1-i}D(\sigma) \) is a local section of \( \mathcal{K}^{n-i}(\mathcal{F}) \). Then

\[
(\sigma - \sigma)T_1T_{n-1-i}D(m) = (\sigma - \sigma)T_1(m) \frac{\sigma^*}{n-i} T_{n-1-i}D(\sigma)
\]

\[
= - \frac{n - \sigma}{n - i} \left( T_{n-1-i}D(\sigma) \sigma^* T_i(m) \right).
\]

Also, from (4.1.1) and (4.1.2),

\[
T_{n-i-1}D(\sigma)T_{i-1}'(1 - \sigma)T_1(m) = T_{n-i-1}D(\sigma) \frac{i - \sigma}{i + 1} T_{i-1}'(1 - \sigma)T_1(m)
\]

\[
= T_{n-i-1}D(\sigma)(i - \sigma)T_i(m)
\]

for each \( i = 1, \ldots, n-1 \). So

\[
\frac{n - \sigma}{n + 1} \left( T_{n-1}D(\sigma)m - mT_{n-1}D(\sigma) \right) = \frac{n - \sigma}{n} \left( T_{n-1}D(\sigma)m \right),
\]
and, for each \(i = 1, \ldots, n - 1\),
\[
\frac{n - \sigma}{n + 1} \left( T_{n-1-i}D(a)T_i(m) - T_i(m)T_{n-1-i}D(a) + T_{n-i-1}D(a)T_i' - \frac{1 - \sigma}{n - i}T_i(m) \right)
\]
is equal to
\[
\frac{n - \sigma}{n + 1} \left( T_{n-1-i}D(a)(1 + \frac{1 + \sigma}{n - i} + \frac{i - \sigma}{n - i})T_i(m) \right),
\]
whence equal to
\[
\frac{n - \sigma}{n - i} \left( T_{n-1-i}D(a)T_i(m) \right).
\]
Applying these equalities in the above expression for \((n - \sigma)T(am)\) we get Equation (4.1.3).

We want to show that there exists a map of \(O_B\)-modules \(T_n : F \rightarrow R^{n+1}(F)\) such that (4.1.2) holds for \(i = n\), and such that \((T_0, \ldots, T_n)\) is an extended \(D\)-connection. First we claim that there exists a map of \(O_B\)-modules \(T_n : F \rightarrow R^{n+1}(F)\) such that \((T_0, \ldots, T_n)\) is an extended \(D\)-connection. Indeed, from \(T_1\) construct an extended \(D\)-connection \((S_0, \ldots, S_n)\) by iteration, as described in Construction 2.5. By Proposition 2.6 there is a map of \(O_X\)-modules
\[
\lambda = (\lambda_0, \lambda_1, \ldots, \lambda_{n-1}) : F \rightarrow \prod_{i=0}^{n-1} R^{i+1}(F)
\]
such that \(\lambda_0 = \text{id}_F\) and such that Equations (3.6.1) hold for \(i = 0, \ldots, n - 1\). Now, just set \(\lambda_n := 0\) in Equation (3.6.1) for \(i = n\), and let it define \(T_n\). Then, by Proposition 2.6 the map \((T_0, \ldots, T_n)\) is an extended \(D\)-connection.

The above map \(T_n\) does not necessarily make (4.1.2) hold for \(i = n\). So, rename it by \(U\). At any rate, since \((T_0, \ldots, T_{n-1}, U)\) is an extended \(D\)-connection, it follows from Equation (4.1.3) that \((n - \sigma)(U - T)\) is \(O_X\)-linear. Set
\[
T_n := U - \frac{(n - \sigma)}{n + 1} (U - T).
\]
Then \(T_n\) differs from \(U\) by an \(O_X\)-linear map, and thus \((T_0, \ldots, T_n)\) is an extended \(D\)-connection. Now,
\[
(n - \sigma)T_n = (n - \sigma)U - \frac{(n - \sigma)^2}{n + 1} (U - T).
\]
Since
\[
(n - \sigma)^2 |_{R^{n+1}(F)} = (n + 1)(n - \sigma) |_{R^{n+1}(F)},
\]
we get \((n - \sigma)T_n = (n - \sigma)T\). So (4.1.2) holds for \(i = n\).

The induction argument is complete, showing that there is an infinite extended \(D\)-connection
\[
T = (T_0, T_1, \ldots) : F \rightarrow \prod_{i=0}^{\infty} R^{i+1}(F)
\]
such that (4.1.2) holds for each \(i \geq 1\), and thus \(T_i D(O_X) \subseteq K^{i+1}(F)\) for each \(i \geq 0\). 

\(\square\)

**Definition 4.2.** Let \(X\) be a topological space, \(O_B\) a sheaf of \(Q\)-algebras and \(O_X\) a sheaf of \(O_B\)-algebras. Let \(F\) be a sheaf of \(O_X\)-modules. Two Hasse derivations \(h\) and \(h'\) of \(F\) are said to be **equivalent** if there is an \(O_X\)-algebra automorphism \(\phi\)
of $\mathcal{S}(\mathcal{F})$ such that $\phi_0|_\mathcal{F} = \text{id}_\mathcal{F}$ and $h' = \phi h$. We say that $h$ and $h'$ are canonically equivalent when there is only one such automorphism.

**Corollary 4.3.** Let $X$ be a topological space, $\mathcal{O}_B$ a sheaf of $\mathcal{Q}$-algebras and $\mathcal{O}_X$ a sheaf of $\mathcal{O}_B$-algebras. Let $\mathcal{F}$ be a sheaf of $\mathcal{O}_X$-modules and $D: \mathcal{O}_X \to \mathcal{F}$ an $\mathcal{O}_B$-derivation. Let $h$ and $h'$ be iterated Hasse derivations of $\mathcal{F}$ extending $D$. If $D$ is integrable, then $h$ and $h'$ are equivalent. Furthermore, if $\nu D(\mathcal{O}_X) \neq 0$ for every nonzero $\mathcal{O}_X$-linear map $\nu: \mathcal{F} \to \mathcal{S}(\mathcal{F})$, then $h$ and $h'$ are canonically equivalent.

**Proof.** First, we prove the existence of an equivalence. By Theorem 4.1, there is a flat, extended $D$-connection $T = (T_0, T_1, \ldots)$. We may suppose $h$ arises from $T$. Let $S = (S_0, S_1, \ldots)$ be an extended $D$-connection from which $h'$ arises.

By Proposition 3.6 there is a map of $\mathcal{O}_X$-modules

$$\lambda = (\lambda_0, \lambda_1, \ldots): \mathcal{F} \to \prod_{i=0}^{\infty} R^{q+1}(\mathcal{F})$$

such that $\lambda_0 = \text{id}_\mathcal{F}$ and

$$(4.3.1) \quad S_i = \sum_{\ell=0}^{i} s_{i-\ell}(\ell)T_\ell \quad \text{for each } i \geq 0.$$

Let $\phi: \mathcal{S}(\mathcal{F}) \to \mathcal{S}(\mathcal{F})$ be the map of $\mathcal{O}_X$-algebras whose graded part $\phi_q$ of degree $q$ satisfies $\phi_q|_{\mathcal{S}^p(\mathcal{F})} = \tilde{s}_q(\lambda)|_{\mathcal{S}^p(\mathcal{F})}$ for all integers $p > 0$ if $q \geq 0$, and $\phi_q = 0$ if $q < 0$. Since $\lambda_0 = \text{id}_\mathcal{F}$, the homogeneous degree-0 part $\phi_0$ is the identity, and thus $\phi$ is an automorphism. We claim that $h' = \phi h$.

Indeed, clearly $h'_0 = (\phi h)_0$. Now, since $T$ is flat, $T_0 D(\mathcal{O}_X) \subseteq K^{q+1}(\mathcal{F})$ for each $q \geq 0$. Thus, for each $i \geq 0$ and each local section $a$ of $\mathcal{O}_X$, using Equations (3.5.1) and (4.3.1), the following equalities hold on $\mathcal{S}^{q+1}(\mathcal{F})$:

$$h'_{i+1}(a) = \frac{S_i D(a)}{i+1} = \sum_{\ell=0}^{i} s_{i-\ell}(\ell) T_\ell \frac{D(a)}{i+1} = \sum_{\ell=0}^{i} s_{i-\ell}(\ell) \frac{T_\ell D(a)}{i+1} = \sum_{\ell=0}^{i} \phi_{i-\ell} h_{\ell+1}(a).$$

Since $\phi_{i+1}|_{\mathcal{O}_X} = 0$, we have $h'_{i+1} = (\phi h)_{i+1}$. So $h' = \phi h$.

Now, assume that $\nu D(\mathcal{O}_X) \neq 0$ for every nonzero $\mathcal{O}_X$-linear map $\nu: \mathcal{F} \to \mathcal{S}(\mathcal{F})$. Let $\phi$ be an $\mathcal{O}_X$-algebra automorphism of $\mathcal{S}(\mathcal{F})$ such that $\phi_0|_\mathcal{F} = \text{id}_\mathcal{F}$ and $h' = \phi h$. To see that $\phi$ is unique, we just need to show that $\phi_q|_\mathcal{F}$ is uniquely defined for each $q \geq 0$. We do it by induction. Since $h' = \phi h$, for each $q \geq 0$ the following equality holds:

$$h'_{q+1} = \phi_q h_1 + \phi_{q-1} h_2 + \cdots + \phi_1 h_q + h_{q+1}.$$

Then $\phi_q D$ is determined by $\phi_1, \ldots, \phi_{q-1}$. Since $\phi_q$ is $\mathcal{O}_X$-linear and takes values in $\mathcal{S}^{q+1}(\mathcal{F})$, it follows from our extra assumption that $\phi_q$ is determined.

If $(X, \mathcal{O}_X)$ is a Noetherian scheme over a Noetherian $\mathcal{Q}$-scheme $(B, \mathcal{O}_B)$, and $\mathcal{F}$ is a locally free sheaf on $X$, then, for every $\mathcal{O}_B$-derivation $D: \mathcal{O}_X \to \mathcal{F}$ such that $\mathcal{F}$ is generated by $D(\mathcal{O}_X)$ at the associated points of $X$, we have $\nu D(\mathcal{O}_X) \neq 0$ for all nonzero $\mathcal{O}_X$-linear maps $\nu: \mathcal{F} \to \mathcal{S}(\mathcal{F})$.

**Construction 4.4. (Jets)** Let $X$ be a topological space, $\mathcal{O}_B$ a sheaf of $\mathcal{Q}$-algebras, and $\mathcal{O}_X$ a sheaf of $\mathcal{O}_B$-algebras. Let $\mathcal{F}$ be a sheaf of $\mathcal{O}_X$-modules and $D: \mathcal{O}_X \to \mathcal{F}$ an $\mathcal{O}_B$-derivation. Assume that $D: \mathcal{O}_X \to \mathcal{F}$ is locally integrable, and that the sheaf of $\mathcal{O}_X$-linear maps from $\mathcal{F}$ to $\mathcal{S}(\mathcal{F})$ sending $D(\mathcal{O}_X)$ to zero has only trivial local sections. Let $\mathcal{U}$ be the collection of open subspaces $\mathcal{U} \subseteq X$ such that $D|_\mathcal{U}$ is
Let \( h, h' \in \mathcal{C}_U \) be the collection of all the \( \phi \) integrable. For each \( U \) the patching of the latter yields the bundle of jets \( h \). Now, consider the collection of all the \( h \) for all \( U \) in \( \mathcal{C}_U \). Consider also the collection of all the \( \phi_{h,h'} \) for each \( U \) in \( \mathcal{C}_U \). If \( h, h', h'' \in \mathcal{C}_U \), then \( h'' = \phi_{h,h''} \phi_{h,h'} h \). From the uniqueness of \( \phi_{h,h''} \), we get \( \phi_{h',h''} \phi_{h,h'} = \phi_{h,h''} \).

The cocycle condition being satisfied, the \( \phi_{h,h'} \) patch the \( S(F|U) \) to an \( \mathcal{O}_X \)-algebra \( J \), and the \( h \) patch to a map of \( \mathcal{O}_B \)-algebras \( \tau : \mathcal{O}_X \rightarrow J \). Since the \( \phi_{h,h'} \) do not decrease degrees, for each integer \( n \geq 0 \) the truncated sheaves \( \prod_{i=0}^{n} S_i(F|U) \) patch to an \( \mathcal{O}_X \)-algebra quotient \( J^n \) of \( J \). Also, since the \( (\phi_{h,h'})_0 \) are the identity maps, there is a natural map of \( \mathcal{O}_X \)-modules \( S^n(F) \rightarrow J^n \). This map is an isomorphism for \( n = 0 \). Also, for each integer \( n > 0 \), the \( \mathcal{O}_X \)-algebra \( J^{n-1} \) is a quotient of \( J^n \), and there is a natural exact sequence,

\[
0 \rightarrow S^n(F) \rightarrow J^n \rightarrow J^{n-1} \rightarrow 0.
\]

We say that \( J \) is the sheaf of jets of \( D \), and that \( \tau : \mathcal{O}_X \rightarrow J \) is its Hasse derivation.

For each integer \( n \geq 0 \), we say that \( J^n \) is the sheaf of \( n \)-jets of \( D \), and that the induced \( \tau_n : \mathcal{O}_X \rightarrow J^n \) is the \( n \)-th order truncated Hasse derivation.

**Example 4.5.** Let \( M \) be a complex manifold of complex dimension \( m \), and \( \mathcal{L} \) a foliation of dimension \( n \) of \( M \). Let \( w : T_M \rightarrow E \) be the surjection associated to \( \mathcal{L} \). Then \( w \) induces a derivation \( D : \mathcal{O}_M \rightarrow \mathcal{F} \), where \( \mathcal{F} \) is the sheaf of holomorphic sections of \( E \). The Frobenius conditions imply that \( \mathcal{F} \) is integrable. Also, since \( w \) is surjective, \( \mathcal{F} \) is generated by \( D(\mathcal{O}_M) \). Thus, applying Construction 4.1 we have an associated sheaf of \( q \)-jets \( J^q \) on \( M \) for each integer \( q \geq 0 \). Also we may consider the bundle of \( q \)-jets \( J^q_{\mathcal{L}} \) of \( \mathcal{L} \). Then \( J^q \) is the sheaf of holomorphic sections of \( J^q_{\mathcal{L}} \).

Indeed, for each point \( p \) of \( M \), there exist a neighborhood \( X \) of \( p \) in \( M \), and an open embedding of \( X \) in \( \mathbb{C}^n \times \mathbb{C}^{m-n} \) whose composition \( \varphi_X : X \rightarrow \mathbb{C}^{m-n} \) with the second projection defines \( \mathcal{L} \) on \( X \). The sheaf \( \mathcal{F}|_{\mathcal{X}} \) is the pullback of the sheaf of \( 1 \)-forms on \( \mathbb{C}^n \), and the canonical vector fields on \( \mathbb{C}^n \) yield a basis \( e_1, \ldots, e_n \) of \( \mathcal{F}|_{\mathcal{X}} \) such that \( D = D_1 e_1 + \cdots + D_n e_n \), where the \( D_i \) are the pullbacks of these vector fields. Since they commute, so do the \( D_i \).

Using the \( D \)-connection \( \gamma \) given in Example 3.2 and the associated extended \( D \)-connection \( T \) given in Construction 2.5 we obtain an iterated Hasse derivation \( h_X \) on \( X \) extending \( D|_{\mathcal{X}} \), and given by Formula 3.2 for each integer \( q > 0 \) and each local section \( a \) of \( \mathcal{F} \). Then the truncation in order \( q \) of \( h_X \) has exactly the same form of the canonical Hasse derivation of the sheaf of sections of the bundle of relative \( q \)-jets \( J^q_{\varphi_X} \). So, patching the \( h_X \) is compatible with patching the \( J^q_{\varphi_X} \). The patching of the latter yields the bundle of jets \( J^q_{\mathcal{L}} \), and hence we get that \( J^q \) is the sheaf of sections of \( J^q_{\mathcal{L}} \).
