LOCAL CLASSIFICATION OF GENERALIZED COMPLEX STRUCTURES

MICHAEL BAILEY

Abstract. We give a local classification of generalized complex structures. About a point, a generalized complex structure is equivalent to a product of a symplectic manifold with a holomorphic Poisson manifold. We use a Nash-Moser type argument in the style of Conn’s linearization theorem.

1. Introduction

Generalized complex geometry is a generalization of both symplectic and complex geometry, introduced by Hitchin [12], and developed by Gualtieri (we refer to his recent publication [10] rather than his thesis), Cavalcanti [3] and others. Its applications include the study of 2-dimensional supersymmetric quantum field theories, which occur in topological string theory, as well as compactifications of string theory with fluxes, and mirror symmetry.

Definition 1.1. A generalized complex structure on a manifold $M$ is a complex structure, $J = -1$, on the vector bundle $TM \oplus T^*M$, which is orthogonal with respect to the standard symmetric pairing, and whose $+i$-eigenspace is involutive with respect to the Courant bracket, defined as follows: let $X, Y \in \Gamma(TM)$ and $\xi, \eta \in \Gamma(T^*M)$; then

$$[X + \xi, Y + \eta] = [X, Y]_{\text{Lie}} + \mathcal{L}_X \eta - \iota_Y d\xi.$$  

The Courant bracket (actually, in this form, due to Dorfman [7]) usually has an additional twisting term involving a closed 3-form. However, every such bracket is in a certain sense locally equivalent to the untwisted bracket above, and since this paper studies the local structure of generalized complex structures, we ignore the twisting for now.

Example 1.2. If $\omega : TM \to T^*M$ is a symplectic structure, then

$$J_\omega = \begin{bmatrix} 0 & -\omega^{-1} \\ \omega & 0 \end{bmatrix}$$

is a generalized complex structure.

Example 1.3. If $I : TM \to TM$ is a complex structure, then

$$J_I = \begin{bmatrix} -I & 0 \\ 0 & I^* \end{bmatrix}$$

is a generalized complex structure.

Remark 1.4. A generalized complex structure may be of complex type or symplectic type at a point $p$, if it is of one of the above forms on $T_pM \oplus T^*_pM$, while having a different type elsewhere.
Example 1.5. If $J_1$ is a generalized complex structure on $M_1$ and $J_2$ is a generalized complex structure on $M_2$, then $J_1 \times J_2$ is a generalized complex structure on $M_1 \times M_2$ in the obvious way.

Definition 1.6. A Courant isomorphism $\Phi : TM \oplus T^*M \rightarrow TN \oplus T^*N$ is a vector bundle isomorphism of $TM \oplus T^*M$ to $TN \oplus T^*N$ which respects the Courant bracket, the symmetric pairing, and the projection to the tangent bundle.

The first result on the local structure of generalized complex structures was due to Gualtieri [10]. It was strengthened by Abouzaid and Boyarchenko [1], as follows:

Theorem 1.7 (Abouzaid, Boyarchenko). If $M$ is a generalized complex manifold and $p \in M$, then there is a neighbourhood of $p$ which is isomorphic, via Courant isomorphism, to a product of a generalized complex manifold which is symplectic everywhere and a generalized complex manifold which is of complex type at the image of $p$.

This resembles Weinstein’s local structure theorem for Poisson structures [19]. In fact, a generalized complex structure induces a Poisson structure, for which this result produces the Weinstein decomposition.

Thus, the remaining question in the local classification of generalized complex structures is: what kinds of generalized complex structures occur near a point of complex type? There is a way in which any holomorphic Poisson structure (see Section 1.1 below) induces a generalized complex structure (as described in Section 2). Our main result, then, is as follows:

Main Theorem. Let $J$ be a generalized complex structure on a manifold $M$ which is of complex type at point $p$. Then, in a neighbourhood of $p$, $J$ is Courant-equivalent to a generalized complex structure induced by a holomorphic Poisson structure, for some complex structure near $p$.

This is finally proven in Section 7. Most of the work happens in earlier sections, in proving the following lemma:

Main Lemma. Let $J$ be a generalized complex structure on the closed unit ball $B_1$ about the origin in $\mathbb{C}^n$. Suppose $J$ is a small enough deformation of the complex structure on $B_1$, and suppose that $J$ is of complex type at the origin. Then, in a neighbourhood of the origin, $J$ is Courant-equivalent to a deformation of the complex structure by a holomorphic Poisson structure on $\mathbb{C}^n$.

In Section 2, we explain how one generalized complex structure may be understood as a deformation of another. By the smallness condition we mean that there is some $l \in \mathbb{N}$ such that if the deformation is small enough in its $C^l$-norm then the conclusion holds. (See Section 5.1 for details about the norms.) The proof of the Main Lemma is in Section 4.3 (modulo technical results in Sections 5 and 6).

In some sense, then, generalized complex structures are holomorphic Poisson structures twisted by (possibly) non-holomorphic Courant gluings. A generalized complex manifold may not, in general, admit a global complex structure [4] [5], emphasizing the local nature of our result.

Remark 1.8. Throughout this paper, we assume that all functions and sections are $C^\infty$-smooth, though in fact this is not a major point. The arguments carry through for finite smoothness class, and then the condition of holomorphicity implies that, in the adapted local coordinates, the structure is in fact $C^\infty$. 
1.1. Holomorphic Poisson structures. A holomorphic Poisson structure on a complex manifold $M$ is given by a holomorphic bivector field $\beta \in \Gamma(\wedge^2 T_{1,0}M)$, $\bar{\partial}\beta = 0$, for which the Schouten bracket, $[\beta, \beta]$, vanishes. $\beta$ determines a Poisson bracket on holomorphic functions, $\{f, g\} = \beta(df, dg)$. The holomorphicity condition, $\bar{\partial}\beta = 0$, means that, if $\beta$ is written in local coordinates,

$$\beta = \sum_{i,j} \beta_{ij} \frac{d}{dz_i} \wedge \frac{d}{dz_j},$$

then the component functions, $\beta_{ij}$, are holomorphic. For a review of holomorphic Poisson structures see [13].

The type-change locus of a generalized complex structure induced by a holomorphic Poisson structure, that is, the locus where the Poisson rank changes, is determined by the vanishing of an algebraic function of the component functions above, thus,

**Corollary 1.9.** The type-change locus of a generalized complex structure locally admits the structure of an analytic subvariety.

After a review of the literature we believe the following to be an open question: is every holomorphic Poisson structure locally equivalent to one which is polynomial in some coordinates? We are unaware of any counterexamples, and there are some partial results [8] [15].

1.2. Outline of the proof of the Main Lemma. In Section 2 we describe the deformation complex for generalized complex structures, and how it interacts with Courant flows coming from generalized vector fields. In Section 3 we solve an infinitesimal version of the problem, by showing that, to first order, an infinitesimal generalized complex deformation of a holomorphic Poisson structure is equivalent to another holomorphic Poisson structure. Then the full problem is solved by iterating an approximate version of the infinitesimal solution:

At each stage of the iteration, we have a generalized complex structure which is a deformation of a given complex structure. We seek to cancel the part of this deformation which is not a Poisson bivector. We construct a generalized vector field whose Courant flow acting on the deformation should cancel this non-bivector part, to first order. Then after each stage the unwanted part of the deformation should shrink quadratically. We mention two issues with this algorithm:

Firstly, at each stage we “lose derivatives,” meaning that the $C^k$-convergence will depend on ever higher $C^{k+i}$-norms. The solution is to apply Nash’s smoothing operators at each stage to the generalized vector field, where the smoothing degree is carefully chosen to compensate for loss of derivatives while still achieving convergence. A good general reference for this sort of technique (in the context of compact manifolds) is [11], and it is tempting to try to apply the Nash-Moser implicit function theorem directly. However, this is frustrated by the second issue:

Since we are working on a neighbourhood of a point $p$, the generalized vector field will not integrate to a Courant automorphism of the whole neighbourhood. Thus, after each stage we may have to restrict our attention to a smaller neighbourhood of $p$. If the radius restriction at each stage happens in a controlled way, then the limit will be defined on a ball of radius greater than 0. The technique for proving Nash-Moser type convergence results on shrinking neighbourhoods comes from Conn [6].
We adopt a more recent formalization of this technique, by Miranda, Monnier and Zung [16] [17] (Section 4). In fact, for much of the work we use a general technical lemma of theirs (Theorem 4.17) with only a few changes. Even so, we must prove estimates for the behaviour of Courant flows acting on deformations (see Sections 5 and 6).

Remark 1.10. We had hoped there was an easier approach to the proof. In trying “softer” geometric methods, we encountered various obstacles. Of course, methods involving power series are unlikely to work, since in this case they would be question-begging. For a Moser-type argument, we would need to specify concretely a path from the given generalized complex structure to a holomorphic one, and then show that this path of structures is generated by pushforward under a family of Courant automorphisms; however, it is not a trivial task to pick out which holomorphic Poisson structure ought to be at the endpoint of this path, and even if we were to make the right choice, there would be no obvious way to interpolate between the two structures. Arguments that directly employ an implicit function theorem, like Kuranishi’s proof of the deformation theorem for complex structures, fail for reasons discussed above.

1.3. Acknowledgements. This paper is drawn from Chapter 2 of my Ph.D. thesis [2]. During my time in graduate school at the University of Toronto, I received support, both material and mathematical, from many sources. In particular I would like to thank my advisors, Marco Gualtieri and Yael Karshon, as well as Brent Pym, Jordan Watts, Jordan Bell and Ida Bulat.

2. The deformation complex

In this section, if $V$ is a vector bundle, let $\Gamma(V)$ denote its smooth sections. We will now describe the deformation complex for generalized complex structures. Except where we remark otherwise, the results in this section (2) can be found in Section 5 of [10]. We make use of the fact that a generalized complex structure is determined by its $+i$-eigenbundle.

Let $T$ be the tangent bundle of some manifold $M$. Let $L \subset \mathbb{C} \otimes (T \oplus T^*)$ be the $+i$-eigenbundle for an initial generalized complex structure. We will often take this initial structure to be induced by a complex structure as in Example 1.3, in which case

$$L = T_{0,1} \oplus T^*_{1,0}.$$  

Another example arises from a holomorphic Poisson structure. If $\beta : T^*_{1,0} \to T_{1,0}$ is a holomorphic Poisson bivector, then we define the corresponding generalized complex structure, with $+i$-eigenbundle

$$L = T_{0,1} \oplus \text{graph}(\beta).$$  

(2.1)

In any case, the $+i$-eigenbundle of a generalized complex structure is a maximal isotropic subbundle. Using the pairing, we choose an embedding of $L^* \subset T^*_C \oplus T_{C}^*$, which will be transverse to $L$ and isotropic with respect to the standard symmetric pairing. One choice is $L^* \simeq \bar{L}$, though we may take others. Any maximal isotropic $L_\varepsilon$ close to $L$ may thus be realized as

$$L_\varepsilon = (1 + \varepsilon)L,$$

where $\varepsilon : L \to L^* \subset T^*_C \oplus T_{C}^*$. As a consequence of the maximal isotropic condition on $L_\varepsilon$, $\varepsilon$ will be antisymmetric, and we can say that $\varepsilon \in \Gamma(\wedge^2 L^*)$. In fact, for any
\(\varepsilon \in \Gamma(\wedge^2 L^*)\), \(L\) is the \(+i\)-eigenbundle of an almost generalized complex structure. Of course, for \(L\) to be integrable, \(\varepsilon\) must satisfy a differential condition—the Maurer-Cartan equation (see Section 2.2).

Remark 2.1. When the initial structure is complex, we will use the convention \(L^* \simeq \bar{L}\), so that \(L^* = T_{1,0} \oplus T_{0,1}\). Since the only requirement on the embedding of \(L^*\) is that it be transverse to \(L\) and isotropic (and thus give a representation of \(L^*\) by the pairing), we will take this same choice of \(L^*\) whenever possible; that is, we henceforth fix the notation

\[
(2.3) \quad L^* = T_{1,0} \oplus T_{0,1},
\]

regardless of which eigenbundle \(L\) we are dealing with.

Remark 2.2. If the initial structure is complex and \(\varepsilon = \beta \in \Gamma(\wedge^2 T_{1,0})\) is a holomorphic Poisson bivector, then the deformed eigenbundle \(L\) agrees with (2.1).

2.1. Generalized Schouten bracket and Lie bialgebroid structure. While \(T \oplus T^*\) is not a Lie algebroid for the Courant bracket (which isn’t antisymmetric), the restriction of the bracket to \(L\) does give a Lie algebroid structure. From this, there is a naturally-defined differential

\[
d_L : \Gamma(\wedge^k L^*) \to \Gamma(\wedge^{k+1} L^*)
\]

as well as an extension of the bracket (in the manner of Schouten) to higher wedge powers of \(L\). But \(L^*\) is also a Lie algebroid, and the same structures apply. Together they form a Lie bialgebroid (actually, a differential Gerstenhaber algebra if we consider the wedge product), meaning that \(d_L\) is a derivation for the bracket on \(\wedge^* L^*\):

\[
(2.4) \quad d_L[\alpha, \beta] = [d_L\alpha, \beta] + (-1)^{|\alpha|-1}\{\alpha, d_L\beta\}
\]

For more details on Lie bialgebroids see [14], and for their relation to generalized complex structures see [9] and [10].

Example 2.3. If \(L\) corresponds to a complex structure, then \(d_L = \bar{\partial}\). We can find the differential for other generalized complex structures by using the following fact, quoted from [9]:

Proposition 2.4. Let \(L\) be an integrable deformation of a generalized complex structure \(L\) by \(\varepsilon \in \wedge^2 L^*\). As per Remark 2.1, we identify \(L^*_\varepsilon = L^* = \bar{L}\), and thus identify their respective differential complexes as sets. Then for \(\sigma \in \Gamma(\wedge^k L^*)\),

\[
d_{L,\sigma} = d_L\sigma + [\varepsilon, \sigma].
\]

Example 2.5. Thus, the differential on \(\Gamma(\wedge^k L^*)\) coming from a holomorphic Poisson structure \(\beta \in \Gamma(\wedge^2 T_{1,0})\) is just

\[
d_{L,\beta} = \bar{\partial} + d_\beta,
\]

where \(d_\beta\) is the usual Poisson differential \([\beta, \cdot]\).

2.2. Integrability and the Maurer-Cartan equation. For a deformed structure \(L\) to be integrable, \(\varepsilon\) must satisfy the Maurer-Cartan equation,

\[
(2.5) \quad d_L\varepsilon + \frac{1}{2}[\varepsilon, \varepsilon] = 0
\]
Notation 2.6. Suppose $L$ is the $+i$-eigenbundle for the generalized complex structure on $\mathbb{C}^n$ coming from the complex structure and that $L^* = T_{1,0} \oplus T_{0,1}$, as in Remark 2.1. We may write
\[
\wedge^2 L^* = (\wedge^2 T_{1,0}) \oplus (T_{1,0} \otimes T_{0,1}^* \oplus (\wedge^2 T_{0,1}^*).
\]
If $\varepsilon \in \Gamma(\wedge^2 L^*)$ is a deformation, we will write $\varepsilon$ correspondingly as $\varepsilon_1 + \varepsilon_2 + \varepsilon_3$, where $\varepsilon_1$ is a bivector field, $\varepsilon_2 \in \Gamma(T_{1,0} \otimes T_{0,1}^*)$, and $\varepsilon_3$ is a 2-form.

Then the Maurer-Cartan condition (2.5) on $\varepsilon$ splits into four equations:
\[
\wedge^3 T_{1,0} : [\varepsilon_1, \varepsilon_1] = 0
\]
\[
\wedge^2 T_{1,0} \otimes T_{0,1}^* : [\varepsilon_1, \varepsilon_2] + \bar{\partial} \varepsilon_1 = 0
\]
\[
T_{1,0} \otimes \wedge^2 T_{0,1}^* : \frac{1}{2}[\varepsilon_2, \varepsilon_2] + [\varepsilon_1, \varepsilon_3] + \bar{\partial} \varepsilon_2 = 0
\]
\[
\wedge^3 T_{0,1}^* : \bar{\partial} \varepsilon_3 = 0
\]

Remark 2.7. By (2.6), $\varepsilon_1$ always satisfies the Poisson condition. If $\varepsilon_2 = 0$ then, by (2.7), $\varepsilon_1$ is also holomorphic. Therefore, to say that an integrable deformation $\varepsilon$ is holomorphic Poisson is the same as to say that $\varepsilon_2$ and $\varepsilon_3$ vanish, that is, that $\varepsilon$ is just a bivector.

2.3. Courant automorphisms.

Definition 2.8. A Courant automorphism $\Phi : T \oplus T^* \rightarrow T \oplus T^*$, also called a generalized diffeomorphism, is an isomorphism of $T \oplus T^*$ (covering some diffeomorphism) which respects the Courant bracket, the symmetric pairing, and the projection to the tangent bundle.

A $B$-transform is a particular kind of Courant automorphism: if $B : T \rightarrow T^*$ is a closed 2-form and $X + \xi \in T \oplus T^*$, then we say that $e^B(X + \xi) = (1 + B)(X + \xi) = X + \iota_X B + \xi$.

Another kind of Courant automorphism is a diffeomorphism acting by pushforward (which means inverse pullback on the $T^*$ component). We will typically identify a Courant automorphism $\Phi$ with a pair $(B, \varphi)$, where $B$ is a closed 2-form and $\varphi$ is a diffeomorphism—then $\Phi$ acts first through a $B$-transform and then through pushforward by $\varphi_\ast$.

Such pairs exhaust the Courant automorphisms [10].

Remark 2.9. Let $\Phi = (B, \varphi)$ and $\Psi = (B', \psi)$ be Courant automorphisms. Then
\[
\Phi \circ \Psi = (\psi^\ast(B) + B', \varphi \circ \psi) \quad \text{and} \quad \Phi^{-1} = (-\varphi_\ast(B), \varphi^{-1})
\]

Definition 2.10. If $v : M \rightarrow TM \oplus T^* M$ is a section of a Courant algebroid and $\Phi = (B, \varphi)$ is a Courant automorphism, then the pushforward of $v$ by $\Phi$ is
\[
\Phi_\ast v = \Phi \circ v \circ \varphi^{-1}.
\]

Definition 2.11. If $L_\varepsilon$ is a deformation of generalized complex structure $L$, and $\Phi$ is a Courant automorphism of sufficiently small 1-jet, then $\Phi(L_\varepsilon)$ is itself a deformation of $L$. Let $\Phi \cdot \varepsilon \in \Gamma(\wedge^2 L^*)$ be such that $L_{\Phi \cdot \varepsilon} = \Phi(L_\varepsilon)$, that is,
\[
(1 + \varepsilon)L = (1 + \Phi \cdot \varepsilon)L.
\]

Remark 2.12. For a more concrete formula for $\Phi \cdot \varepsilon$, see Proposition 5.8. In general $\Phi \cdot \varepsilon$ should not be understood as a pushforward of the tensor $\varepsilon$. (In fact, $\Phi \cdot 0$ may be nonzero!) However, if $\Phi(L) = L$ then indeed $\Phi \cdot \varepsilon = \Phi_\ast(\varepsilon)$ suitably interpreted.
Definition 2.13. A section \( v \in \Gamma(T \oplus T^*) \) is called a \textit{generalized vector field}. We say that \( v \) generates the 1-parameter family \( \Phi_{tv} \) of generalized diffeomorphisms if for any section \( \sigma \in T \oplus T^* \),

\[
\frac{d}{dt} \bigg|_{t=0} (\Phi_{tv})_* \sigma = [v, (\Phi_{tv})_* \sigma].
\]

(2.11)

The generalized diffeomorphism thus defined is related to a classically generated diffeomorphism as follows:

Let \( v = X + \xi \), where \( X \) is a vector field and \( \xi \) a 1-form. If \( X \) is small enough, or the manifold is compact, then it integrates to the diffeomorphism \( \varphi_X \) which is its time-1 flow. Let

\[
B_v = \int_0^1 \varphi_{tX}^*(d\xi) dt.
\]

Then \( \Phi_v = (B_v, \varphi_X) \) is the time-1 Courant flow of \( v \).

Remark 2.14. If \( X \) does not integrate up to time 1 from every point, then \( \varphi_X \), and thus \( \Phi_v \), is instead defined on a subset of the manifold. In this case, \( \Phi_v \) is a \textit{local} Courant automorphism (or \textit{local} generalized diffeomorphism).

Remark 2.15. While (2.11) gives the derivative of a Courant flow acting by push-forward on a tensor, it does not hold for derivatives of Courant flows acting by the deformation action of Definition 2.11, as we see from Remark 2.12.

The following is a corollary to [10, Prop. 5.4]:

Lemma 2.16. If \( 0 \in \Gamma(\wedge^2 L^*) \) is the trivial deformation of \( L \) and \( v \in \Gamma(T \oplus T^*) \), then

\[
\frac{d}{dt} \Phi_{tv} \cdot 0 \bigg|_{t=0} = d_L v^{0,1},
\]

where \( v^{0,1} \) is the projection of \( v \) to \( L^* \).

Then combining this fact with Proposition 2.4 we see that

Proposition 2.17. If \( \varepsilon \in \Gamma(\wedge^2 L^*) \) is an integrable deformation of \( L \), and \( v \in \Gamma(T \oplus T^*) \), then

\[
\frac{d}{dt} \Phi_{tv} \cdot \varepsilon \bigg|_{t=0} = d_L v^{0,1} + [\varepsilon, v],
\]

where \( v^{0,1} \) is the projection of \( v \) to \( L^* \).

Remark 2.18. Definition 2.13 makes sense if \( v \) is a real section of \( T \oplus T^* \). On the other hand, if \( v \in \Gamma(T_C \oplus T_C^*) \) is complex, we may interpret \( \Phi_v \) in the presence of an underlying generalized complex structure as follows. \( v \) decomposes into \( v^{1,0} \in L \) plus \( v^{0,1} \in \bar{L} \). We see in Proposition 2.17 that the component in \( L \) has no effect on the flow of deformations, therefore we define

\[
\Phi_v := \Phi_{v^{0,1} + \bar{v}^{0,1}},
\]

where \( v^{0,1} + \bar{v}^{0,1} \) is now real. Proposition 2.17 still holds.
3. The infinitesimal case

We would like to make precise and then prove the following rough statement: if \( \varepsilon \) is an infinitesimal deformation of a holomorphic Poisson structure on the closed unit ball \( B_1 \subset \mathbb{C}^n \), then we may construct an infinitesimal flow by a generalized vector field \( V \) which "corrects" the deformation so that it remains within the class of holomorphic Poisson structures. This is a cohomological claim about the complex \( (\wedge^* L^*, d_L) \). When we consider the full problem of finite deformations, this will still be approximately true in some sense, which will help us prove the Main Lemma.

Suppose that \( \varepsilon_t \) is a one-parameter family of deformations of \( L \). Differentiating equation (2.5) by \( t \), we get that

\[
d_L \dot{\varepsilon}_t + [\varepsilon_t, \dot{\varepsilon}_t] = 0
\]

If \( \varepsilon_0 = 0 \), then we have the condition \( d_L \dot{\varepsilon}_0 = 0 \). That is, an infinitesimal deformation of \( L \) must be \( d_L \)-closed.

Thus we make precise the statement in the opening paragraph of this section:

**Proposition 3.1.** Suppose that \( L \) is the \(+i\)-eigenbundle corresponding to a holomorphic Poisson structure \( \beta \) on \( B_1 \subset \mathbb{C}^n \), and suppose that \( \varepsilon \in \Gamma(\wedge^2 L^*) \) satisfies \( d_L \varepsilon = 0 \). Then there exists \( V(\beta, \varepsilon) \in \Gamma(L^*) \) such that \( \varepsilon + d_L V(\beta, \varepsilon) \) has only a bivector component.

**Proof.** As in section 2.2, we write \( \varepsilon = \varepsilon_1 + \varepsilon_2 + \varepsilon_3 \) where the terms are a bivector field, a mixed co- and contravariant term, and a 2-form respectively. The closedness condition, \((\bar{\partial} + d_\beta)\varepsilon = 0 \) (as per Example 2.5), may be decomposed according to the co- and contravariant degree.

For example, we have \( \bar{\partial} \varepsilon_3 = 0 \). Since \( \bar{\partial} \)-cohomology is trivial on the ball \( B_1 \), there exists a \((0,1)\)-form \( P \varepsilon_3 \) such that \( \bar{\partial} P \varepsilon_3 = \varepsilon_3 \). \( -P \varepsilon_3 \) will be one piece of \( V(\beta, \varepsilon) \).

Another component of the closedness condition is \( \bar{\partial} \varepsilon_2 + d_\beta \varepsilon_3 = 0 \). Then

\[
\bar{\partial}(d_\beta P \varepsilon_3 - \varepsilon_2) = \bar{\partial} d_\beta P \varepsilon_3 + d_\beta \bar{\partial} P \varepsilon_3
\]

But \( \bar{\partial} \) and \( d_\beta \) anticommute, so this is 0, i.e., \( d_\beta P \varepsilon_3 - \varepsilon_2 \) is \( \bar{\partial} \)-closed. Therefore it is \( \bar{\partial} \)-exact, and there exists some \((1,0)\)-vector field \( P(d_\beta P \varepsilon_3 - \varepsilon_2) \) such that \( \bar{\partial} P(d_\beta P \varepsilon_3 - \varepsilon_2) = d_\beta P \varepsilon_3 - \varepsilon_2 \). Let

\[
V(\beta, \varepsilon) = P(d_\beta P \varepsilon_3 - \varepsilon_2) - P \varepsilon_3
\]

Then

\[
(\bar{\partial} + d_\beta) V(\beta, \varepsilon) = d_\beta P(d_\beta P \varepsilon_3 - \varepsilon_2) - \varepsilon_2 - \varepsilon_3,
\]

where \( d_\beta P(d_\beta P \varepsilon_3 - \varepsilon_2) \) is a section of \( \wedge^2 T_{1,0} \). Therefore

\[
\varepsilon + d_L V(\beta, \varepsilon) \in \Gamma(\wedge^2 T_{1,0})
\]

\( \square \)

### 3.1. The \( \bar{\partial} \) chain homotopy operator

The non-constructive step in the proof of Proposition 3.1 is the operation \( P \) which gives \( \bar{\partial} \)-primitives for sections of \( (T_{1,0} \otimes T^*_{0,1}) \oplus \wedge^2 T_{0,1}^* \). Fortunately, in [18] Nijenhuis and Woolf give a construction of such an operator and provide norm estimates for it.
Proposition 3.2. For a closed ball $B_r \subset \mathbb{C}^n$, there exists a linear operator $P$ such that for all $i, j \geq 0$,

$$P : \Gamma \left( (\wedge^i T_{1,0}) \otimes (\wedge^{j+1} T_{0,1}^*) \right) \longrightarrow \Gamma \left( (\wedge^i T_{1,0}) \otimes (\wedge^j T_{0,1}^*) \right)$$

such that

$$\bar{\partial} P + P \bar{\partial} = \text{Id},$$

and such that the $C^k$-norms of $P$ satisfies the estimate, for all integers $k \geq 0$,

$$\|P \varepsilon\|_k \leq C \|\varepsilon\|_k.$$

(See Section 5.1 for details on $C^k$ norms.)

We note that $P$ is defined on all smooth sections, not just $\bar{\partial}$-closed sections. But if $\bar{\partial} \varepsilon = 0$, $\bar{\partial} P \varepsilon = \varepsilon$ as desired.

Proof. For a $(0,j)$ form, $P$ is just the operator $T$ defined in [18]. We don’t give the full construction here (or the proofs of its properties), but we remark that it is built inductively from the case of a 1-form $f \bar{\partial} z$ on $\mathbb{C}$, for which

$$(T f \bar{\partial} z)(x) = -\frac{1}{2\pi i} \int_{B_r} f(\zeta) \bar{\partial} \zeta.$$

On the other hand, if $\varepsilon \in \Gamma \left( (\wedge^i T_{1,0}) \otimes (\wedge^{j+1} T_{0,1}^*) \right)$ for $i > 0$, we may write

$$\varepsilon = \sum_I d \frac{\partial}{\partial z_I} \otimes \varepsilon_I,$$

where $I$ ranges over multi-indices, $\frac{\partial}{\partial z_I}$ is the corresponding basis multivector, and $\varepsilon_I \in \Gamma \left( (\wedge^{j+1} T_{0,1}^*) \right)$. Then $T$ is applied to each of the $\varepsilon_I$ individually.

The estimate is also from [18], and by construction of $P$ clearly also applies to mixed co- and contravariant tensors. □

$P$ as defined depends continuously on the radius, $r$, of the polydisc—that is, it doesn’t commute with restriction to a smaller radius. We say no more about this quirk except to note that it is compatible with Theorem 4.17.

3.2. Approximating the finite case with the infinitesimal solution. We sketch how Proposition 3.1 roughly translates to the finite case (for details, see Lemma 6.9):

We will be considering deformations $\varepsilon = \varepsilon_1 + \varepsilon_2 + \varepsilon_3$ of the complex structure on $B_r \subset \mathbb{C}^n$, which are close to being holomorphic Poisson; thus, $\varepsilon_2$ and $\varepsilon_3$ will be small and $\varepsilon_1$ will almost be a holomorphic Poisson bivector. We then pretend that $\varepsilon_2 + \varepsilon_3$ is a small deformation of the almost holomorphic Poisson structure $\beta = \varepsilon_1$, and the argument for Proposition 3.1 goes through approximately. Thus,

Definition 3.3. If $\varepsilon \in \Gamma(\wedge^2 L^*)$, with the decomposition $\varepsilon = \varepsilon_1 + \varepsilon_2 + \varepsilon_3$ as in Section 2.2. Then let

$$V(\varepsilon) = V(\varepsilon_1, \varepsilon_2 + \varepsilon_3) = P([\varepsilon_1, P \varepsilon_3] - \varepsilon_2 - \varepsilon_3).$$

In the above construction, we apply $P$ to sections which are not quite $\bar{\partial}$-closed, so it will not quite yield $\bar{\partial}$-primitives; this error is controlled by equation (3.2). Furthermore, we can no longer say that $[\varepsilon_1, •]$ and $\bar{\partial}$ anticommute; this error will be
controlled by the bialgebroid property (2.4), with \( d_L = \partial \), so that if \( \theta \in \Gamma(\wedge^\bullet L^*) \) then
\[
(3.3) \quad \bar{\partial}[\varepsilon_1, \theta] = -[\varepsilon_1, \bar{\partial}\theta] + [\bar{\partial}\varepsilon_1, \theta].
\]

4. SCI-spaces and the abstract normal form theorem

As discussed in Section 1.2, the local equivalence of a generalized complex structure near a point \( p \) to a holomorphic Poisson structure will be achieved by iteratively applying a particular sequence of local generalized diffeomorphisms to the initial structure, and then arguing that in the limit this sequence takes the initial structure to a holomorphic Poisson structure. A difficulty with this approach is that at each stage we may have to restrict to a smaller neighbourhood of \( p \). Thus the iteration is not in a fixed space of deformations, but rather through a collection of spaces, one for each neighbourhood of \( p \).

The technique for handling this difficulty comes from Conn [6], though we have adopted some of the formalism of Miranda, Monnier and Zung [17] [16], with [16, Sections 6 and 7] our main reference. We adapt the definition of SCI-spaces—or “scaled \( C^\infty \)” spaces—SCI-groups and SCI-actions, with some changes which we discuss. In particular, for simplicity we consider only the “\( C^\infty \)” part of the space (whereas in [16] \( C^k \) sections are considered). Hence, an SCI-space is a radius-parametrized collection of tame Frechet spaces. To be precise:

Definition 4.1. An SCI-space \( \mathcal{H} \) consists of a collection of vector spaces \( \mathcal{H}_r \) with norms \( \| \cdot \|_{k,r} \)—where \( k \geq 0 \) (the smoothness) is in \( \mathbb{Z} \) and \( 0 < r \leq 1 \) (the radius) is in \( \mathbb{R} \)—and for every \( 0 < r' \leq r \leq 1 \) a linear restriction map, \( \pi_{r,r'} : \mathcal{H}_r \to \mathcal{H}_{r'} \).

Furthermore, the following properties should hold:

- If \( r > r' > r'' \) then \( \pi_{r,r''} = \pi_{r,r'} \circ \pi_{r',r''} \).

If \( f \in \mathcal{H}_r \) then, to abuse notation, we denote \( \pi_{r,r'}(f) \in \mathcal{H}_{r'} \) also by \( f \).

- If \( f \in \mathcal{H}_r, r' \leq r \) and \( k' \leq k \), then
  \[
  \|f\|_{k',r'} \leq \|f\|_{k,r},
  \]
  where if neither \( f \) nor a restriction of \( f \) is in \( \mathcal{H}_r \) then we interpret \( \|f\|_r = \infty \). We take as the topology for each \( \mathcal{H}_r \) the one generated by open sets in every norm. We require that

- If a sequence in \( \mathcal{H}_r \) is Cauchy for each norm \( \| \cdot \|_k \) then it converges in \( \mathcal{H}_r \).
- At each radius \( r \) there are smoothing operators, that is, for each real \( t > 1 \) there is a linear map
  \[
  S_r(t) : \mathcal{H}_r \to \mathcal{H}_r
  \]
  such that for any \( p > q \) in \( \mathbb{Z}^+ \) and any \( f \) in \( \mathcal{H}_r \),
  \[
  \|S_r(t)f\|_{p,r} \leq C_{r,p,q} t^{p-q} \|f\|_{q,r}
  \]
  and
  \[
  \|f - S_r(t)f\|_{q,r} \leq C_{r,p,q} t^{q-p} \|f\|_{p,r},
  \]
  where \( C_{r,p,q} \) is a positive constant depending continuously on \( r \).

An SCI-subspace \( S \subset \mathcal{H} \) consists of a collection of subspaces \( S_r \subset \mathcal{H}_r \) which themselves form an SCI-space under the induced norms, restriction maps and smoothing operators. An SCI-subset of \( \mathcal{H} \) consists of a collection of subsets of the \( \mathcal{H}_r \) which is invariant under the restriction maps.
Example 4.2. Let $V$ be a finite-dimensional normed vector space. For each $0 < r \leq 1$, let $B_r \subset \mathbb{R}^n$ or $\mathbb{C}^n$ be the closed unit ball of radius $r$ centred at the origin (under the sup-norm, this is actually a rectangle or polydisc), and let $\mathcal{H}_r$ be the $C^\infty$-sections of the trivial bundle $B_r \times V$, with $\| \cdot \|_{k,r}$ the $C^k$-sup norm. Then the $\mathcal{H}_r$ and $\| \cdot \|_{k,r}$ form an SCI-space.

Remark 4.3. At a fixed radius $r$, $\mathcal{H}_r$ is a tame Frechet space. There are constructions of smoothing operators in many particular instances (see, eg., [11]). The essential point is that $S_r(t)f$ is a smoothing of $f$, in the sense that its higher norms are controlled by lower norms of $f$, and as $t$ gets larger, $S_r(t)f$ is a better approximation to $f$, but is less smooth. As a consequence of the existence of smoothing operators, we have the interpolation inequality (also see [11]):

Proposition 4.4. Let $\mathcal{H}$ be an SCI-space, let $0 \leq l \leq m \leq n$ be integers, and let $r > 0$. Then there is a constant $C_{l,m,n,r} > 0$ such that for any $f \in \mathcal{H}_r$,

$$\|f\|_m^{n-l} \leq C_{l,m,n,r} \|f\|_n^{n-m} \|f\|_l^{m-l}.$$

4.1. Notational conventions. We will need to express norm estimates for members of SCI-spaces, that is, we will write SCI-norms into inequalities. We develop some shorthand for this, which is similar to (but extends) the notation in [16].

Spaces of sections. If $E = B_1 \times V$ is a vector bundle over $B_1 \subset \mathbb{R}^n$ or $\mathbb{C}^n$, then by $\Gamma(E)$ we will always mean the SCI-space of local sections of $E$ near $0 \in \mathbb{C}^n$, as in Example 4.2.

Radius parameters. We will often omit the radius parameter when writing SCI-norms (but we will always include the degree). The right way to interpret such notation is as follows: when the norms appear in an equation, the claim is that this equation holds for any common choice of radius where all terms are well-defined. When the norms appear in an inequality, the claim is that the inequality holds for any common choice of radius $r$ for the lesser side of the inequality, with any common choice of radius $r' \geq r$ for the greater side of the inequality (for which all terms are well-defined).

For example, for $f \in \mathcal{H}$ and $g \in \mathcal{K}$,

$$\|f\|_k \leq \|g\|_{k+1}$$

means

$$\forall 0 < r \leq r' \leq 1, \text{ if } f \in \mathcal{H}_r \text{ and } g \in \mathcal{H}_{r'} \text{ then } \|f\|_{k,r} \leq \|g\|_{k+1,r'}.$$

Remark 4.5. Since the norms are nondecreasing in radius, this convention is plausible.

Constants. Whenever it appears in an inequality, $C$ (or $C'$) will stand for a positive real constant, which may be different in each usage, and which may depend on the degree, $k$, of the terms, and continuously on the radius.

Polynomials. Whenever the notation

$$\text{Poly}(\|f_1\|_{k_1}, \|f_2\|_{k_2}, \ldots)$$

occurs, it denotes some polynomial in $\|f_1\|_{k_1}, \|f_2\|_{k_2}$, etc., with positive coefficients, which may depend on the degrees $k_i$ and continuously on the radius, and which may be different in each usage. These polynomials will always occur as bounds on
the greater side of an inequality, and it will not be important to know their exact form.

**Leibniz polynomials.** Because they occur so often, we give special notation for a certain type of polynomial. Whenever the notation

$$\mathcal{L}(\|f_1\|_{k_1}, \ldots, \|f_d\|_{k_d})$$

occurs it denotes a polynomial (with positive coefficients, which depends on the $k_i$ and continuously on the radius, and which may be different in each usage) such that each monomial term is as follows:

Each $\|f_i\|$ occurs with degree at least 1 (in some norm degree), and at most one of the $\|f_i\|$ has “large” norm degree $k_i$, while the other factors in the monomial have “small” norm degree $\lfloor k_j/2 \rfloor + 1$, where $\lfloor \cdot \rfloor$ denotes the integer part.

Equivalently, using the monotonicity in $k$ of $\| \cdot \|_k$, we can define $\mathcal{L}$ in $\text{Poly}$ notation, as follows:

$$A(f_1, \ldots, f_d) \leq \mathcal{L}(\|f_1\|_{k_1}, \ldots, \|f_d\|_{k_d}) \quad \text{if and only if}$$

$$A(f_1, \ldots, f_d) \leq \sum_{i=1}^{d} \|f_i\|_{k_i} \times \|f_1\|_{\lfloor k_i/2 \rfloor + 1} \times \cdots \times \|f_d\|_{\lfloor k_i/2 \rfloor + 1}$$

$$\times \text{Poly}(\|f_1\|_{\lfloor k_i/2 \rfloor + 1}, \ldots, \|f_d\|_{\lfloor k_i/2 \rfloor + 1}),$$

where $\|f_i\|$ indicates this term is omitted from the product. For example, we might say

$$\|f\|_k \|g\|_{\lfloor k/2 \rfloor + 1} + \|f\|_{\lfloor k/2 \rfloor + 1} \|g\|_{k+1} \|g\|_{\lfloor k/2 \rfloor + 2} \leq \mathcal{L}(\|f\|_k, \|g\|_{k+1}).$$

**Remark 4.6.** A typical example of how such terms arise is: to find the $C^k$-norm of a product of fields, we must differentiate $k$ times, applying the Leibniz rule iteratively. We get a polynomial in derivatives of the fields, and each monomial has at most one factor with more than $\lfloor k/2 \rfloor + 1$ derivatives. See Lemma 6.1 for example, or [11, II.2.2.3] for a sharper estimate.

We extend the definition to allow the entries in a Leibniz polynomial to be polynomials themselves, e.g.,

$$\|f\|_k \|h\|_{\lfloor k/2 \rfloor + 1} + \|f\|_k \|g\|_{\lfloor k/2 \rfloor + 1} \|g\|_{k} \leq \mathcal{L}(\|f\|_k, \|h\|_k + \|g\|_k).$$

In this case, we have used $\|h\|_k + \|g\|_k$ to indicate that not every monomial need have a factor of both $\|g\|$ and $\|h\|$.

**Lemma 4.7.** Leibniz polynomials are closed under composition and addition, e.g.,

$$\mathcal{L}(\mathcal{L}(\|f\|_a, \|g\|_b), \|h\|_c) \leq \mathcal{L}(\|f\|_a, \|g\|_b, \|h\|_c).$$

**Remark 4.8.** The approach in [11] is to study tame maps between tame Frechet spaces. To say that a map is bounded by a Leibniz polynomial in its arguments is similar to the tameness condition. However, rather than adapt this framework to SCI-spaces, we do as in [17] and [16], working directly with bounding polynomials.

**Remark 4.9.** As noted in [17] and elsewhere, whether the coefficients of the polynomials vary continuously with the radius, or do not, makes no difference to the algorithm of Theorem 4.17, which ensures that all radii are between $R/2$ and $R$, over which we can find a radius-independent bound.
SCI-groups. We will give a definition of a group-like structure modelled on SCI-spaces, which is used in [16] to model local diffeomorphisms about a fixed point (and in our case to model local generalized diffeomorphisms); but first we feel we should give a conceptual picture to make the definition clearer:

Elements of an SCI-group will be identified with elements of an SCI-space, and we use the norm structure of the latter to express continuity properties of the former. However, we do not assign any special meaning to the linear structure of the SCI-space—in particular, the SCI model-space for an SCI-group should not be viewed as its Lie algebra in any sense. Furthermore, group elements will be defined at given radii, and their composition may be defined at yet a smaller radius—the amount by which the radius shrinks should be controlled by $\| \cdot \|_1$ of the elements (usually interpreted as a bound on their first derivative) and a fixed parameter for the group.

Definition 4.10. An SCI-group $G$ modelled on an SCI-space $W$ consists of elements which are formal sums

$$\varphi = \text{Id} + \chi,$$

where $\chi \in W$, together with a scaled product defined for some pairs in $G$, i.e.:

There is a constant $c > 1$ such that if $\varphi$ and $\psi$ are in $G_r$ for some $r$ and

$$\| \varphi - \text{Id} \|_{1,r} \leq 1/c,$$

then,

(a) the product $\psi \cdot \varphi \in G_{r'}$ is defined, where $r' = r(1 - c\| \varphi - \text{Id} \|_{1,r})$; furthermore, the product operation commutes with restriction, and is associative modulo necessary restrictions, and

(b) there exists a scaled inverse $\varphi^{-1} \in G_{r''}$ such that $\varphi \cdot \varphi^{-1} = \varphi^{-1} \cdot \varphi = \text{Id}$ at radius $r'' = r'(1 - c\| \varphi - \text{Id} \|_{1,r})$.

Furthermore, for $k \geq 1$ the following continuity conditions should hold:

$$\| \psi^{-1} \varphi^{-1} \|_k \leq \mathcal{L}(\| \psi - \varphi \|_k, 1 + \| \varphi - \text{Id} \|_k),$$

$$\| \varphi \cdot \psi - \varphi \|_k \leq \mathcal{L}(\| \psi - \text{Id} \|_k, 1 + \| \varphi - \text{Id} \|_{k+1}),$$

$$\| \varphi \cdot \psi - \text{Id} \|_k \leq \mathcal{L}(\| \psi - \text{Id} \|_k + \| \varphi - \text{Id} \|_k).$$

(As per the notational convention, these inequalities are taken at precisely those radii for which they make sense.)

Example 4.11. As in Example 4.2, for each $0 < r \leq 1$ let $B_r \subset \mathbb{R}^n$ be the closed unit ball of radius $r$ centred at the origin, and let $W_r$ be the space of $C^\infty$-maps from $B_r$ into $\mathbb{R}^n$ fixing the origin. If $\chi$ is such a map, then by $\varphi = \text{Id} + \chi$ we mean the sum of $\chi$ with the identity map; then $\text{Id} + W_r$ forms an SCI-group under composition for some constant $c > 1$. These are the local diffeomorphisms. (See Lemma 5.6 and [6] for details.)

Remark 4.12. Our definition of SCI-group is a bit different than that appearing in [16]. Our continuity conditions look different—though, ignoring terms of norm degree $[k/2] + 1$, our conditions imply those in [16]. (See Remark 4.19.)

Definition 4.13. A left (resp. right) SCI-action of an SCI-group $G$ on an SCI-space $H$ consists of an operation $\varphi \cdot f \in H_{r'}$ for $\varphi \in G_{r'}$ and $f \in H_r$, which is defined whenever $r' \leq (1 - c\| \varphi - \text{Id} \|_{1,r})r$ for some constant $c > 1$, such that the following hold: the operation should commute with radius restriction, it should satisfy the
usual left (resp. right) action law modulo radius restriction, and there should be some $s$ (called the derivative loss) such that, for large enough $k$, for $\varphi, \psi \in G_r$ and $f, g \in H_r$, the following continuity conditions hold:

\begin{align}
\| \varphi \cdot f - \varphi \cdot g \|_k & \leq \mathcal{L}(\| f - g \|_k, 1 + \| \varphi - \text{Id} \|_{k+s}) \quad \text{and} \\
\| \psi \cdot f - \varphi \cdot f \|_k & \leq \mathcal{L}(1 + \| f \|_{k+s}, \| \psi - \varphi \|_{k+s}, 1 + \| \varphi - \text{Id} \|_{k+s}),
\end{align}

(f these terms are well-defined).

Remark 4.14. (4.8) will ensure that if a sequence $\varphi_1, \varphi_2, \ldots$ converges, then so does $\varphi_1 \cdot f, \varphi_2 \cdot f, \ldots$. Combining (4.7) with (4.8) for $f = 0$ and $\psi = \text{Id}$, we get

\begin{equation}
\| \varphi \cdot g \|_k \leq \mathcal{L}(\| g \|_k, \| \varphi - \text{Id} \|_{k+s})
\end{equation}

Remark 4.15. If the action is linear, we may equivalently simplify the hypotheses: we may discard $g$ entirely in (4.7), and, since each term will be first order in norms of $f$, we may replace $1 + \| f \|_k$ with $\| f \|_k$ in (4.8); furthermore, in both estimates the polynomials will not have higher powers of $\| f \|$. In [16], our source for Theorem 4.17, only linear (and, in some sense, affine) SCI-actions are considered.

Even considering this difference, our definition is a bit stronger than in [16]—as per our definition of Leibniz polynomials, $\mathcal{L}$, we do not permit more than one factor of high norm degree in each monomial.

Example 4.16. The principal example of SCI-actions are local diffeomorphisms (Example 4.11) acting by pushforward or pullback on tensors, with derivative loss $s = 1$. See Section 5.2 for details.

4.2. Abstract normal form theorem. The following theorem is adapted from [16, Thm. 6.8], with some changes. The idea of applying the Nash-Moser fast convergence method to shrinking neighbourhoods of a point goes back to Conn’s work in [6]. After the statement of the theorem, we give the interpretation of each SCI-space and map named in the theorem, as it applies to our situation, and show how the theorem may be used to prove our Main Lemma. Then we address the differences between the theorem as we have presented it and as it appears in [16]. A similar theorem is in [17].

Theorem 4.17. [MMZ] Let $T$ be an SCI-space, $\mathcal{F}$ an SCI-subspace of $T$, and $I$ a subset of $T$ containing 0. Denote $\mathcal{N} = \mathcal{F} \cap I$. Let $\pi : T \rightarrow \mathcal{F}$ be a projection commuting with restriction and inclusion, and let $\zeta = \text{Id} - \pi$. Suppose that, for all $\varepsilon \in T$, and all $k \in \mathbb{N}$ sufficiently large,

\begin{equation}
\| \zeta(\varepsilon) \|_k \leq \mathcal{L}(\| \varepsilon \|_k).
\end{equation}

Let $G$ be an SCI-group acting on $T$, and let $G^0 \subset G$ be a closed subset of $G$ preserving $I$.

Let $V$ be an SCI-space. Suppose there exist maps

\begin{align*}
I & \xrightarrow{V} V \\
& \xrightarrow{G} G^0
\end{align*}
(with $\Phi(v)$ denoted $\Phi_v$) and $s \in \mathbb{N}$ such that, for every $\varepsilon \in \mathcal{I}$, every $v, w \in \mathcal{V}$, and for large enough $k$,

$$\|V(\varepsilon)\|_k \leq \mathcal{L}(\|\zeta(\varepsilon)\|_{k+s}, 1 + \|\varepsilon\|_{k+s})$$

(4.11)

$$\|\Phi_v - Id\|_k \leq \mathcal{L}(\|v\|_{k+s}), \quad \text{and}$$

$$\|\Phi_v \cdot \varepsilon - \Phi_w \cdot \varepsilon\|_k \leq \mathcal{L}(\|v - w\|_{k+s}, 1 + \|v\|_{k+s} + \|w\|_{k+s} + \|\varepsilon\|_{k+s})$$

(4.12)

$$+ \mathcal{L}((\|v\|_{k+s} + \|w\|_{k+s})^2, 1 + \|\varepsilon\|_{k+s})$$

(4.13)

Finally, suppose there is a real positive $\delta$ such that for any $\varepsilon \in \mathcal{I}$,

$$\|\zeta(\Phi_{V(\varepsilon) \cdot \varepsilon})\|_k \leq \|\zeta(\varepsilon)\|_k^{1+\delta} \text{Poly}(\|\varepsilon\|_{k+s}, \|\Phi_{V(\varepsilon) - Id}\|_{k+s}, \|\zeta(\varepsilon)\|_{k+s}, \|\varepsilon\|_k)$$

(4.14)

where in this case the degree of the polynomial in $\|\varepsilon\|_{k+s}$ does not depend on $k$.

Then there exist $l \in \mathbb{N}$ and two constants $\alpha > 0$ and $\beta > 0$ with the following property: if $\varepsilon \in \mathcal{I}_R$ such that $\|\varepsilon\|_{2l-1,R} < \alpha$ and $\|\zeta(\varepsilon)\|_{l,R} < \beta$, there exists $\psi \in \mathcal{G}_R^{0}$ such that $\psi \cdot \varepsilon \in \mathcal{N}_{R/2}$.

Remark 4.18. In our case, the interpretation of the terms in this theorem will be as follows:

- $\mathcal{T}$ will be the space of deformations, $\Gamma(\wedge^2 L^*)$, of the standard generalized complex structure on $\mathbb{C}^n$.
- $\mathcal{F} \subset \mathcal{T}$ will be the space of $(2,0)$-bivectors, the “normal forms” without the integrability condition—thus $\zeta(\varepsilon) = \varepsilon_2 + \varepsilon_3$ is the non-bivector part of $\varepsilon$, which we seek to eliminate.
- $\mathcal{I}$ will be the integrable deformations, and thus $\mathcal{N} = \mathcal{F} \cap \mathcal{I}$ will be the holomorphic Poisson bivectors, i.e., the “normal forms.”
- $V$ produces a generalized vector field from a deformation. As per Definition 3.3, we will take $V(\varepsilon) = P(\varepsilon_1, P\varepsilon_3 - \varepsilon_2 - \varepsilon_3)$.
- $\mathcal{G} = \mathcal{G}^0$ will be the local generalized diffeomorphisms fixing the origin, acting on deformations as in Definition 2.11, and $\Phi_v \in \mathcal{G}$ will be the time-1 flow of the generalized vector field $v$ as in Definition 2.13.

While estimates (4.10) through (4.13) in the hypotheses of the theorem may be understood as continuity conditions of some sort, estimate (4.14) expresses the fact that we have the “correct” algorithm, that is, each iteration will have a quadratically small error.

4.3. Proving the Main Lemma. In Section 5 we verify that local generalized diffeomorphisms form a closed SCI-group, and that they act by SCI-action on the deformations. In Section 6 we show that the other hypotheses of Theorem 4.17, estimates (4.10) through (4.14), hold true for the interpretation above. Thus, the theorem applies, and we conclude the following: if $\varepsilon$ is a smooth, integrable deformation of the standard generalized complex structure in a neighbourhood of the origin in $\mathbb{C}^n$, and if $\|\varepsilon\|_k$ is small enough (for some $k$ given by the theorem), then there is a local generalized diffeomorphism $\Psi$ fixing the origin such that $\zeta(\Psi \cdot \varepsilon) = 0$.

Then the Maurer-Cartan equations (2.6) and (2.7) tell us that $\Psi \cdot \varepsilon$ is a holomorphic Poisson bivector, and thus the Main Lemma is proved.

4.4. Sketch of the proof of Theorem 4.17. The proof of Theorem 4.17 is essentially in [16, Appendix 1], with the idea of the argument coming from [6]. Rather than give a full proof of our version, for the reader who wishes to verify in detail,
we give a rough sketch of the argument as it appears in [16] and, in Remark 4.19, we justify the changes we have made from [16].

We are given \( \varepsilon = \varepsilon^0 \in \mathcal{S}_R \) and will construct a sequence \( \varepsilon^1, \varepsilon^2, \ldots \). We choose a sequence of smoothing parameters \( t_d \), with \( t_0 > 1 \) (determined by the requirements of the proof) and \( t_{d+1} = t_d^{3/2} \). Then for \( d > 0 \) let \( t_d = S_{t_d} V(\varepsilon^d) \), where \( S_{t_d} \) is the smoothing operator, let \( \Phi_{d+1} = \Phi_{t_d} \), and let \( \varepsilon^{d+1} = \Phi_{d+1} \cdot \varepsilon^d \). The \( V(\varepsilon^d) \) is smoothed before taking \( \Phi_{d+1} \) so that we have some control over the loss of derivatives at each stage.

If \( \|\varepsilon\|_{2l-1} \) and \( \|\zeta(\varepsilon)\|_l \) are small enough, for certain \( l \), and if \( t_0 \) is chosen carefully, then it will follow that the \( \|\Phi_{d}\|_k \) approach zero quickly and the corresponding radii have lower bound \( R/2 \); by continuity properties of SCI-groups and \( - \)actions, the compositions \( \Psi_{d+1} = \Phi_{d+1} \cdot \Psi_d \) will have a limit, \( \Psi_{\infty} \), and the \( \varepsilon^d \) will have a limit, \( \varepsilon^\infty = \Psi_{\infty} \cdot \varepsilon \). Furthermore, it will follow that \( \zeta(\varepsilon^\infty) = \lim \zeta(\varepsilon^d) = 0 \), so \( \varepsilon^\infty \in \mathcal{N} \).

The above facts follow from two inductive lemmas. The first fixes a norm degree, \( l \), and an exponent, \( A > 1 \), (determined by requirements of the proof) and proves inductively that for all \( d \geq 0 \),

\[
\begin{align*}
(1_d) & \quad \|\Phi^{d+1} - \text{Id}\|_{l+s} < t_d^{-1/2} \\
(2_d) & \quad \|\varepsilon^d\|_l < C d^{1/2} \\
(3_d) & \quad \|\varepsilon^d\|_{2l-1} < t_d^A \\
(4_d) & \quad \|\zeta(\varepsilon^d)\|_{2l-1} < t_d^A \\
(5_d) & \quad \|\zeta(\varepsilon^d)\|_l < t_d^{-1} \\
\end{align*}
\]

The second lemma uses the first to prove by induction on \( k \) that, for all \( k \geq l \), there is \( d_k \) large enough such that for all \( d \geq d_k \),

\[
\begin{align*}
(i) & \quad \|\Phi^{d+1} - \text{Id}\|_{k+s+1} < C k t_d^{-1/2} \\
(ii) & \quad \|\varepsilon^d\|_{k+1} < C k t_d^{1/2} \\
(iii) & \quad \|\varepsilon^d\|_{2k-1} < C k t_d^A \\
(iv) & \quad \|\zeta(\varepsilon^d)\|_{2k-1} < C k t_d^A \\
(v) & \quad \|\zeta(\varepsilon^d)\|_k < C k t_d^{-1} \\
\end{align*}
\]

Given this setup, the proofs simply proceed in order through \( 1_d, \ldots, 5_d, i \ldots, iv \) by application of the hypotheses of Theorem 4.17, the continuity conditions for SCI-groups and SCI-actions, and the property of the smoothing operators.

**Remark 4.19.** The differences between the theorem as we have presented it and as it appears in [16] include notational and other minor changes, which we do not remark upon, and changes to the estimates coming from the nonlinearity of our action, which we now justify, with reference to [16, Sections 6.2 and 7]:

First we remark that, for the SCI definitions and for the hypotheses of the abstract normal form theorem, our estimates imply theirs if any instance of \( \|\varepsilon\|_p \), \( \|\zeta(\varepsilon)\|_p \) or \( \|\Phi - \text{Id}\|_p \) in [16] is replaced with the nonlinear \( \mathcal{L}(1 + \|\varepsilon\|_p) \), \( \mathcal{L}(\|\zeta(\varepsilon)\|_p) \) or \( \mathcal{L}(\|\Phi - \text{Id}\|_p) \) respectively. That is, in several instances their estimates require that the bound be linear in one of the above quantities, whereas we have allowed extra factors of \( \|\cdot\|_{p/2}^{1/2} \); furthermore, we have allowed certain extra terms which are zero-order in \( \|\varepsilon\|_p \).

But this is not a problem—the estimates are *locally equivalent* (we will be precise), and thus are valid over the sequence defined above. To see why, we note that, as stated in the sketch of the proof above, in the two subsidiary lemmas, \( \|\varepsilon^d\|_p \) only
appears with \( p \leq 2l - 1 \) in the first lemma or \( p \leq 2k - 1 \) in the second. But then
\[
\mathfrak{L}(1 + \|\varepsilon^d\|_p) = (1 + \|\varepsilon\|_p) \text{Poly}(\|\varepsilon^d\|_{[p/2]+1}) \leq (1 + \|\varepsilon\|_p) \text{Poly}(\|\varepsilon^d\|_l)
\]
(and respectively for \( k \).) But the inductive hypothesis has that \( \|\varepsilon^d\|_l \) (resp. \( \|\varepsilon^d\|_k \)) is bounded by a constant, so this extra polynomial factor does no harm. Similarly, the extra factors in \( \mathfrak{L}(\|\zeta(\varepsilon^d)\|_p) \) and \( \mathfrak{L}(\|\Phi^d - \text{Id}\|_p) \) are vanishingly small by the inductive hypothesis.

The remaining concern, then, is for \( 1 + \|\varepsilon\|_p \) in place of \( \|\varepsilon\|_p \). This is already dealt with implicitly in the affine version of the theorem in [16]: the space \( T \) may be embedded affinely in \( \mathbb{C} \oplus T \), by \( \varepsilon \mapsto (1, \varepsilon) \), with the norm \( \| (1, \varepsilon) \|_p = 1 + \|\varepsilon\|_p \).

The constraint \( \alpha \) in the hypothesis, \( \|\varepsilon\|_2^{l-1} \leq \alpha \), in the original theorem can always be chosen greater than 1, so in the affine context we simply require that \( \|\varepsilon\|_2^{l-1} \leq \alpha' = \alpha - 1 \).

5. Verifying the SCI estimates

In this section we explain how the particular objects named in Remark 4.18 satisfy the SCI definitions.

5.1. Norms. Throughout this paper we will use various kinds of \( C^k \) sup-norms.

**Definition 5.1.** Let \( X \in \mathbb{R}^q \) or \( \mathbb{C}^q \). \( X_i \) is the \( i \)-th component. Then let
\[
\|X\| = \sup_i |X_i|.
\]
Similarly, if \( A = [a_{ij}] \) is an \( n \times n \) matrix, let \( \|A\| = \sup_{i,j} |a_{ij}| \).

**Remark 5.2.** Comparing our matrix norm to the operator norm \( \| \cdot \|_{\text{op}} \), we have
\[
\|A\| \leq \|A\|_{\text{op}} \leq n \|A\|.
\]
Then if \( \|A - \text{Id}\| \leq \frac{1}{2n} \), \( A \) is invertible and
\[
\|A^{-1}\| \leq 2.
\]

**Definition 5.3.** Suppose now that \( f \) is a vector-valued function, \( f : U \to V \), where \( U \subset \mathbb{R}^n \) or \( \mathbb{C}^n \) and \( V \) is a normed finite-dimensional vector space. Then let
\[
\|f\|_0 = \sup_{x \in U} \|X(x)\|.
\]
Suppose furthermore that \( f \) is smooth. If \( \alpha \) is a multi-index, then \( f^{(\alpha)} \) is the corresponding higher-order partial derivative. If \( k \) is a non-negative integer, then \( f^{(k)} \) is an array containing the terms \( f^{(\alpha)} \) for \( |\alpha| = k \). Let
\[
\|f\|_k = \sup_{|\alpha| \leq k} \|f^{(\alpha)}\|_0 = \sup_{j \leq k} \|f^{(k)}\|_0.
\]

**Remark 5.4.** Ultimately, we will always be working over the manifold \( \mathbb{C}^n \) or a subset thereof. Using the standard trivialization of the tangent and cotangent bundles, Definitions 5.1 and 5.3 give us a nondecreasing family of norms, \( \| \cdot \|_k \), on smooth, \( C^\infty \)-bounded tensor fields on subsets of \( \mathbb{C}^n \). This applies to generalized vector fields, \( B \)-fields, and higher rank tensors (including deformations in \( \wedge^2 L^* \)). However, for technical reasons, we must use a slightly unusual norm for Courant automorphisms:
Definition 5.5. If $\Phi = (B, \varphi)$ is a Courant automorphism over a subset of $\mathbb{C}^n$, then we usually only take norms of $\Phi - \text{Id} = (B, \varphi - \text{Id})$. Considering $\varphi - \text{Id}$ as just a function from a subset of $\mathbb{C}^n$ to $\mathbb{C}^n$, let $\|\Phi - \text{Id}\|_0 = \sup(\|B\|_0, \|\varphi - \text{Id}\|_0)$; but if $k \geq 1$, then let

$$\|\Phi - \text{Id}\|_k = \sup(\|B\|_{k-1}, \|\varphi - \text{Id}\|_k).$$

The difference in degree between $B$ and $\varphi$ reflects the fact that $B$ acts on derivatives while $\varphi$ acts on the underlying points of the manifold.

5.2. Pushforwards and pullbacks. As mentioned in Examples 4.11 and 4.16,

Lemma 5.6. Local diffeomorphisms from the closed balls $B_r \subset \mathbb{R}^n$ to $\mathbb{R}^n$ fixing the origin form an SCI-group under composition (see Example 4.11) with constant $c = 2n$. Furthermore, the pullback action, $\varphi^* f = f \circ \varphi$, of a local diffeomorphism $\varphi$ on a function $f : B_r \to \mathbb{C}^p$, is a right SCI-action, with derivative loss $s = 1$.

As we said earlier, the continuity estimates in our definitions of SCI-group and SCI-action are slightly different from [16]: for SCI-groups, (4.4) is stronger, and (4.5) and (4.6) have the same first-order behaviour in each group element, while having possibly higher-order terms (but only in $|k/2| + 1$ norms). For SCI-actions, (4.7) and (4.8) are nonlinear counterparts to the conditions in [16].

Proof. The proof of Lemma 5.6, including the existence of compositions and inverses at the correct radii and the various continuity estimates, is essentially in [6] (and [17], with minor differences as noted). We show only the proof of (4.4)—the SCI-group continuity estimate for inverses—since it gives the flavour of the proofs of the other estimates, and differs most significantly from [16].

Let $\varphi$ and $\psi$ be local diffeomorphisms. We proceed by induction on the degree of the norm. If $\alpha = (\alpha_1, \ldots, \alpha_n)$ is a multi-index, we denote the $\alpha$-order partial derivative $D_\alpha$. Suppose that (4.4) holds for degree less than $k$, that is, whenever $|\alpha| < k$,

$$\|D_\alpha(\varphi^{-1} - \psi^{-1})\|_0 \leq \mathcal{L}(\|\varphi - \psi\|_{|\alpha|}, 1 + \|\psi - \text{Id}\|_{|\alpha|}).$$

(This certainly holds for $|\alpha| = 0$, given the hypothesis that $\|\varphi - \text{Id}\|_1 \leq 1/2n$ and likewise for $\psi$.)

Now suppose that $|\alpha| = k$. We have the trivial identity

$$(5.2) \quad 0 = D_\alpha ((\varphi - \psi) \circ \varphi^{-1}) + D_\alpha (\psi \circ \varphi^{-1} - \psi \circ \psi^{-1})$$

To compute the derivative $D_\alpha(\psi \circ \varphi^{-1} - \psi \circ \psi^{-1})$ at $x \in B_r$, we make repeated applications of the chain rule and Leibniz rule, so that we have a sum of terms each of which has the form, for some $|\beta| \leq |\alpha|$,

$$(5.3) \quad D_\beta \psi|_{\varphi^{-1}(x)} \cdot Q_\beta (\varphi^{-1}) \big|_x - D_\beta \psi|_{\psi^{-1}(x)} \cdot Q_\beta (\psi^{-1}) \big|_x,$$

where $Q_\beta(\varphi^{-1})$ is a polynomial expression in derivatives of $\varphi^{-1}$ up to order $|\alpha| + 1 - |\beta|$ (and likewise for $Q_\beta(\psi^{-1})$). We remark that each term like (5.3) will have at most one factor with higher derivatives than $|k/2| + 1$. Equivalently, (5.3) is

$$D_\beta \psi|_{\varphi^{-1}(x)} \cdot (Q_\beta(\varphi^{-1}) - Q_\beta(\psi^{-1})) \big|_x + D_\beta(\psi|_{\varphi^{-1}(x)} - \psi|_{\psi^{-1}(x)}) \cdot Q_\beta (\varphi^{-1}) \big|_x$$

When $|\beta| = 1$, this is, for some $i$,

$$(5.4) \quad \frac{\partial}{\partial x_i} \psi|_{\varphi^{-1}(x)} : D_\alpha(\varphi^{-1} - \psi^{-1})|_x + D_\beta(\psi|_{\varphi^{-1}(x)} - \psi|_{\psi^{-1}(x)}) \cdot D_\alpha \varphi^{-1}|_x.$$
Thus, we may solve (5.2) for \( D_\alpha (\varphi^{-1} - \psi^{-1})|_x \) as follows: we collect all terms like the first term in (5.4), then by inverting the matrix \( a_{ij} = \left. \frac{\partial}{\partial x_i} \psi_j \right|_{\psi^{-1}(x)} \) and applying it to (5.2), we see that the result will be \( D_\alpha (\varphi^{-1} - \psi^{-1})|_x \) plus some other terms, each of which will be built from the following factors:

- a matrix inverse whose norm is bounded by 2
  
  \[
  \left\| \left. \frac{\partial}{\partial x_i} \psi_j \right|_{\psi^{-1}(x)} - \text{Id} \right\| \leq \frac{1}{2n},
  \]

- derivatives of \( \psi \) up to order \( k \),
- derivatives of \( \varphi^{-1} - \psi^{-1} \) up to order \( k - 1 \),
- derivatives of \( \varphi - \psi \) up to order \( k \),
- derivatives of \( \varphi^{-1} \) up to order \( k \),

What if we compute the norm of this solution for \( D_\alpha (\varphi^{-1} - \psi^{-1})|_x \)? In the special case where \( \varphi = \text{Id} \), by applying the induction hypothesis and combining the Leibniz polynomials we obtain that

\[
\left\| \psi^{-1} - \text{Id} \right\|_k \leq L \left( \left\| \psi - \text{Id} \right\|_k \right).
\]

Returning to the general case, this gives us the bound on \( \left\| \varphi^{-1} - \text{Id} \right\|_k \) that we need to complete the proof. \( \square \)

**Lemma 5.7.** Let \( E = B_r \times V \) be a trivial rank-\( n \) vector bundle over the closed ball \( B_r \subset \mathbb{C}^n \), for each \( 0 < r \leq 1 \). Then the the vector bundle automorphisms covering the identity, \( \text{Aut}(E) \), form an SCI-group with constant \( c = 2n \), and act by SCI-action on the sections, \( \Gamma(E) \), with derivative loss \( s = 0 \).

If \( \text{Aut}(E) \) and \( \Gamma(E) \) are treated as matrix- and vector-valued functions respectively, then the necessary estimates follow in a straightforward way from applications of the product rule, as in Remark 4.6, using Remark 5.2 for the inverse estimate (4.4).

The following lemma tells us that an action will be SCI if it is composed of SCI-actions in a certain sense. In fact, we don’t use any of the algebraic structure of actions.

**Lemma 5.8.** Let \( A, B, G \) and \( H \) be SCI-spaces, where \( A, B \) and \( G \) each have a distinguished element \( \text{Id} \), let

\[
\cdot : A \times H \rightarrow H \quad \text{and} \quad \cdot : B \times H \rightarrow H
\]

be operations satisfying estimates (4.7) and (4.8) with derivative loss \( s_1 \) and \( s_2 \) respectively (no other SCI-action structure is assumed), and let

\[
\cdot : G \times H \rightarrow H
\]

be an operation such that, for each \( \varphi \in G \) there are \( \varphi_A \in A \) and \( \varphi_B \in B \) (with \( \text{Id}_A = \text{Id} \) and \( \text{Id}_B = \text{Id} \)) such that for each \( h \in H \),

\[
\varphi \cdot h = \varphi_A \cdot (\varphi_B \cdot h).
\]

Finally, suppose there is an \( s_3 \) such that for any \( \varphi, \psi \in G \) and large enough \( k \),

\[
\|\varphi_A - \psi_A\|_k \leq L(\|\varphi - \psi\|_{k+s_3}) \quad \text{and} \quad \|\varphi_B - \psi_B\|_k \leq L(\|\varphi - \psi\|_{k+s_3}).
\]

Then the operation of \( G \) on \( H \) also satisfies estimates (4.7) and (4.8) with derivative loss \( s_1 + s_2 + s_3 \).
Proof. If \( \varphi \in \mathcal{G} \) and \( f, g \in \mathcal{H} \), we apply estimate (4.7) for the actions of \( \mathcal{A} \) and \( \mathcal{B} \):
\[
\| \varphi \cdot f - \varphi \cdot g \|_k = \| \varphi_A \cdot (\varphi_B \cdot f) - \varphi_A \cdot (\varphi_B \cdot g) \|_k \\
\leq \mathcal{L}(\| \varphi_B \cdot f - \varphi_B \cdot g \|_k, 1 + \| \varphi_A - \text{Id} \|_{k+s_1}) \\
\leq \mathcal{L}(\mathcal{L}(\| f - g \|_k, 1 + \| \varphi_B - \text{Id} \|_{k+s_1}), 1 + \| \varphi_A - \text{Id} \|_{k+s_1})
\]
Composing the Leibniz polynomials and using (5.5) for \( \| \varphi_A - \text{Id} \| \) and \( \| \varphi_B - \text{Id} \| \), we see that estimate (4.7) holds for the action of \( \mathcal{G} \), with derivative loss \( s_1 + s_3 \).

If \( \varphi, \psi \in \mathcal{G} \) and \( f \in \mathcal{H} \), then
\[
\| \psi \cdot f - \varphi \cdot f \|_k = \| \psi_A \cdot (\psi_B \cdot f) - \varphi_A \cdot (\varphi_B \cdot f) \|_k \\
\leq \| \psi_A \cdot (\psi_B \cdot f) - \varphi_A \cdot (\psi_B \cdot f) \|_k \\
+ \| \varphi_A \cdot (\psi_B \cdot f) - \varphi_A \cdot (\varphi_B \cdot f) \|_k.
\]
Similarly to above, we apply estimate (4.8) to line (5.6) and estimate (4.7) to line (5.7), and then vice versa, followed by the estimates (5.5), and we see that (4.8) holds for the action of \( \mathcal{G} \), with total derivative loss \( s_1 + s_2 + s_3 \). □

Lemma 5.9. The action of local diffeomorphisms by pushforward or by pullback on tensors constitutes an SCI-action with derivative loss \( s = 1 \).

Proof. If \( \varphi : B_r \to \mathbb{R}^n \) is a local diffeomorphism with \( \| \varphi - \text{Id} \|_1 \leq 1/2n \) and \( v : B_r \to TB_r \simeq B_r \times \mathbb{R}^n \) is a vector field, then the pushforward of \( v \) by \( \varphi \) may be decomposed as
\[
\varphi_* v = (D\varphi \cdot v) \circ \varphi^{-1},
\]
where the derivative \( D\varphi \) is treated as a matrix-valued function, acting on \( v \) by fibrewise multiplication. Similarly, if \( \theta : B_r \to T^*B_r \simeq B_r \times \mathbb{R}^n \) is a 1-form, then the pushforward of \( \theta \) may be written
\[
\varphi_* \theta = ((D\varphi^T)^{-1} \cdot \theta) \circ \varphi^{-1},
\]
where the \((D\varphi^T)^{-1}\) is the matrix transpose and inverse at each point. We may regard \( D\varphi \cdot v \) and \((D\varphi^T)^{-1} \cdot \theta\) as functions from \( B_r \) to \( \mathbb{R}^n \), in which case precomposition by \( \varphi^{-1} \) acts by SCI-action with derivative loss \( s = 1 \); and \( D\varphi \) and \((D\varphi^T)^{-1}\) are automorphisms of the vector bundle \( B_r \times \mathbb{R}^n \), and thus act by SCI-action with derivative loss \( s = 0 \). If \( \psi \) is another local diffeomorphism then
\[
\| D\psi - D\varphi \|_{k-1} \leq \| \psi - \varphi \|_k,
\]
and
\[
\| (D\psi^T)^{-1} - (D\varphi^T)^{-1} \|_{k-1} \leq \mathcal{L}(\| D\psi - D\varphi \|_{k-1}),
\]
so by taking a degree-shifted norm on the \( D\psi - D\varphi \), we are in the case of Lemma 5.8.

A similar argument works for pullbacks, and for higher-rank tensors. □

5.3. Estimates of Courant actions.

Lemma 5.10. Local generalized diffeomorphisms on the balls \( B_r \subset \mathbb{C}^n \) form an SCI-group.

Proof. Recall (Definition 2.8) that a local generalized diffeomorphism \( \Phi \) may be represented \((B, \varphi)\), where \( B \) is a closed 2-form and \( \varphi \) is a local diffeomorphism. If \( \Psi = (B', \psi) \) is another local generalized diffeomorphism, then
\[
\Phi \circ \Psi = (\psi^* B + B', \varphi \circ \psi) \quad \text{and} \quad \Phi^{-1} = (-\varphi^{-1})^* B, \varphi^{-1}.
\]
We already know that local diffeomorphisms form an SCI-group, and
\[ r(1 - c\|\Phi - \text{Id}\|_{1,r}) \leq r(1 - c\|\varphi - \text{Id}\|_{1,r}), \]
thus products and inverses exist at precisely the radii required in the definition. Furthermore, estimates (4.4), (4.5) and (4.6) will be satisfied for the diffeomorphism term, thus we only need to check them for the \(B\)-field term.

We first bound \(\Phi^{-1} - \Psi^{-1}\) (estimate (4.4)). Recall that the norm degree is shifted for the \(B\)-field term. Since pushforward is an SCI-action with derivative loss 1, we may use the continuity estimates for SCI-actions:
\[
\|((\varphi^{-1})^* B - (\psi^{-1})^* B')_{k-1} = \|\varphi_* B - \psi_* B'\|_{k-1} \\
\leq \|\varphi_* B - \varphi_* B'\|_{k-1} + \|\psi_* B' - \psi_* B'\|_{k-1} \\
\leq \mathcal{L}(\|B - B'\|_{k-1}, 1 + \|\varphi - \text{Id}\|_{k}) + \mathcal{L}(\|B'\|_{k}, \|\varphi - \psi\|_{k}, \|\psi - \text{Id}\|_{k}) \\
\leq \mathcal{L}(\|\Phi - \Psi\|_{k}, 1 + \|\Phi - \text{Id}\|_{k}) + \mathcal{L}(\|\Psi - \text{Id}\|_{k+1}, \|\Phi - \Psi\|_{k}, \|\Psi - \text{Id}\|_{k})
\]
We use \(1 + \|\Phi - \text{Id}\|_{k} \leq 1 + \|\Psi - \text{Id}\|_{k} + \|\Phi - \Psi\|_{k}\) and combine the Leibniz polynomials to get estimate (4.4).

Now we bound \(\Phi \circ \Psi - \Phi\) (estimate (4.5)). We use estimate (4.8) for pullbacks on the second line:
\[
\|\psi^* B + B' - B\|_{k-1} \leq \|\psi^* B - B\|_{k-1} + \|B'\|_{k-1} \\
\leq \mathcal{L}(1 + \|B\|_{k}, \|\psi - \text{Id}\|_{k}) + \|B'\|_{k-1} \\
\leq \mathcal{L}(1 + \|\Phi - \text{Id}\|_{k+1}, \|\Psi - \text{Id}\|_{k}) + \mathcal{L}(\|\Psi - \text{Id}\|_{k}, \|\Phi - \text{Id}\|_{k})
\]
Finally, we bound \(\Phi \circ \Psi - \text{Id}\) (estimate (4.6)). We use estimate (4.7) on the second line:
\[
\|\psi^* B + B' - \text{Id}\|_{k-1} \leq \|\psi^* B\|_{k-1} + \|B'\|_{k-1} \\
\leq \mathcal{L}(1 + \|\psi - \text{Id}\|_{k}, \|B\|_{k-1}) + \|B'\|_{k-1} \\
\leq \mathcal{L}(1 + \|\Psi - \text{Id}\|_{k}, \|\Phi - \text{Id}\|_{k}) + \|\Psi - \text{Id}\|_{k}
\]
and the result follows. \(\square\)

**Remark 5.11.** Regarding closedness, we consider a \(C^\infty\)-convergent sequence of local generalized diffeomorphisms,
\[
\lim_{n \to \infty} (B_n, \varphi_n) = (\lim_{n \to \infty} B_n, \lim_{n \to \infty} \varphi_n) = (B, \varphi).
\]
Since local diffeomorphisms are closed, \(\varphi\) is a local diffeomorphism; if each \(dB_n = 0\) then, since the convergence is \(C^\infty\), \(dB = 0\); thus \((B, \varphi)\) is a local generalized diffeomorphism. So the local generalized diffeomorphisms are closed.

**Lemma 5.12.** The action of local generalized diffeomorphisms on the deformations, \(\Gamma(\bigwedge^2 L^*)\), of the standard generalized complex structure on \(B_r \subset \mathbb{C}^n\), as in Definition 2.11, is a left SCI-action.

**Proof.** Since this action is defined over precisely the same \(B_r\) as pushforward by local diffeomorphisms, we need only check the estimates (4.7) and (4.8).

Let \(\Phi = (B, \varphi)\) be a local generalized diffeomorphism over a ball \(B_r\). Let \(D\Phi\) be the “derivative” of of \(\Phi\); that is, since \(\Phi\) is a map of trivialized Courant algebroids,
$D\Phi$ is its fibrewise trivialization, a function from $B_r$ to the automorphisms of $T_0B_r \oplus T^*_0B_r \simeq \mathbb{R}^{2n}$. In terms of $B$ and $\varphi$, at a point $x \in B_r$, $D\Phi$ acts as

$$(D\varphi|_x \oplus (D\varphi|_x^T)^{-1}) \circ e^{B|_x},$$

i.e., first by $B$-transform and then by derivative of $\varphi$. If $u \in \Gamma(TB_r \oplus T^*B_r)$ then, similarly to the proof of Lemma 5.9,

$$\Phi_* u = (D\Phi \cdot u) \circ \varphi^{-1}.$$ 

Now we consider a deformation $\varepsilon \in \Gamma(\wedge^2 L^*)$, regarding it as a map $L \rightarrow \bar{L}$. A section of $L_{\Phi,\varepsilon}$ is uniquely represented as $u + (\Phi \cdot \varepsilon)(u)$, for some $u \in \Gamma(L)$. By definition, this is also the image of a section $v + \varepsilon(v) \in \Gamma(L_x)$ under the pushforward $\Phi_*$, for some $v \in \Gamma(L)$. Then

$$u + (\Phi \cdot \varepsilon)(u) = (\Phi_* \circ (Id + \varepsilon))(v) = (D\Phi \cdot (Id + \varepsilon) \cdot v) \circ \varphi^{-1}$$

We decompose the right hand side into $L$ and $\bar{L}$ components, and equate with the corresponding components on the left hand side. First, the $L$ component:

$$u = ((D\Phi \cdot (Id + \varepsilon))^L \cdot v) \circ \varphi^{-1}$$

Then

$$v = (D\Phi \cdot (Id + \varepsilon))^L_{\bar{L}} \cdot (u \circ \varphi).$$

For the $\bar{L}$ component,

$$(\Phi \cdot \varepsilon)(u) = \left( (D\Phi \cdot (Id + \varepsilon))^L_{\bar{L}} \cdot v \right) \circ \varphi^{-1} = \left( (D\Phi \cdot (Id + \varepsilon))^L_{\bar{L}} \cdot (D\Phi \cdot (Id + \varepsilon))^{\bar{L}}_{\bar{L}} \cdot (u \circ \varphi) \right) \circ \varphi^{-1} = \left( (D\Phi \cdot (Id + \varepsilon))^L_{\bar{L}} \cdot (D\Phi \cdot (Id + \varepsilon))^{\bar{L}}_{\bar{L}} \circ \varphi^{-1} \right) \cdot u \tag{5.8}$$

If we drop the $u$ from either side, we have an explicit expression for $\Phi \cdot \varepsilon$. It is constructed from $\varepsilon$, $\Phi$, $D\Phi$ and $Id$ through the operations of sum, matrix multiplication and matrix inverse, pushforward by functions, and restriction and projection (to $L$ and $\bar{L}$). Each of these operations is an SCI-action in the weak sense of Lemma 5.8, and so the result follows.

6. Checking the hypotheses of the abstract normal form theorem

6.1. Preliminary estimates.

**Lemma 6.1.** If $\Theta : V_1 \times V_2 \rightarrow W$ is a bilinear function between normed finite-dimensional vector spaces, and $f : U \rightarrow V_1$ and $g : U \rightarrow V_2$ are smooth on a compact domain $U$, then, applying $\Theta$ to $f$ and $g$ pointwise,

$$\|\Theta(f, g)\|_k \leq \mathcal{C}(\|f\|_k \|g\|_0 + \|f\|_0 \|g\|_k) \leq \mathcal{C}' \|f\|_k \|g\|_k,$$

and of course, $\|\Theta(f, g)\|_k \leq \mathcal{L}(\|f\|_k, \|g\|_k)$.

**Proof.** As remarked in Proposition 4.4, as a consequence of the existence of smoothing operators on spaces of smooth functions, the interpolation inequality holds—for nonnegative integers $p \geq q \geq r$ and any function $f$ as above,

$$\|f\|_q^{p-r} \leq C \|f\|_p^{p-q} \|f\|_q^{q-r}.$$

From this inequality, the result follows by a standard argument (see [11, Cor. II.2.2.3]).
Lemma 6.2. If $\alpha \in \Gamma(\wedge^i L^*)$ and $\beta \in \Gamma(\wedge^j L^*)$, then for $k \geq 0$,

$$
\|\alpha, \beta\|_k \leq C (\|\alpha\|_{k+1}\|\beta\|_1 + \|\alpha\|_1\|\beta\|_{k+1}) \leq C'\|\alpha\|_{k+1}\|\beta\|_{k+1},
$$

and of course, $\|\alpha, \beta\|_k \leq \mathcal{E}(\|\alpha\|_{k+1}, \|\beta\|_{k+1})$.

Proof. If $\alpha$ and $\beta$ are generalized vector fields, there are pointwise-bilinear functions $\Theta$ and $\Lambda$ which express the Courant bracket formula (1.1) as

$$
[\alpha, \beta] = \Theta(\alpha, \beta^{(1)}) - \Lambda(\beta, \alpha^{(1)}).
$$

Then by Lemma 6.1,

$$
\|\alpha, \beta\|_k \leq C' (\|\alpha\|_k\|\beta^{(1)}\|_0 + \|\alpha\|_0\|\beta^{(1)}\|_k
+ \|\alpha^{(1)}\|_{k+1}\|\beta^{(1)}\|_0)
\leq C (\|\alpha\|_{k+1}\|\beta\|_1 + \|\alpha\|_1\|\beta\|_{k+1})
$$

If $\alpha$ and $\beta$ are higher-rank tensors and the bracket is the generalized Schouten bracket, a suitable choice of $\Theta'$ and $\Lambda'$ will give the same result.  \(\square\)

6.2. Verifying estimates (4.10), (4.11), (4.12) and (4.13). Recall that if $\varepsilon = \varepsilon_1 + \varepsilon_2 + \varepsilon_3 \in \Gamma(\wedge^2 L^*)$, with the terms being a bivector, a mixed term and 2-form respectively, then $\zeta(\varepsilon) = \varepsilon_2 + \varepsilon_3$. Then the following is an obvious consequence of our choice of norms.

Lemma 6.3 (Estimate 4.10). For all $\varepsilon \in \Gamma(\wedge^2 L^*)$ and any $k$, $\|\zeta(\varepsilon)\|_k \leq \|\varepsilon\|_k$.

We recall following estimate, taken from [18], which was mentioned in Lemma 3.2:

Lemma 6.4. For all $\varepsilon \in \Gamma(\wedge^2 L^*)$ and any $k$, $\|P\varepsilon\|_k \leq C\|\varepsilon\|_k$.

Lemma 6.5 (Estimate 4.11). For any $\varepsilon \in \Gamma(\wedge^2 L^*)$ and large enough $k$,

$$
\|V(\varepsilon)\|_k \leq C\|\zeta(\varepsilon)\|_{k+1} (1 + \|\varepsilon\|_{k+1}).
$$

Proof. $V(\varepsilon) = P[\varepsilon_1, P\varepsilon_2] - P\varepsilon(\varepsilon)$. But $\|\varepsilon_1\|_k \leq \|\varepsilon\|_k$ and $\|\varepsilon_2\|_k \leq \|\zeta(\varepsilon)\|_k$, so by applying the triangle inequality and then Lemmas 6.4 and 6.2 the result follows. \(\square\)

Lemma 6.6 (Estimate 4.12). For any $v \in \Gamma(L^*)$, any $0 \leq t \leq 1$ and large enough $k$,

$$
\|\Phi_{tv} - Id\|_k \leq \mathcal{E}(\|v\|_k)
$$

Proof. Let $v = X + \xi$, where $X$ is a vector field and $\xi$ is a 1-form, and let $\Phi_{tv} = (B_{tv}, \varphi_{tv})$. From [16] we know that a counterpart of this lemma holds for the local diffeomorphism $\varphi_{tv}$, therefore we are only concerned with $B_{tv}$. By the SCI-action estimate (4.7) for pullbacks of differential forms,

$$(6.1) \quad \|\varphi_{tv}^* d\xi\|_{k-1} \leq \mathcal{E}(\|\xi\|_k, 1 + \|\varphi_{tv} - Id\|_k)$$

The counterpart of this Lemma in [16] tells us that

$$
\|\varphi_{tv} - Id\|_k \leq \mathcal{E}(\|X\|_k).
$$

We plug this into (6.1) and recall that $\|v\|_k = \sup(\|X\|_k, \|\xi\|_k)$; then,

$$
\|\varphi_{tv}^* d\xi\|_{k-1} \leq \mathcal{E}(\|v\|_k).
$$
But
\[\|B_{tv}\|_{k-1} = \left\| \int_0^t (\varphi_{tX}^* \xi) \, d\tau \right\|_{k-1}\]
\[\leq \int_0^t \|\varphi_{tX}^* \xi\|_{k-1} \, d\tau\]
\[\leq \int_0^t \mathcal{L}(\|v\|_k) \, d\tau\]
and the result follows. \(\square\)

**Lemma 6.7** (Estimate 4.13). *There is some \(s\) such that, for any \(v, w \in \Gamma(L^*)\), any integrable deformation \(\varepsilon \in \Gamma(\wedge^s L^*)\), and large enough \(k\),
\[\|\Phi_v \cdot \varepsilon - \Phi_w \cdot \varepsilon\|_k \leq \mathcal{L}(\|v - w\|_{k+1}, 1 + \|v\|_{k+2} + \|w\|_{k+2} + \|\varepsilon\|_{k+1})\]
\[+ \mathcal{L}((\|v\|_{k+3} + \|w\|_{k+3})^2, 1 + \|\varepsilon\|_{k+2})\]

(6.2)

**Proof.** The integral form of Proposition 2.17 tells us that
\[\Phi_v \cdot \varepsilon - \Phi_w \cdot \varepsilon = \int_0^1 (\partial v + [v, \varphi_{tv} \cdot \varepsilon]) \, dt - \int_0^1 (\partial w + [w, \varphi_{tw} \cdot \varepsilon]) \, dt\]
\[= \partial(v - w) + \int_0^1 [v - w, \varphi_{tv} \cdot \varepsilon] \, dt + \int_0^1 [w, \varphi_{tw} \cdot \varepsilon - \varphi_{tv} \cdot \varepsilon] \, dt\]

Integrating again, this time within the second Courant bracket, we get
\[\partial(v - w) + \int_0^1 [v - w, \varphi_{tv} \cdot \varepsilon] \, dt\]
\[+ \int_0^1 \int_0^t [w, \partial(v - w) + [v, \varphi_{tv} \cdot \varepsilon] - [w, \varphi_{tw} \cdot \varepsilon]] \, d\tau \, dt\]

To estimate \(\|\Phi_v \cdot \varepsilon - \Phi_w \cdot \varepsilon\|_k\), we apply the triangle inequality to (6.3), and consider the three terms in turn. Clearly, \(\|\partial(v - w)\|_k\) is bounded by the first term in (6.2).

An aside: using the action estimate (4.9) and then Lemma 6.6, we see that
\[\|\varphi_{tv} \cdot \varepsilon\|_k \leq \mathcal{L}(\|\varepsilon\|_k + \|v\|_{k+1}).\]

Turning now to the second term of (6.3), we carry the norm inside the integral then, using the bracket estimate (Lemma 6.2) and the above remark, we see that this term is bounded by the first term in (6.2). Similarly, the third term in (6.3) will be bounded by terms which have a factor of \(\|v - w\|, \|v\| \cdot \|v\|\) or \(\|w\|^2\). Counting the total number of derivatives lost on each factor, the result follows. \(\square\)

6.3. **Lemmas for estimate** (4.14). The following lemma says that in our case the operator \(\partial + [\varepsilon, \cdot]\) is a good approximation of the deformed Lie algebroid differential \(\partial + [\varepsilon, \cdot]\).

**Lemma 6.8.** For any \(\varepsilon \in \Gamma(\wedge^2 L^*)\) and large enough \(k\),
\[\|((\partial V(\varepsilon) + [\varepsilon, V(\varepsilon)]) - (\partial V(\varepsilon) + [\varepsilon_1, V(\varepsilon)])\|_k \leq C\|\zeta(\varepsilon)\|_{k+2}^2 (1 + \|\varepsilon\|_{k+2})\]
Proof:
\[
\left\| (\bar{\partial}V(\varepsilon) + [\varepsilon, V(\varepsilon)]) - (\bar{\partial}V(\varepsilon) + [\varepsilon_1, V(\varepsilon)]) \right\|_k = \left\| [\zeta(\varepsilon), V(\varepsilon)] \right\|_k \\
\leq C \|\zeta(\varepsilon)\|_{k+1} \|V(\varepsilon)\|_{k+1} \\
\leq C \|\zeta(\varepsilon)\|^2_{k+2} (1 + \|\varepsilon\|_{k+1}),
\]
(\text{using Lemma 6.5 for the last step}).

The following lemma should be viewed as an approximate version of Proposition 3.1, telling us that the infinitesimal action of \(V\) on \(\varepsilon\) almost eliminates the non-bivector component.

Lemma 6.9. For an integrable deformation \(\varepsilon \in \Gamma(\wedge^2 L^*)\) and large enough \(k\),
\[
\| \zeta \left( \bar{\partial}V(\varepsilon) + [\varepsilon_1, V(\varepsilon)] + \varepsilon \right) \|_k \leq C \|\zeta(\varepsilon)\|^2_{k+2} (1 + \|\varepsilon\|_{k+2})
\]

Proof.
\[
\bar{\partial}V(\varepsilon) + [\varepsilon_1, V(\varepsilon)] = \bar{\partial}P[\varepsilon_1, P\varepsilon_3] - \bar{\partial}P\varepsilon_2 - \bar{\partial}P\varepsilon_3 + [\varepsilon_1, P[\varepsilon_1, P\varepsilon_3]] - [\varepsilon_1, P\varepsilon_2] - [\varepsilon_1, P\varepsilon_3]
\]
The terms \([\varepsilon_1, P\varepsilon_2]\) and \([\varepsilon_1, P[\varepsilon_1, P\varepsilon_3]]\) lie in \(\wedge^2 T_{1,0}\), so
\[
\zeta \left( \bar{\partial}V(\varepsilon) + [\varepsilon_1, V(\varepsilon)] \right) = \bar{\partial}P[\varepsilon_1, P\varepsilon_3] - \bar{\partial}P\varepsilon_2 - \bar{\partial}P\varepsilon_3 - [\varepsilon_1, P\varepsilon_3].
\]
We apply the identity \(\bar{\partial}P = 1 - P\bar{\partial}\) (3.2) to the first three terms on the right hand side, giving us
\[
[\varepsilon_1, P\varepsilon_3] - P\bar{\partial}[\varepsilon_1, P\varepsilon_3] - \varepsilon_2 + P\bar{\partial}\varepsilon_2 - \varepsilon_3 + P\bar{\partial}\varepsilon_3 - [\varepsilon_1, P\varepsilon_3]
\]
(6.4) \(= -P\bar{\partial}[\varepsilon_1, P\varepsilon_3] + P\bar{\partial}\varepsilon_2 + P\bar{\partial}\varepsilon_3 - \zeta(\varepsilon)
\]
We now use the fact that \(\varepsilon\) satisfies the Maurer-Cartan equations, (2.6) through (2.9). By (2.9), \(P\bar{\partial}\varepsilon_3\) vanishes. By (2.8),
\[
P\bar{\partial}\varepsilon_2 = -P \left( \frac{1}{2}[\varepsilon_2,\varepsilon_2] + [\varepsilon_1,\varepsilon_3] \right).
\]
By equation 3.3,
\[
-P\bar{\partial}[\varepsilon_1, P\varepsilon_3] = P[\varepsilon_1, \bar{\partial}P\varepsilon_3] - P[\bar{\partial}\varepsilon_1, P\varepsilon_3]
\]
(6.6) \(= P[\varepsilon_1, \varepsilon_3] - P[\bar{\partial}\varepsilon_1, P\varepsilon_3]
\]
\(P[\varepsilon_1, \varepsilon_3]\) cancels between (6.5) and (6.6). Thus (6.4) becomes
\[
-\frac{1}{2} P[\varepsilon_2,\varepsilon_2] - P[\bar{\partial}\varepsilon_1, P\varepsilon_3] - \zeta(\varepsilon)
\]
Applying (2.7) to \(\bar{\partial}\varepsilon_1\), this is
\[
-\frac{1}{2} P[\varepsilon_2,\varepsilon_2] + P[[\varepsilon_1,\varepsilon_2],\varepsilon_3] - \zeta(\varepsilon)
\]
Through applications of Lemmas 6.4 and 6.2, we find that the first two terms have \(k\)-norm bounded by
\[
C \left( \|\varepsilon_2\|^2_{k+1} + \|\varepsilon_1\|_{k+2} \|\varepsilon_2\|_{k+2} \|\varepsilon_3\|_{k+1} \right) \leq C \|\zeta(\varepsilon)\|^2_{k+2} (1 + \|\varepsilon\|_{k+2})
\]
The result follows. □

The following lemma is a version of Taylor’s theorem.
Lemma 6.10. There is some \( s \) such that for any integrable deformation \( \varepsilon \in \Gamma(\wedge^2 L^*) \), any \( v \in \Gamma(L^*) \), and large enough \( k \),
\[
\| (\Phi_v \cdot \varepsilon - \varepsilon) - (\partial v + [\varepsilon, v]) \|_k \leq \mathcal{L}(1 + \| \varepsilon \|_{k+s}, \| v \|_{k+s}).
\]

Proof. Applying the integral form of Proposition 2.17, we see that
\[
\| (\Phi_v \cdot \varepsilon - \varepsilon) - (\partial v + [\varepsilon, v]) \|_k = \left\| \int_0^1 (\partial v + [\Phi_{tv} \cdot \varepsilon, v]) dt - (\partial v + [\varepsilon, v]) \right\|_k
\]
\[
= \left\| \int_1^0 [\Phi_{tv} \cdot \varepsilon - \varepsilon, v] dt \right\|_k
\]
\[
\leq \int_0^1 \mathcal{L}(\| v \|_{k+1}, \| \Phi_{tv} \cdot \varepsilon - \varepsilon \|_{k+1}) dt
\]

Where in the last line we have carried the norm inside the integral and applied Lemma (6.2). Applying the second axiom of SCI-actions (4.8) and then Lemma 6.6, for some \( s \) and \( s' \),
\[
\| \Phi_{tv} \cdot \varepsilon - \varepsilon \|_{k+1} \leq \mathcal{L}(1 + \| \varepsilon \|_{k+s'}, \| \Phi_{tv} - Id \|_{k+s'})
\]
\[
\leq \mathcal{L}(1 + \| \varepsilon \|_{k+s}, \| v \|_{k+s})
\]

Integrating the above estimate, the result follows. \( \square \)

Lemma 6.11 (Estimate 4.14). There is some \( s \) such that, for any integrable deformation \( \varepsilon \in \Gamma(\wedge^2 L^*) \) and large enough \( k \),
\[
\| \zeta(\Phi_{V(\varepsilon)} \cdot \varepsilon) \|_k \leq \| \zeta(\varepsilon) \|_k^{1+s} \text{Poly}(\| \varepsilon \|_{k+s}, \| \Phi_{V(\varepsilon)} - Id \|_{k+s}, \| \zeta(\varepsilon) \|_{k+s}, \| \varepsilon \|_k),
\]
where in this case the polynomial degree in \( \| \varepsilon \|_{k+s} \) does not depend on \( k \).

Proof. This is just an application of the triangle inequality using the estimates in this section. We will show that, in the following series of approximations, terms on either side of \( a \sim \) are close in the sense required:
\[
\zeta(\Phi_{V(\varepsilon)} \cdot \varepsilon - \varepsilon) \sim \zeta(\partial V(\varepsilon) + [\varepsilon, V(\varepsilon)]) \sim \zeta(\partial V(\varepsilon) + [\varepsilon, V(\varepsilon)]) \sim -\zeta(\varepsilon)
\]
If so, then \( \zeta(\Phi_{V(\varepsilon)} \cdot \varepsilon) \sim 0 \) as required.

Applying the estimate for \( V(\varepsilon) \) (Lemma 6.5) to Lemma 6.10, we see that
\[
\| (\Phi_{V(\varepsilon)} \cdot \varepsilon - \varepsilon) - (\partial V(\varepsilon) + [\varepsilon, V(\varepsilon)]) \|_k \leq \mathcal{L}(1 + \| \varepsilon \|_{k+s}, \| \zeta(\varepsilon) \|_{k+s+1}^{2} (1 + \| \varepsilon \|_{k+s')^{2} + 1)).
\]
Applying \( \zeta \) to the left hand side, this is the first approximation above. (We remark that for large \( k \), \( (k+s)/2 \) \( 1 \leq k \), so we have a strictly limited degree in \( \| \varepsilon \| \), \( l > k \).) The remaining approximations are Lemma 6.8 (after applying \( \zeta \) to its left hand side) and Lemma 6.9 respectively. \( \square \)

As remarked in Section 4.3, we should now consider the Main Lemma proved.

7. Main Lemma implies Main Theorem

It is certainly the case that, near a complex point, a generalized complex structure is a deformation of a complex structure. However, this deformation may not be small in the sense we need. Therefore we use two means to control its size.

In this section, by \( \delta_l : \mathbb{C}^n \rightarrow \mathbb{C}^n \) we will mean the dilation, \( x \mapsto tx \). If \( \varepsilon \) is a tensor on \( \mathbb{C}^n \), then by \( \delta_l \varepsilon \) we mean the pushforward of \( \varepsilon \) under the dilation map \( x \mapsto tx \). The complex structure on \( \mathbb{C}^n \) is invariant under \( \delta_l \); therefore if
ε ∈ Γ(Λ²L*) is a deformation of the complex structure, then δₜε = (0, δₜ) · ε as in Definition 2.11.

Suppose that ε ∈ Γ(Λ²L*), where L* = T₁₀ ⊕ T₁₁, and that ε is decomposed into ε₁ + ε₂ + ε₃, where ε₁ is a bivector, ε₃ is a 2-form and ε₂ is of mixed type, as in Section 2.2. We wish to see how δₜ acts on these terms.

**Proposition 7.1.** Suppose that t > 0. For any x ∈ Cⁿ and any k we have the following pointwise norm comparisons for derivatives of ε, before and after the dilation. Let k ≥ 0. Then

\[ \| (δₜε₁)_(k)(tx) \|₀ ≤ t^{2-k} \| ε₁_(k)(x) \|₀ \]
\[ \| (δₜε₂)_(k)(tx) \|₀ ≤ t^{-k} \| ε₂_(k)(x) \|₀ \]
\[ \text{and} \quad \| (δₜε₃)_(k)(tx) \|₀ ≤ t^{-2-k} \| ε₃_(k)(x) \|₀. \]

**Proof.** Under a dilation, vectors scale with t and covectors scale inversely with t.

Then

(7.1) \( (δₜε₁)(tx) = t²ε₁(x), \quad (δₜε₂)(tx) = ε₂(x) \) and \( (δₜε₃)(tx) = t^{-2}ε₃(x). \)

If \( x_i \) is a coordinate and \( f \) a tensor, then

\[ \frac{∂}{∂x_i} (δₜf)(tx) = δₜ \left( \frac{∂}{∂x_i} f \right)(tx) = t^{-1} δₜ \left( \frac{∂}{∂x_i} f \right)(tx) \]

This tells us that

\[ \| (δₜf)_(k+1)(tx) \|₀ ≤ t^{-1} \| δₜ( f_(k) ) (tx) \|₀ \]

By induction on this inequality and then applying the formulas in (7.1), the result follows. □

We now define the \( λ \)-transform, which is not a Courant isomorphism, but which does take generalized complex structures to generalized complex structures.

**Definition 7.2.** If t > 0, let \( λ_t : T ⊕ T^* \rightarrow T ⊕ T^* \) so that \( λ_t(X, ξ) = (tX, ξ) \). Then \( λ_t \) also acts on generalized complex structures by mapping their eigenbundles (or by conjugating \( J \)).

\( λ_t \) commutes with diffeomorphisms, but it does not quite commute with Courant isomorphisms.

**Notation 7.3.** If \( Φ = (B, ϕ) \) is a Courant isomorphism, then let \( λ_t · Φ = (t^{-1}B, ϕ) \).

**Proposition 7.4.** If \( Φ \) is a Courant isomorphism then

\[ Φ ∘ λ_t = λ_t ∘ (λ_t · Φ). \]

Again we consider a deformation \( ε = ε₁ + ε₂ + ε₃ \) of the complex structure on \( Cⁿ \). \( λ_t(L_ε) \) will be another generalized complex structure.

**Proposition 7.5.** \( λ_t(L_ε) = L_{λ_tε} \), where

\[ λ_tε = tε₁ + ε₂ + t^{-1}ε₃. \]

**Remark 7.6.** We can check that this transformation respects the Maurer-Cartan equations, (2.6) through (2.9), which tells us that if \( L_ε \) was generalized complex then so is \( λ_t(L_ε) \).

We can now prove that the Main Theorem follows from the Main Lemma. Recall:
Main Lemma. Let $J$ be a generalized complex structure on the closed unit ball $B_1$ about the origin in $\mathbb{C}^n$. Suppose that $J$ is a small enough deformation of the complex structure on $B_1$, and suppose that $J$ is of complex type at the origin. Then, in a neighbourhood of the origin, $J$ is equivalent to a deformation of the complex structure by a holomorphic Poisson structure on $\mathbb{C}^n$.

Main Theorem. Let $J$ be a generalized complex structure on a manifold $M$ which is of complex type at point $p$. Then, in a neighbourhood of $p$, $J$ is equivalent to a generalized complex structure induced by a holomorphic Poisson structure, for some complex structure near $p$.

Proof of Main Theorem from Main Lemma. Suppose that $J$ is a generalized complex structure on $M$, with $p$ a point of complex type. We may assume without loss of generality that $p = 0$ in the closed unit ball $B_1 \subset \mathbb{C}^n$, where the complex structure on $T_0 \mathbb{C}^n$ induced by $J$ agrees with the standard one. By application of an appropriate $B$-transform, we may assume that, at 0, $J$ agrees with the standard generalized complex structure, $J_{\mathbb{C}^n}$, for $\mathbb{C}^n$. Then, near 0, $J$ is a deformation of $J_{\mathbb{C}^n}$ by $\varepsilon \in \Gamma(\Lambda^2 \mathbb{L}^*)$, and $\varepsilon$ vanishes at 0.

For $t > 0$, let

$$R_t \varepsilon = \delta_{t^{-1}} \lambda_{t^2} \varepsilon = \lambda_{t^2} \delta_{t^{-1}} \varepsilon.$$  

Since $\varepsilon$ (and hence $R_t \varepsilon$) vanishes at 0 to at least first order, there is some $C > 0$ such that, for all $0 < t \leq 1$,

$$\|(R_t \varepsilon)(x)\|_0 \leq C t \|(R_t \varepsilon)(t^{-1}x)\|_0.$$  

(7.2)

For derivatives $k > 0$, we apply Proposition 7.1 to the components $\varepsilon_1$, $\varepsilon_2$ and $\varepsilon_3$, and

$$\|(R_t \varepsilon_1)(t^{-1}x)\|_0 \leq t^{-2+k} \|(\lambda_{t^2} \varepsilon_1)(k)(x)\|_k,$$

$$\|(R_t \varepsilon_2)(t^{-1}x)\|_0 \leq t^k \|(\lambda_{t^2} \varepsilon_2)(k)(x)\|_k$$

and

$$\|(R_t \varepsilon_3)(t^{-1}x)\|_0 \leq t^{2+k} \|(\lambda_{t^2} \varepsilon_3)(k)(x)\|_k.$$  

Using Proposition 7.5, we apply $\lambda_{t^2}$, so that

$$\|(R_t \varepsilon_1)(k)(t^{-1}x)\|_0 \leq t^k \|\varepsilon_1^{(k)}(x)\|_k,$$

$$\|(R_t \varepsilon_2)(k)(t^{-1}x)\|_0 \leq t^k \|\varepsilon_2^{(k)}(x)\|_k$$

and

$$\|(R_t \varepsilon_3)(k)(t^{-1}x)\|_0 \leq t^k \|\varepsilon_3^{(k)}(x)\|_k.$$  

Thus, if $k > 0$ or (because of (7.2), if $k = 0$ also), we have

$$\|(R_t \varepsilon)(k)(x)\|_0 \leq C t \|\varepsilon^{(k)}(x)\|_0.$$  

So,

$$\|(R_t \varepsilon)(x)\|_k \leq C t \|\varepsilon(x)\|_k.$$  

Taking the sup-norm always over the fixed set $B_1$, we have that $\|R_t \varepsilon\|_k \leq C t \|\varepsilon\|_k$. Thus $\|R_t \varepsilon\|_k$ is as small as we like for some $t$, and satisfies the hypotheses of the Main Lemma; so there exists a local Courant isomorphism $\Phi$ such that $\Phi_t \cdot R_t \varepsilon = \beta$, where $\beta$ is a holomorphic Poisson bivector. Then

$$\beta = \Phi_t \cdot (\lambda_{t^2} \delta_{t^{-1}} \varepsilon)$$

$$= \lambda_{t^2} ((\lambda_{t^2} \cdot \Phi_t) \cdot \delta_{t^{-1}} \varepsilon)$$
But the action of $\lambda t^2$ on a bivector is just scaling by $t^2$, so

$$(\lambda t^2 \cdot \Phi t) \cdot \delta_{t^{-1}} \varepsilon = t^{-2} \beta.$$ 

Thus, starting from a suitably small neighbourhood of 0, by applying first the
dilation $\delta_{t^{-1}}$ and then the Courant isomorphism $\lambda t^2 \cdot \Phi t$, we see that $\varepsilon$ is locally
equivalent to the holomorphic Poisson structure $t^{-2} \beta$. □
