Comprehensive examination of radiative electromagnetic flowing of nanofluids with viscous dissipation effect over a vertical accelerated plate

Shankar Goud Bejawada¹, Yanala Dharmendar Reddy², Wasim Jamshed³, Usman⁴, Siti Suzilliana Putri Mohamed Isa⁵, Sayed M. El Din⁶, Kamel Guedri⁷ & M. Israr Ur Rehman⁸

This research aims to establish the MHD radiating convective nanofluid flow properties with the viscous dissipation across an exponentially accelerating vertical plate. As the plate accelerates, its temperature progressively increases. There are two separate types of water-based nanofluids that include copper (Cu) and titanium dioxide (TiO₂) nanoparticles, respectively. The most crucial aspect of this investigation is finding a closed-form solution to a nonlinear coupled partial differential equations scheme. Galerkin finite element method (G-FEM) is used to figure out the initial managing equations. Utilizing graphs, the effect of the flow phenomenon's contributing variables as well as the influence of other factors is determined and depicted. In the part dedicated to the findings and discussion, the properties of these emergent parameters are described in more depth. Nonetheless, the thermal radiation and heat sink factors increase the thermal profile. In addition, the greater density of the copper nanoparticles cause the nanoparticle volume fraction to lessen the velocity delineation.

List of symbols

| Symbol | Description |
|--------|-------------|
| u*     | The factor of nanofluid velocity in the path of x-axis (ms⁻¹). |
| g      | Acceleration due to gravity (ms⁻²). |
| ρf     | Nanoparticles density (kg m⁻³). |
| ρnf    | Nanofluid density (kg m⁻³). |
| T*     | Temperature of the nanofluid (K). |
| μnf    | Viscosity of the nanofluid (kg m⁻¹ s⁻¹). |
| σ      | Electrical conductivity. |
| βnf    | Volumetric coefficient of thermal expansion of the nanofluid. |
| knf    | Nanofluid thermal conductivity (W m⁻¹ K⁻¹). |
| qr     | Radiation flux (W m⁻²). |
| K      | The permeability of medium. |
| (cp)nf | Specific heat at constant pressure of the nanofluid. |
| ν      | The coefficient of kinematics viscosity. |
| M      | Magnetic parameter. |
| Pr     | Prandtl number. |
| Gr     | Grashof number. |

Heat transfer is the heat propagation between two separate structures or surroundings. Heat is propagated through conducting material (conduction), fluids (convection), and electromagnetic waves (radiation). The primary condition of heat transfer is the temperature of the structures and surroundings must be different (there must be a temperature gradient between these two systems or regions). Some of the applications of heat transfer in the industry are heat exchangers, pulsed spray cooling, magnetic cooling, thermal reservoir, etc.

Nanofluid is a colloidal solution that contains one type of particles in nanometer-sized in a based liquid, which is known as nanoparticles. The selected nanoparticles are oxides, metals, carbides, or carbon nanotubes, while the base fluids are water, oil, and ethylene glycol. The properties of the nanofluid are more significant than a conventional fluid which enhance the thermal conductivity, specific heat, and viscosity of the liquid. The potential usage of nanofluid in industrial cooling for tremendous energy savings and resulting in emissions reductions nanofluid coolant in automotive applications for smaller size and the more excellent location of the radiators, computer cooling system, etc. Tiwari and Das model treated the fluid, velocity, and temperature as constant, because this model is single phase. The nanoparticles and base fluid elements in this model are assumed to be in thermal equilibrium, and the in-contact condition between these two elements is non-slip. In addition, the influence of nanoparticles volume fraction is also being deliberated. The implemented Tiwari-Das model has been reported recently, with the various two-dimensional model such as when the nanofluid is flowing over a stretching sheet, porous media, and cylinder etc.

Titanium dioxide (TiO\textsubscript{2}) is one type of nanoparticle with diameters less than 100 nm. Because of the bright whiteness owned by TiO\textsubscript{2}, and it is being considered safe, it is used in products such as food additives. These two nanoparticles (Cu and TiO\textsubscript{2}) can be submerged simultaneously in the same base fluid for hybrid nanofluid preparation, where the hybrid nanofluid flow and thermal properties are affected by suction and viscous dissipation effects, thermal radiation, or porous medium. Khan et al. investigated the Cu-TiO\textsubscript{2} hybrid nanofluid, where its flow is induced by non-Fourier heat flux.

The boundary layer flow beyond a vertical plate or surface has been observed in many industrial processes, namely nuclear reactors, filtration procedures, drying porous materials in textile manufacturing, etc. The nanofluid flow beyond a semi-infinite plate due to the thermal conductivity is reported by Loganathan and Sangeetha. The inclined magnetic field is included in the nanofluid flow model, which is bounded by convection conditions. Haider et al. analyzed the unsteady state of hybrid nanofluids flow over an oscillating infinite vertical plate, with the effect of Newtonian heating.

Recently, the magnetic field in fluid convection (known as magnetohydrodynamics MHD) have enormous applications in medical science like thermo-chemotherapy. On the other hand, thermal radiation acts as a heat transfer controller in polymer processing, and solar power operation. Moreover, the MHD radiating nanofluid flow over a horizontal plate or surface has been published for flat sheet, cylinder etc.

The Galerkin finite element technique provides numerical solutions. Firstly, the multiplication of the weight function is performed to obtain the integral in the domain. Subsequently, together with the trail function, the step function is also selected with the order of interpolation. Then, each element was numerically calculated by integration to get the equations system. Finally, this system is solved to obtain the final solution. The hybrid nanofluid contains nanoparticles of copper and magnetite (Fe\textsubscript{3}O\textsubscript{4}), which flow over an infinite porous surface and is studied by Alkathiri et al. for thermal properties with the presence of entropy generation. The thermal performance of MHD radiating Williamson nanofluid flow bounded by infinite convective surface, with aluminum alloys (AA7072) and titanium alloy (Ti6Al4V) are studied by Hussain et al. They investigated the controlled factors of their mathematical model, known as viscous dissipation, Brownian, Joule heating, and thermophoresis diffusion. Pasha et al. studied the thermal radiation acting on the Powell-Eyring Cu-TiO\textsubscript{2} hybrid nanofluid flow over an infinite slippery surface. The magnetohydrodynamics Ag-MgO hybrid nanofluid flows inside a porous triangular cavity were reported by Redouane et al. The flow and thermal features of Sutterby Cu-GO hybrid nanofluid over a slippery porous surface are investigated by Bouslimi et al., affected by viscous dissipation, thermal radiation, and solid-shaped nanoparticles. The mixed convection Maxwell MoS-Ag hybrid nanofluid over an infinite porous stretching sheet and the heat is generated or absorbed is considered by Algehyne et al. The Cattaneo–Christov heat flux model in the hybrid nanofluid flow over two distinct shapes and two parallel rotating disks have analyzed the following models of hybrid nanofluid flow: between two parallel Darcy porous plates, over a extending or compressing wedge with the implementation of Falkner–Skan Problem, over an irregular variably thick convex/concave-shaped porous medium sheet, and past a permeable moving surface with with assisting and opposing flow. Priya et al. have inspected the radiating micropolar hybrid nanofluid flow past a vertical porous plate. Rawat and Kumar studied the copper water nanofluid with the utilization of Cattaneo–Christov heat flux model. The double-diffusion copper–water nanofluid flow model with the employment of Cattaneo–Christov scheme and Stefan blowing has been discussed by Negi et al. The nanofluid flow over a vertical Riga plate is studied by Sawan et al.

In light of the previously mentioned information, this paper is desired to examine nanofluid optically thick radiative MHD free convection flow across the exponentially accelerating porous plate. In addition, free convection become the main factor since it is caused by the thermal buoyancy outcome, and the innovation of this paper is the incorporation of both heat sinks and thermal radiation in the energy equation. Many researchers...
have focused on the boundary layer flows of nanofluids induced by vertical plates. Their immense importance in engineering and industrial applications has been the driving force behind this development. These applications are especially prevalent in extrusion operations, the production of paper and glass fibre, the fabrication of electronic chips, the application of paint, the preparation of food, and the transfer of biological fluids. It is worthwhile to employ the Galerkin finite element technique, despite the fact that the differential equations are incomplete because of the instability. Various flow parameters’ behaviors are obtained and explained graphically.

**Formulation of the problem**

This work takes into consideration:

1. optically thick water-based electrically conducting radiative MHD nanofluid flow along an accelerated exponentially ramping wall temperature integrated with permeable medium, positioned vertically upward.
2. It is well known that the flow occurs along the \(x^*\) axis and that the \(y^*\) axis represents its transverse direction.
3. For \(t^* \leq 0\), it is assumed that there is no motion in the fluid, i.e., no flow happens.
4. The plate velocity is supposed to be increased exponentially, i.e., \(U_0 e^{a t^*}\) along the flow direction, and the plate temperature of the plate is supposed to be unchanged, i.e., \(T^*_w\).
5. A magnetic field (strength \(B_0\)) that intersects with the vertical plate, is provided to the flow in a normal direction (Fig. 1).

The governing equations for nanofluids, articulated in vector version, are as follows:

\[
\nabla \cdot \mathbf{U} = 0
\]

\[
\rho_{nf} \frac{\partial \mathbf{U}}{\partial t} = -\nabla p + \mu_{nf} \nabla^2 \mathbf{U} + \mathbf{J} \times \mathbf{B} + \mathbf{F},
\]

\[
(\rho c_p)_{nf} \frac{\partial T^*}{\partial t^*} = -\nabla \cdot \mathbf{q}^r
\]

where \(U = (u, v, w), q = -\kappa_{nf} \nabla T\) the heat flux, and \(J = \sigma_{nf} (E + U \times B)\) the current density.

Consideration is also given to the Rosseland-based radiative heat flow \(q_\text{r}\). Considered here to be an isolated pressure gradient. Water containing nanoparticles of metals such as copper (Cu) and Titanium oxide TiO\(_2\) is regarded as a nanofluid. The Eqs. (4–6) are inspired by Das and Jana\(^{43}\) and they are presented as below:

\[
\rho_{nf} \frac{\partial u^*}{\partial t^*} = \mu_{nf} \frac{\partial^2 u^*}{\partial y^*} - \sigma_{nf} B_0^2 u^* - \frac{\mu_{nf}}{K} u^* + g(\rho \beta_T)_{nf} (T^* - T_{\infty}^*)
\]

\[
(\rho c_p)_{nf} \frac{\partial T^*}{\partial t^*} = k_f \frac{\partial^2 T^*}{\partial y^*} - \frac{\partial q_\text{r}^*}{\partial y^*} + Q_0 (T^* - T_{\infty}^*) + \mu_{nf} \left( \frac{\partial u^*}{\partial y^*} \right)^2
\]
Applying the Rosseland approximation at this point
\[ q_r = -\frac{4\sigma^*}{k^*} \frac{\partial T^*}{\partial y^*} \]  

(7)

When \( T^* \) is simplified further using Taylor’s series expansion regarding \( T^*_N \) and when just linear terms are considered, we get
\[ T^* \approx 4T_N^3 - 3T_N^4 \]  

(8)

Using the preceding expression, Eq. (6) has the following form:
\[ (\rho c_p)_nf \frac{\partial T^*}{\partial t^*} = k_{nf} \frac{\partial^2 T^*}{\partial y^*^2} + \frac{16T_N^2\sigma^*}{k^*} \frac{\partial^2 T^*}{\partial y^*^2} + Q_0(T^* - T_N^*) + \mu_{nf} \left( \frac{\partial u^*}{\partial y^*} \right)^2 \]  

(9)

The following is a summary of the nanofluid’s physical characteristics, based on Das and Jana’s43 research:
\[ \rho_{nf} = (1 - \phi)\rho_f + \phi\rho_\infty, \mu_{nf} = \frac{\mu_f}{(1 - \phi)^2}, \]
\[ (\rho c_p)_{nf} = \frac{(1 - \phi)(\rho c_p)_f + \phi(\rho c_p)_s}{(\rho c_p)}, \]
\[ (\rho\beta_t)_{nf} = \frac{(1 - \phi)(\rho\beta_t)_f + \phi(\rho\beta_t)_s}{(\rho\beta_t)}, \]
\[ \sigma_{nf} = \sigma_f \left[ 1 + \frac{3(\frac{\sigma_f}{\sigma_t} - 1)\phi}{(\frac{\sigma_f}{\sigma_t} + 2) - \frac{3(\sigma_f/\sigma_t - 1)\phi}{\sigma_f} + 2k_f - 2\phi(k_f - k_s) \right] \]
\[ k_{nf} = k_f \left( \frac{k_s + 2k_f - 2\phi(k_f - k_s)}{k_s + 2k_f + \phi(k_f - k_s)} \right) \]

With the aid of the following dimensionless variables
\[ y = \frac{y^*}{U_0\nu_0}, t = \frac{t^*}{\nu_0}, u = \frac{u^*}{U_0}, T = \frac{T^* - T_N^*}{T_N^* - T_N^*} \]

And substituting in Eqs. (4), (6), and (9), we get:
\[ \frac{\partial u^*}{\partial t} = \frac{\partial^2 u^*}{\partial y^*^2} + r_2Gr\theta - \left( r_3M + \frac{1}{K_P} \right) u, \]  

(10)

\[ \frac{\partial \theta^*}{\partial t} = \frac{\partial^2 \theta^*}{\partial y^*^2} + r_1 + r_2\theta^* + r_3 Ec \left( \frac{\partial u^*}{\partial y^*} \right)^2 \]  

(11)

Surface conditions are
\[ t \leq 0 : u = 0, \theta = 0, \quad \forall y \geq 0, \]
\[ t > 0 : \{ \begin{array}{l} u = c_{at}, \theta = 1, \quad \forall y \geq 0 \\text{at} \ y = 0 \\ u \to 0, \theta \to 0 \quad \text{as} \ y \to \infty \end{array} \]  

(12)

where \( M = \frac{\gamma R_e^2 U_0}{U_0\nu_0} \) is the magnetic field, \( Gr = \frac{\gamma \nu_0(T_N - T_N^*)}{U_0^3} \) is the Modified Grashof number, \( Pr = \frac{(\rho c_p)_f}{\nu_0} \) refers to the Prandtl number, \( R = \frac{4\sigma^* T_N^3}{k^*} \) indicates the radiation parameter, \( Q = \frac{Q_0}{U_0^2(\mu_f)} \) is the heat source/sink parameter and \( K_P = \frac{K_P}{U_0^2} \) is the porosity factor.
During this step, the whole problem area is broken up into smaller parts called "finite elements." The component \( r_1 \) and the basis functions, which are in this stage, the linear solution to the component, are taken into consideration.

\[
r_1 = \frac{1}{(1 - \phi)^2} \left( \frac{\partial^2 u}{\partial y^2} + \phi \frac{\partial u}{\partial y} \right),
\]

\[
r_2 = (1 - \phi) + \phi \left( \frac{\partial \phi}{\partial y} \right),
\]

\[
r_3 = \left[ 1 + \frac{3(\frac{\phi}{\phi_0} - 1)}{(\phi_0 + 2) - (\frac{\phi}{\phi_0} - 1)} \right],
\]

\[
r_4 = \frac{1}{(1 - \phi) + \phi} \left( \frac{\partial^2 u}{\partial y^2} + \frac{\partial u}{\partial y} \right),
\]

\[
r_5 = \frac{Q}{(1 - \phi) + \phi},
\]

\[
r_e = \frac{1}{(1 - \phi)^2 x_e}
\]

The quantifiable thermal aspects of liquid and nanoparticles are presented in Table 1.

### Problem solution: Galerkin finite element method

The Galerkin weighted residual numerical approach is implemented in conjunction with a robust FEM solution to deal with the dimensionless complex partial differential Eqs. (10–11) and (13). Following are the five stages that make up this full procedure.

Some of these steps involve.

**Step-1: discretization.** During this step, the whole problem area is broken up into smaller parts called "finite elements." The component \( e \) is expanded by using the Galerkin finite element technique for Eq. (10), is

\[
\int_{y_j}^{y_k} \left\{ \left( N^{(e)} \right) \left[ r_1 \frac{\partial^2 u^{(e)}}{\partial y^2} + \frac{\partial u^{(e)}}{\partial y} + 2Gr \theta - (r_3M + \frac{1}{K_p}) u^{(e)} + P \right] \right\} dy = 0
\]

Using the by-parts method to put the first part together

\[
N^{(e)} \left\{ \frac{\partial u^{(e)}}{\partial y} \right\} \int_{y_j}^{y_k} \left\{ N^{(e)} \left[ r_1 \frac{\partial N^{(e)}}{\partial y} + \frac{\partial u^{(e)}}{\partial y} - 2Gr \theta + \left( r_3M + \frac{1}{K_p} \right) u^{(e)} - P \right] \right\} dy = 0
\]

Leaving out the first part of Eq. (14), the following can be found:

\[
\int_{y_j}^{y_k} \left\{ N^{(e)} \left[ r_1 \frac{\partial N^{(e)}}{\partial y} + \frac{\partial u^{(e)}}{\partial y} - 2Gr \theta + \left( r_3M + \frac{1}{K_p} \right) u^{(e)} - P \right] \right\} dy = 0
\]

**Step-2: derivation of the element equation.** In this step by taking the linear solution to the component \( y \in [y_j, y_k] \) and the basis functions which are in this stage, the linear solution to the component \( y \in [y_j, y_k] \) and the basis functions, which are taken into consideration.

\[
u^{(e)} = N^{(e)} \psi^{(e)}, \text{ here } N^{(e)} = [N_j, N_k], \psi^{(e)} = [u_j, u_k]^T \text{ and } N_j = \frac{(y - y_j)}{(y_k - y_j)}, N_k = \frac{(y - y_k)}{(y_k - y_j)}
\]

Incorporating Eq. (15),

\[
\int_{y}^{y_k} \left\{ \left[ r_1 \left[ N_j N_j' N_k N_k' \right] \left[ u_j \right] + \left[ N_j N_k N_k N_k' \right] \left[ u_j \right] + \left( r_3M + \frac{1}{K_p} \right) \left[ N_j N_k N_k N_k' \right] \left[ u_j \right] \right] \right\} dy = P \left[ u_j \right]
\]

By reducing the above equation, we get:

\[
\frac{r_1}{L} \left[ \begin{array}{cc} 1 & -1 \\ -1 & 1 \end{array} \right] \left[ \begin{array}{c} u_j \\ u_k \end{array} \right] + \frac{L}{6} \left[ \begin{array}{cc} 2 & 1 \\ 1 & 2 \end{array} \right] \left[ \begin{array}{c} u_j \\ u_k \end{array} \right] + \left( r_3M + \frac{1}{K_p} \right) \left[ \begin{array}{cc} -1 & 1 \\ -1 & 1 \end{array} \right] \left[ \begin{array}{c} u_j \\ u_k \end{array} \right] = P.
\]

**Step-3: assemble the element equations.** The following may be accomplished by assembling the element equations for consecutive components \( y_{i-1} \leq y \leq y_i \) and \( y_i \leq y \leq y_{i+1} \) in the following stages.
\[
\frac{r_1}{(\rho \sigma)^2} \begin{bmatrix}
1 & -1 & 0 \\
-1 & 2 & -1 \\
0 & -1 & 1
\end{bmatrix} \begin{bmatrix}
u_{i-1} \\
u_i \\
u_{i+1}
\end{bmatrix} + \frac{1}{6} \begin{bmatrix}
1 & 2 & 1 \\
1 & 4 & 1 \\
0 & 1 & 2
\end{bmatrix} \begin{bmatrix}
u_{i-1} \\
u_i \\
u_{i+1}
\end{bmatrix} + \frac{r_3 M + \frac{1}{\kappa_p}}{2 \rho \sigma^{*} } \begin{bmatrix}
-1 & 1 & 0 \\
-1 & 0 & 1 \\
0 & -1 & 1
\end{bmatrix} \begin{bmatrix}
u_{i-1} \\
u_i \\
u_{i+1}
\end{bmatrix} = P
\] (17)

After setting \(i^*\) to 0 in the specified node row, the change pattern with \(i^* = h\) in Eq. (17) is

\[
\frac{1}{6} [u_{i-1}^* + 4u_i^* + u_{i+1}^*] + \frac{r_1}{(\rho \sigma)^2} [-u_{i-1} + 2u_i - u_{i+1}] + \frac{r_3 M + \frac{1}{\kappa_p}}{2 \rho \sigma^{*} } [-u_{i-1} + u_{i+1}] = P^*
\]

The utilization of trapezoidal rule produces the Crank–Nicholson equations systems:

\[
A_1 u_{i-1}^{n+1} + A_2 u_i^{n+1} + A_3 u_{i+1}^{n+1} = A_4 u_{i-1}^n + A_5 u_i^n + A_6 u_{i+1}^n + P^n
\] (18)

where

\[
A1 = (2) - (6 * r * r1) + \left( k * \left( r_3 M + \frac{1}{\kappa_p}\right) \right); A2 = (8) + (12 * r * r1) + \left( 4 * k * \left( r_1 M + \frac{1}{\kappa_p}\right) \right); A3 = (2) - (6 * r * r1) + \left( k * \left( r_3 M + \frac{1}{\kappa_p}\right) \right); A4 = (8) - (12 * r * r1) - \left( 4 * k * \left( r_1 M + \frac{1}{\kappa_p}\right) \right); A5 = (2) + (6 * r * r1) - \left( k * \left( r_3 M + \frac{1}{\kappa_p}\right) \right); A6 = (2) + (6 * r * r1) - \left( k * \left( r_3 M + \frac{1}{\kappa_p}\right) \right)
\]

The same process is applied to the Eq. (11) obtained

\[
G_1 u_{i-1}^{n+1} + G_2 u_i^{n+1} + G_3 u_{i+1}^{n+1} = G_4 u_{i-1}^n + G_5 u_i^n + G_6 u_{i+1}^n
\]

The set of equations is obtained from the boundary restrictions (12) in Eqs. (17, 18) where \(A_1X_i = B_i\) stands in place of for \(i(i) = 3, A_1X_i\) and \(B_i\) as matrices. Applying the Thomas algorithm with 10^{-6} accuracy via MATLAB-code execution yields the necessary numerical solutions.

The wall shear stress, \(\tau\), and the thermal transmission rate are of great relevance in many technological contexts.

Skin friction (also known as shear stress) at the wall can be determined by:

\[
\tau = \frac{\partial u}{\partial \xi} \bigg|_{\xi=0}
\]

The heat transmission coefficient at the wall, expressed as a Nusselt number (Nu) using the following formula

\[
Nu = \frac{\partial \theta}{\partial \xi} \bigg|_{\xi=0}
\]

Outcomes and analysis

The managing parameters like heat generation/absorption \(Q\), magnetic \(M\), radiation \(R\), volume fraction \(\phi\), porosity \(K\), Grashof number \(Gr\), coefficient of exponent \(a\), Eckert number \(Ec\), and time \(t\) for two nanoparticles \(Cu-Water\) and \(TiO_2-Water\) upon the non-dimensional distributions of velocity \(u(\xi)\) and temperature \(\theta(\xi)\) are examined along with \(\xi\). The smooth lines are plotted to measure the effects of the \(Cu-Water\) nanoparticle, whereas the dotted lines for \(TiO_2-Water\).

The effects of the heat absorption \(Q < 0\) on the non-dimensional temperature \(\theta(\xi)\) profile are delineated in Fig. 2 when \(K = Ec = 0\). It is depicted in Fig. 2 that when \(Q = 0\), the profile has obtained its maximum value and gradually decreases when \(Q < 0\). Basically, \(Q < 0\) behaves like a heat sink; therefore, escalating \(Q < 0\) causes a deduction in the temperature due to the energy absorption during the heat sink process. In the same manner, a rising of fluid temperature causes a flow toward the plate as a result of the thermal buoyancy forces. Since the thickness of the momentum boundary layer is decreasing, the velocity is also decreasing as a result. It has also been seen that the velocity rises with the flow of time. The impression of \(M\) upon \(u(\xi)\) for \(Cu-Water\) and \(TiO_2-Water\) are portrayed in Fig. 3. This figure shows that the velocity profile has achieved its highest value in the non-existence of a magnetic region, i.e., when \(M = 0\). Besides, the profile decays when \(M \neq 0\). The escalation in the parameter \(M\) leads to the existence of the Lorentzian force, which shows a retarding behavior against the flow behavior. So, the Lorentz force opposes the fluid motion which consequently decreases the boundary layer thickness and velocity distribution. Also, the increase in magnetic parameter upsurges the frictional forces between the particles of the fluids. That’s why the velocity distribution is lower for higher magnetic factor. The decrease for \(TiO_2-Water\) is slightly higher. Figure 4 is captured to predict the impression of \(K\) on \(u(\xi)\) for

both nanofluid particles (Cu – Water, TiO\(_2\) – Water). It is demonstrated from Fig. that the fluid velocity rises for increasing \( R \). The rise for Cu – Water is more extensive. Figure 5 is depicted the impression of \( \phi \) upon \( \theta (\xi) \) profile for Cu – Water and TiO\(_2\) – Water. It is examined from Fig. 5 that the increment in \( \phi \) leads to an escalation in \( \theta (\xi) \), and this escalation is a little more extensive for Cu – Water. The cause of this behavior is that intermolecular interactions between the nanoparticles weaken with escalating the parameter \( \phi \). Subsequently, the escalation of the thermal boundary layer thickness takes effect. Due to this fact, the temperature grows. Figure 6 measures the impact of \( K \) on \( u(\xi) \) for both nanofluid particles (Cu – Water, TiO\(_2\) – Water). The fluid velocity decays as the parameter \( K \) grows. It is described physically as the regime becoming more porous as the parameter \( K \) increases. The Darcian force’s strength decreases in this manner, slowing the mobility of the fluid’s molecule particles. Consequently, the decrement of fluid velocity appears. The decrease for TiO\(_2\) – Water is slightly more than from Cu – Water. The impact of Grashoff’s number \( Gr \) upon a non-dimensional velocity profile \( u(\xi) \) is measured for Cu – Water, TiO\(_2\) – Water. The profile is experienced increasing along \( \xi \) for higher estimations of the parameter \( Gr \). Where \( Gr > 0 \) means the cool surface of the plate moreover \( Gr < 0 \) signifies the hot surface of the plate. This is obvious from Fig. 7 that the cool surface increases the fluid velocity, whereas the hot surface decreases it. It is further seen that when \( Gr < 0 \) the decrease for Cu – Water is higher but when \( Gr > 0 \) the increase for Cu – Water is larger than from TiO\(_2\) – Water. The impact of \( a \) on \( u(\xi) \) for Cu – Water, TiO\(_2\) – Water is depicted in Fig. 8. The profile \( u(\xi) \) grows for higher estimations of the parameter \( a \).
From this description, from the definition that as the parameter $a$ escalates the characteristic of the exponential function too escalates quickly. This can be observed from Fig. that when the parameter $a$ rises the velocity profile also rises within the domain for $Cu - Water, TiO_2 - Water$. This rise is marginally greater for $Cu - Water$. The outcome of $Ec$ upon $u(\xi)$ and $\theta(\xi)$ outlines are summarized in Figs. 9 and 10 both nanofluid particles ($Cu - Water, TiO_2 - Water$). It is experienced from these Figs. 9 and 10. That both profiles escalate for growing estimations of the parameter $Ec$. The viscous dissipation impact is predicted by the Eckert number $Ec$. As the $Ec$ grows the kinetic energy is converted into heat energy. Consequently, the thermal conductivity is enhanced and the fluid temperature elevates. The fluid velocity and temperature are marginally higher for $Cu - Water$ than from $TiO_2 - Water$ when the parameter $Ec$ rises. Figures 11, 12 and 13 are plotted to elucidate the impacts of $t$ and $Q$ of $u(\xi)$ and $\theta(\xi)$ outlines for $Cu - Water, TiO_2 - Water$. It is examined from Figs. 11, 12, 13 that the velocity and temperature increase for the parameters $t$ and $Q$ (see Figs. 11, 12). If $Q < 0$ then this means the absorption process and behaves like a heat sink which reduces the velocity and the temperature. Whereas, if $Q > 0$ then this leads to a generation process and it acts like a heat source that increases velocity and temperature.

The numerical values of the physical quantities like skin friction coefficient ($\tau$) and local Nusselt number ($Nu$) are calculated for the diverse ranges of the parameters $M, \phi, Gr, Pr, K, R, Ec, t, a$ and $Q$. These physical quantities are calculated for both nanofluid particles, i.e. for $Cu$ and $TiO_2$ in Table 2.
Conclusions

Study the heat transmission characteristics of electrically conducting nanofluid flow by considering the solid volume fraction of nanoparticles Cu and TiO$_2$ in the existence of viscous dissipation and radiation over a porous plate. The leading PDEs are tackled via the Galerkin weighted residual numerical approach. The influence of pertinent parameters is measured on the non-dimensional boundary layer distributions of velocity and temperature. Thus following concluding remarks can be depicted:

- The fluid velocity is efficiently controlled with a magnetic field and porous medium effects.
- The fluid velocity enhances with the rising level of radiation, Grashoff’s number, exponent coefficient, Eckert number, heat generation/absorption, and time.
• The fluid temperature is decreased during the heat absorption process.
• The consequence of the solid volume fraction, Eckert number, and heat generation is to escalate the fluid temperature.
• The heat transfer rate is not significantly affected by the magnetic field for Cu and TiO₂.
• The thermal radiation and viscous dissipation decay the heat transfer rate.

Finally, further research can be considered by incorporating different nanoparticles in the fluid to study their thermal enhancement under a vertical plate for hybrid and ternary hybrid nanofluids. The G-FEM could be a potential utilization for future science and technology challenges⁴⁴–⁵⁸.
Figure 9. $Ec$ vs $u$.

Figure 10. $Ec$ vs $\theta$. 
**Figure 11.** $t$ vs $u$.

**Figure 12.** $Q$ vs $u$. 

**Equations for Figures 11 and 12:**

For Figure 11:
- $R = 2; \ Gr = 2; \ \phi = 0.001; \ Pr = 6.2; \ K = 0.5; \ Q = 2; \ a = 0.5; \ Ec = 0.02$
- Smooth Lines: Cu-Water
- Dashed Lines: TiO$_2$-Water
- $t = 0.1, 0.3, 0.5$

For Figure 12:
- $R = 2; \ Gr = 2; \ \phi = 0.001; \ Pr = 6.2; \ M = 1; \ t = 0.1; \ K = 0.5; \ a = 0.5; \ Ec = 0.02$
- Smooth Lines: Cu-Water
- Dashed Lines: TiO$_2$-Water
- $Q = -2, -1, 0, 1, 2$
