RECTIFICATION OF ALGEBRAS AND MODULES

VLADIMIR HINICH

Abstract. Let $O$ be a topological (colored) operad. The Lurie $\infty$-category of $O$-algebras with values in (\infty-category of) complexes is compared to the $\infty$-category underlying the model category of (classical) dg $O$-algebras. This can be interpreted as a "rectification" result for Lurie operad algebras. A similar result is obtained for modules over operad algebras, as well as for algebras over topological PROPs.

1. Introduction

1.1. Operad algebras. In this paper we compare two notions of operad algebra with values in complexes. Let $O$ be a topological colored operad. The functor of singular chains with coefficients in a commutative ring $k$ converts $O$ into an operad in the category of complexes, so that one has the category $\text{Alg}_O(C(k))$ of $O$-algebras in $C(k)$ in the "conventional" sense: its objects are complexes $A \in C(k)$ together with operations

$$C_*(O(n), k) \otimes A^\otimes n \to A$$

satisfying the standard compatibilities.

The category $\text{Alg}_O(C(k))$ has (sometimes) a model category structure with quasiisomorphisms as weak equivalences and surjective maps as fibrations. Sometimes it does not have such model structure. In any case, one can find a quasiisomorphism of dg operads $R \to C_*(O)$ such that the category of $R$-algebras has a model structure; moreover, under a mild extra requirement, the model category $\text{Alg}_R(C(k))$ is independent, up to Quillen equivalence, of the dg operad $R$. The operad $R$ satisfying the above properties will be called homotopically sound, see [2.4.6] below.

A topological operad $O$ defines, on the other hand, an $\infty$-operad $O^{\otimes}$ in the sense of Lurie, [L.HA], Section 2, and an $\infty$-category of algebras $\text{Alg}_O^\otimes(QC(k))$ with values in the SM $\infty$-category $QC(k)$ which is the $\infty$-category version of the derived category of $k$-modules. Our main result Theorem 4.1.1 claims that, given a quasiisomorphism of operads $R \to C_*(O)$ with $R$ homotopically sound\footnote{any operad is homotopically sound if, for instance, $k$ is a field of characteristic zero.} the $\infty$-category $\text{Alg}_O^\otimes(QC(k))$ is equivalent to the $\infty$-category underlying the "classical" model category $\text{Alg}_R(C(k))$. This can be interpreted as a rectification result:
any Lurie $\mathcal{O}$-algebra with values in $\mathcal{QC}(k)$ can be presented by a strict $R$-algebra. In good cases, when $C_*(\mathcal{O})$ is homotopically sound, any Lurie $\mathcal{O}$-algebra can be presented by a strict $\mathcal{O}$-algebra with values in $C(k)$.

We feel this is an important (though not unexpected) result: the notion of operad algebra in Lurie theory is very flexible; however, an algebra over an $\infty$-operad is defined by a huge collection of coherence data which is difficult to specify. The description of $\text{Alg}_{\mathcal{O}}(\mathcal{QC}(k))$ as a nerve of a model category allows one to present $\mathcal{O}_{\infty}$-algebras in $\mathcal{QC}(k)$ and their diagrams by strict $\mathcal{O}$-algebras in complexes.

1.1.1. The mere formulation of Theorem 4.1.1 requires a model category structure on the category of algebras over a color dg operad. An account of the relevant theory is presented in Section 2. The results of this section are mostly well-known, at least for colorless operads. Our approach here is very close to the earlier colorless version [H].

Note that there exists a very general result by C. Berger and I. Moerdijk, [BM2], on model structure for algebras over color operads. Unfortunately, we were unable to deduce from their result that all dg operads are admissible in case $k \supset \mathbb{Q}$. This is why we felt it important to present the colored version of the notion of $\Sigma$-splitness used in [H].

1.1.2. Dold-Kan. As we mentioned above, a simplicial operad can be converted, via the normalized chains functor, into a dg operad. This is due to the fact that the normalized chains functor

$$C_* : \text{sSet} \longrightarrow C(k)$$

is lax symmetric monoidal, via Eilenberg-MacLane map.

Were it really symmetric monoidal, any strict operad algebra over $\mathcal{O}$ with values in $C(k)$ would automatically define an $\mathcal{O}$-algebra in the sense of Lurie. In real life this is ”almost so” — the functor $C_*$ induces an adjoint pair between the symmetric monoidal $\infty$-categories $\text{Cat}_\infty$ and $\text{dgCat}$.

This ”almost so” has to be explained, and we do so in Section 3 which precedes the rectification theorem.

1.1.3. The proof of Theorem 4.1.1 follows the idea of Lurie’s Theorem 4.1.4.4 of [L.HA] where a similar result for associative algebras with values in a combinatorial monoidal model category is proven.

1.2. Algebras over PROPs. Theorem 4.1.1 allows one to (partially) rectify algebras more general than algebras over operads, such as, for instance, associative bialgebras.

These are algebras over PROPs, that is, symmetric monoidal functors from a certain symmetric monoidal category designed to describe the necessary structure (PROP), to the category of complexes.
A topological PROP $P$ gives rise to a SM $\infty$-category $P^\otimes$; this leads to the notion of $P$-algebra with values in complexes as a SM functor $P^\otimes \to QC(k)^\otimes$.

We do not expect such algebras to be always presentable by strict $P$-algebras in complexes. One can, however, slightly generalize the notion of strict dg algebra over a PROP — allowing lax symmetric monoidal functors to complexes which are "homotopy SM", see Definition 4.4.1.

Our rectification theorem 4.1.1 implies easily the equivalence of two approaches, see Corollary 4.4.4.

1.3. Modules. The notion of module over an operad algebra is very straightforward in the "classical" theory. We describe a construction which assigns to a topological operad $\mathcal{O}$ another operad $\mathcal{M}\mathcal{O}$ whose algebras are pairs $(A, M)$ where $A$ is an $\mathcal{O}$-algebra and $M$ is an $A$-module. A similar construction can be easily defined in the world of $\infty$-operads as well.

J. Lurie suggests another notion of module over an operad algebra. Similarly to the cases of commutative or associative algebras where modules (or bimodules) form a symmetric monoidal (or simply monoidal) category, his version of the $\infty$-category of modules over a fixed $\infty$-operad algebra $A$ has an $\mathcal{O}$-monoidal structure. To have such nicely behaved notion, one has to require some very special properties from $\mathcal{O}$ — it has to be coherent, see [L.HA], Sect. 3.

In Appendix B we prove that our definition of module coincides with the one suggested by Lurie (with discarded $\mathcal{O}$-monoidal structure). Our rectification result easily implies the rectification for modules, see Corollary 5.2.3.

1.4. SM adjunction. Appendix A deals with adjunction between two (or more) symmetric monoidal $\infty$-categories. It turns out that if any of the adjunctions is a lax SM functor, all others automatically acquire the same structure. This generalizes a well-known observation for conventional symmetric monoidal categories that the functor right adjoint to a SM functor, is necessarily lax. We believe that this is an important fact in its own. In this paper we use it to construct the functor from strict operad algebras to algebras over the corresponding $\infty$-operad.

Appendix B contains some technical details of the comparison between two notions of module.

1.5. Acknowledgements. Parts of this paper were written during author’s visit to MIT and IHES. I am grateful to these institutions for hospitality and excellent working conditions. I am very grateful to J. Lurie for several useful conversations.

2. Models for algebras

2.1. Introduction. In this section we present an account of the model category structure on algebras over colored operads. The results described in this section

---

2 A very close notion was used by K. Costello in [C] (h-split symmetric monoidal functors).
are mostly well-known, for the colorless case see [H, H.V, BM1], and for the colored case [BM2] (Berger and Moerdijk consider more general algebras with values in any model category).

Having in mind applications to dg algebras, we wanted to make sure the important case of algebras in characteristic zero would be covered. The only proof we are aware of in the colorless case is via the notion of Σ-split operads presented in [H]. This is why we spend some time to give a colored version of this notion.

We also use this section as an opportunity to fix notation for colored operads.

2.2. Colored operads. Fix a symmetric monoidal category $\mathcal{C}$. A colored operad $O$ in $\mathcal{C}$ consists of the following data.

1. A set $[O]$ (the set of colors of $O$).
2. An object $O(c, d)$ of $\mathcal{C}$ (of operations) given for each collection of colors $c : I \to [O]$ ($I$ is a finite set) and a color $d \in [O]$.
3. A composition map defined for each map of finite sets $f : I \to J$, with collections of objects $c : I \to [O]$, $d : J \to [O]$, $e \in [O]$. This is a map

\[
O(d, e) \otimes \bigotimes_{j \in J} O(c_j, d(j)) \longrightarrow O(c, e),
\]

where $c_j$ denotes the restriction of $c : I \to [O]$ to $I_j = f^{-1}(j)$.

The composition maps are required to satisfy the obvious associativity conditions. We also assume the existence of unit elements $1_c \in O(\{c\}, c)$ for each $c \in [O]$.

Colored operads are also known under other names as ”multicategories” or ”pseudo-tensor categories”. The first name is self-explanatory. The reason for the second one (due to Beilinson) is that colored operads can be assigned to symmetric monoidal categories. Thus, colored operads can be seen as the generalizations of symmetric monoidal categories. Here are the details.

Let $\mathcal{D}$ be a symmetric monoidal category enriched over $\mathcal{C}$ (The case $\mathcal{C} = \text{Set}$ is as interesting as any other). We can put $[\mathcal{D}] = \text{Ob}(\mathcal{D})$ and define $\mathcal{D}(c, d) = \text{Hom}_{\mathcal{D}}(\bigotimes_{i \in I} c(i), d)$. This yields a colored operad in $\mathcal{C}$.

It is not difficult to understand when a colored operad $O$ comes in the above described manner from a symmetric monoidal category. First of all, any colored operad $O$ has an underlying category (also enriched over $\mathcal{C}$) denoted $O_1$ in the sequel. If we wish $O$ to come from a symmetric monoidal (SM) category, the functors $d \mapsto O(c, d)$ should be representable for each $c : I \to [O]$. This condition is not yet sufficient: assuming all functors above are representable by the objects denoted as $\bigotimes_{i \in I} c(i)$, we obtain for each map $f : I \to J$ of finite sets a canonical map

\[
\bigotimes_{i \in I} c(i) \longrightarrow \bigotimes_{j \in J} (\bigotimes_{i \in I} c(i)).
\]
If these maps are isomorphisms, our colored operad \( \mathcal{O} \) comes from a SM category (uniquely defined up to equivalence).

### 2.2.1. Planar versions.
If one replaces finite sets with totally ordered finite sets and the maps of finite sets with the monotone maps, we get a multicolor notion of planar (or asymmetric) operad. This notion generalizes the notion of monoidal category in the same way as the notion of colored operad generalizes the notion of SM category.

### 2.2.2. Maps of operads.
Given two colored operads \( \mathcal{P} \) and \( \mathcal{Q} \), a map of operads \( f : \mathcal{P} \to \mathcal{Q} \) is defined as a map \( f : [\mathcal{P}] \to [\mathcal{Q}] \) together with a compatible collection of maps

\[
\mathcal{P}(c, d) \to \mathcal{P}(f \circ c, f(d))
\]

for each \( c : I \to [M] \).

Compatibility means that the above maps preserve units and are compatible with compositions.

If \( \mathcal{P} \) and \( \mathcal{Q} \) are the operads corresponding to SM categories, a map of operads \( f : \mathcal{P} \to \mathcal{Q} \) is what is usually called a lax SM functor.

### 2.2.3. SM functors.
In a more detail, let \( \mathcal{P} \) and \( \mathcal{Q} \) be SM categories and let \( f : \mathcal{P} \to \mathcal{Q} \) be a map of the corresponding colored operads. This means that a compatible collection

\[
\text{Hom}(\otimes_{i \in I} a_i, b) \to \text{Hom}(\otimes_{i \in I} f(a_i), f(b))
\]

is given. By naturality, this is the same as a compatible collection of morphisms

\[
\otimes_{i \in I} f(a_i) \longrightarrow f(\otimes_{i \in I} a_i).
\]  

This is what is usually called a lax SM functor. A map of operads \( f : \mathcal{P} \longrightarrow \mathcal{Q} \) is called a SM functor if the maps (3) are isomorphisms.

### 2.2.4. Algebras.
We assume that the base symmetric monoidal category \( \mathcal{C} \) admits colimits and the tensor product commutes with colimits along each one of the arguments.

Let \( \mathcal{O} \) be a colored operad in \( \mathcal{C} \). An \( \mathcal{O} \)-algebra in \( \mathcal{C} \) is just a map of operads \( A : \mathcal{O} \to \mathcal{C} \).

The category of \( \mathcal{O} \)-algebras in \( \mathcal{C} \) is denoted as \( \text{Alg}_{\mathcal{O}}(\mathcal{C}) \) or just \( \text{Alg}_{\mathcal{O}} \) if \( \mathcal{C} \) can be understood from the context.

The following theorem is very standard.

---

3By the way, defining a SM category as a colored operad satisfying the above properties, allows one not to care about associativity or commutativity constraints.

4In what follows we will say “operads” and “colorless operads” instead of “colored operads” and “operads”.

---
2.2.5. Theorem. Let $f : P \to Q$ be a map of operads. There is a pair of adjoint functors

$$f_! : \text{Alg}_P \leftrightarrow \text{Alg}_Q : f^*$$

where $f^*$ is the forgetful functor, assigning to $A : Q \to C$ the composition $f^*(X) = A \circ f : P \to Q \to C$.

In the special case where $P = [Q]$ is the operad with the same colors as $Q$ and with no nontrivial operations, the functor $f_!$ is the free algebra functor which is worth of a more detailed description.

Let $V : [\mathcal{O}] \to C$ be a collection of objects of $C$ numbered by the colors. The free algebra $F_{\mathcal{O}}(V)$ is the collection of objects $F_{\mathcal{O}}(V)_d, d \in [\mathcal{O}]$, described as follows. Collections $c : I \to [\mathcal{O}]$ form a groupoid denoted $\text{Fin}/[\mathcal{O}]$. To each $c \in \text{Fin}/[\mathcal{O}]$ we assign the object

$$(4) \quad \mathcal{O}(c, d) \otimes \bigotimes_{i \in I} V_{c(i)}.$$ 

This gives rise to a functor $\mathfrak{F}(V)_d : \text{Fin}/[\mathcal{O}] \to C$; its colimit is the component $\mathfrak{F}_{\mathcal{O}}(V)_d$ of the free $\mathcal{O}$-algebra generated by $V$.

The functor $f_!$ carries the free $P$-algebra generated by a collection $V = \{V_c\}_{c \in \mathcal{P}}$ to the free $Q$-algebra generated by the collection $d \mapsto \coprod_{c \in \mathcal{P} : f(c) = d} V_d$.

2.3. DG version. From now on we fix a commutative ring $k$ and we study operads and algebras with values in the category $C(k)$ of complexes over $k$.

First of all, the category of complexes $C(k)$ admits a model structure, with quasiisomorphisms as weak equivalences and surjective maps as fibrations, see, for example, [H].

Cofibrant objects in this model structure are the retracts of the complexes constructed by joining consecutive generators with a prescribed value of their differential.

For a large class of dg operads a model category structure on $\text{Alg}_{\mathcal{O}}(C(k))$ can be defined using the adjoint pair of functors

$$f_! : \text{Alg}_{\mathcal{O}}(C(k)) \leftrightarrow \text{Alg}_{\mathcal{O}}(C(k)) : \mathfrak{G},$$

where $\mathfrak{G}$ is the forgetful functor and $\mathfrak{F}_{\mathcal{O}}$ is the free $\mathcal{O}$-algebra functor.

A map of $\mathcal{O}$-algebras $f : A \to B$ is called a weak equivalence (resp., a fibration) if $\mathfrak{G}(f)$ is a weak equivalence (resp., a fibration). In other words, $f$ is a weak equivalence if for each color $c \in [\mathcal{O}]$ the map $A_c \to B_c$ is a quasiisomorphism of complexes. It is a fibration if all maps $A_c \to B_c$ are surjective. It is called a cofibration if it satisfies the left lifting property with respect to all trivial fibrations.

2.3.1. Definition. An operad $\mathcal{O}$ in $C(k)$ is called admissible if the category of algebras $\text{Alg}_{\mathcal{O}}(C(k))$ admits a model category structure determined by weak equivalences and fibrations defined as above.
The operads with a fixed collection of colors $K$ can be described as the algebras over an appropriate operad whose colors are the finite collections of the elements of $K$. This allows one to define, for instance, cofibrant operads.

One has (see [BM2], colorless case [H.V])

2.3.2. **Proposition.** A cofibrant operad is admissible.

Another class of admissible operads ($\Sigma$-split operads) is described in Subsection 2.5. It includes, for instance, all planar operads, or all operads over $k \supset \mathbb{Q}$.

Note the following criterion of admissibility.

2.3.3. **Theorem.** An operad $\mathcal{O}$ in $\mathcal{C}(k)$ is admissible if and only if for any $\mathcal{O}$-algebra $A$ and for any collection of contractible cofibrant complexes $M = \{M_c\}$, $c \in [\mathcal{O}]$, the natural map

\[
A \longrightarrow A \coprod \mathbb{F}_\mathcal{O}(M)
\]

is a weak equivalence.

The proof for colorless operads is given in [H]. The same reasoning proves the colored case. \hfill \square

One immediately sees that it is sufficient to check that (6) is a weak equivalence for $M = \{M_c\}$ with $M_c = 0$ for $c \neq c_0$, and $M_{c_0}$ contractible cofibrant.

2.4. **Change of operad.** Recall that a map $f : \mathcal{P} \longrightarrow \mathcal{Q}$ of operads gives rise to a pair of adjoint functors

\[
f_! : \text{Alg}_\mathcal{P} \longleftrightarrow \text{Alg}_\mathcal{Q} : f^*
\]

where $f^*$ forgets a part of the structure. One has the following

2.4.1. **Theorem.** Assume $\mathcal{P}$ and $\mathcal{Q}$ are admissible. Then the pair of adjoint functors $(f_!, f^*)$ is a Quillen pair.

**Proof.** The forgetful functor obviously preserves fibrations (surjective maps) and trivial fibrations (surjective quasiisomorphisms). \hfill \square

One can expect the pair $(f_!, f^*)$ to be a Quillen equivalence under some favorable conditions.

Recall that for a dg operad $\mathcal{O}$ we denote by $\mathcal{O}_1$ the underlying dg category which remembers only unary operations of $\mathcal{O}$. Passing to the zero cohomology of all Hom complexes, we get a category $H^0(\mathcal{O}_1)$.

2.4.2. **Definition.** 1. A map $f : \mathcal{P} \rightarrow \mathcal{Q}$ is called a weak equivalence if

a. For each $c : I \rightarrow [\mathcal{P}]$ and $d \in [\mathcal{P}]$ the morphism $\mathcal{P}(c, d) \rightarrow \mathcal{Q}(f \circ c, f(d))$ is a quasiisomorphism.

b. The functor $H^0(f_1) : H^0(\mathcal{P}_1) \rightarrow H^0(\mathcal{Q}_1)$ is an equivalence of categories.
2. A map $f : \mathcal{P} \to \mathcal{Q}$ is a strong equivalence if instead of (a) the following stronger condition is fulfilled.

\[ a' \text{. Let } c : I \to [\mathcal{P}] \text{ be a collection of colors and } d \in [\mathcal{P}] \text{. Choose a decomposition } c = c' \circ p \]

\[ I \xrightarrow{p} J \xrightarrow{c'} [\mathcal{P}] \]

with $p$ surjective, and let $G$ be the subgroup of automorphisms of $I$ over $J$. The map

\[ \mathcal{P}(c, d) \otimes_G k \to \mathcal{Q}(f \circ c, f(d)) \otimes_G k \]

is a quasiisomorphism for all $c, d$ and $p$.

2.4.3. Definition. An operad $\mathcal{O}$ in $C(k)$ is called $\Sigma$-cofibrant if for each $c : I \to [\mathcal{O}]$ and $d \in [\mathcal{O}]$ with $G$ the group of automorphisms of $c$, the complex $\mathcal{O}(c, d)$ is a cofibrant complex of $G$-modules.

2.4.4. Remark. Weak equivalence of operads implies their strong equivalence in case they are $\Sigma$-cofibrant.

2.4.5. Theorem. A strong equivalence of admissible operads $f : \mathcal{P} \to \mathcal{Q}$ gives rise to a Quillen equivalence $(f_!, f^*)$.

The above observations lead us to the following definition.

2.4.6. Definition. An operad $\mathcal{O}$ is called homotopically sound if it is admissible and $\Sigma$-cofibrant.

One can define therefore homotopy $\mathcal{O}$-algebras as algebras over an operad which is a homotopically sound replacement of $\mathcal{O}$.

2.5. $\Sigma$-split operads. In this subsection we present another class of admissible operads.

Let $\mathcal{O}$ be an operad. We define a new operad $\mathcal{O}^\Sigma$ which "remembers the order of operands". The colors of $\mathcal{O}^\Sigma$ and of $\mathcal{O}$ are the same: $[\mathcal{O}^\Sigma] = [\mathcal{O}]$.

Let $c : I \to [\mathcal{O}]$ be a collection of colors of $\mathcal{O}$ numbered by a finite set $I$ and let $d \in [\mathcal{O}]$. We define

\[ \mathcal{O}^\Sigma(c, d) = \bigoplus_{\theta : I \simeq \{n\}} \mathcal{O}(c, d), \]

where $\{n\} = \{1, \ldots, n\}$ is the standard (totally ordered) $n$-element set. Note that the choice of $\theta$ is equivalent to the choice of a total order on $I$.

Let us define the composition. Let $f : I \to J$ be a map of sets and let $c : I \to [\mathcal{O}]$ and $d : J \to [\mathcal{O}]$ be collections. The map

\[ \mathcal{O}^\Sigma(d, e) \times \prod_j \mathcal{O}^\Sigma(c_j, d(j)) \to \mathcal{O}^\Sigma(c, e) \]
is defined as follows. Choice of a total order on $J$ together with a choice of total orders on each fiber $f^{-1}(j)$ defines a lexicographical total order on $I$: if two elements of $I$ belong to different fibers, we compare the fibers, and if they belong to the same fiber, we compare them inside the fiber. With the described above choice of the orderings, the corresponding component of the map (11) is given by the composition (11) for $O$.

For example, if $O$ is the operad for commutative algebras, $O_\Sigma$ is the operad for associative algebras.

2.5.1. Remark. The operation $O \mapsto O_\Sigma$ described above can be better understood in the context of planar operads. One has an obvious forgetful functor $O \mapsto O^f$ assigning to an operad its planar counterpart. The functor $\sharp$ admits a left adjoint functor which we denote $O \mapsto O_\Sigma$; if $O$ is a planar operad, the operad $O_\Sigma$ is defined by the formula

$$O_\Sigma(c,d) = \bigoplus_{\theta : I \to \langle n \rangle} O((c, \theta), d),$$

where the pair $(c, \theta)$ describes a colored collection $c$ numbered by the totally ordered set $(I, \theta)$.

The endofunctor $O \mapsto O_\Sigma$ described in the paper is in fact the composition of this pair of adjoint functors.

2.5.2. One has a canonical map

$$\pi : O_\Sigma \longrightarrow O$$

summing up the components corresponding to different orderings (this is the standard adjunction map in terms of the remark above).

One defines $\Sigma$-splitting as a collection of splittings $t = t^{c,d} : O(c, d) \longrightarrow O_\Sigma(c, d)$ of the canonical map $\pi$ described above, satisfying the properties (SPL), (INV), (COM) which will be specified later on. We will usually omit the superscript $(c, d)$ from the notation.

A $\Sigma$-splitting $t$ is defined by a collection of its components $t_\theta : O(c, d) \rightarrow O(c, d)$ numbered by different orderings of $I$.

The first two requirements for $\Sigma$-splitting are

(SPL) The map $t$ splits $\pi$, that is $\sum_\theta t_\theta = \text{id}$.

(INV) For any isomorphism $f : c' \rightarrow c$ (that is, a bijection $f : I' \rightarrow I$ satisfying $c' = c \circ f$) the induced isomorphism $f^* : O(c, d) \rightarrow O(c', d)$ commutes with $t$. The latter means that

$$f^* \circ t_\theta = t_{\theta f} \circ f^*.$$

The last requirement of $\Sigma$-splitness is a weak form of compatibility of the splitting with the compositions.
Let \( c : I \to [\emptyset] \), \( d : J \to [\emptyset] \), \( a : K \to [\emptyset] \), \( a' : K' \to [\emptyset] \) be finite collections in \( \emptyset \). Let \( f : I \to J \) be a map of finite sets and let \( \phi : a \to a' \) be an isomorphism of collections (that is, a bijection \( \phi : K \to K' \) such that \( a = a' \circ \phi \)).

Gluing the above data, one gets collections \( c \sqcup a : I \sqcup K \to [\emptyset] \) and \( d \sqcup a' : J \sqcup K' \to [\emptyset] \), as well as a map of finite sets \( f \sqcup \phi : I \sqcup K \to J \sqcup K' \).

The requirement (COM) describes a compatibility of the splitting with the composition in \( \emptyset \)

\[
\mathcal{O}(d \sqcup a', e) \otimes \bigotimes_{j \in J} \mathcal{O}(c_j, d(j)) \to \mathcal{O}(c \sqcup a, e)
\]

induced by the morphism \( f \sqcup \phi \).

We are now able to formulate the third requirement of \( \Sigma \)-splittings.

(COM) The following diagram is commutative.

\[
\begin{array}{ccc}
\mathcal{O}(d \sqcup a', e) \otimes \bigotimes_{j \in J} \mathcal{O}(c_j, d(j)) & \to & \mathcal{O}(c \sqcup a, e) \\
\oplus_{\eta: J \sqcup K' \simeq ([|J|]+|K'|)} & & \oplus_{\theta: I \sqcup K' \simeq ([|I|]+|K'|)} \\
\oplus_{k \in K'} \mathcal{O}(d \sqcup a', e) \otimes \bigotimes_{j \in J} \mathcal{O}(c_j, d(j)) & \to & \oplus_{k \in K} \mathcal{O}(c \sqcup a, e)
\end{array}
\]

The upper vertical arrows in the diagram are defined by splitting of \( \mathcal{O}(d \sqcup a', d) \) and of \( \mathcal{O}(c \sqcup a, e) \) respectively. In order to define the lower vertical arrows we will introduce the following notation. For each ordering \( \eta \) of the set \( J \sqcup K' \) we denote by \( \min_{K'}(\eta) \) the smallest element of the subset \( K' \) of \( J \sqcup K' \). In the same manner we define \( \min_K(\theta) \). Now the maps \( q \) send each \( \eta \)-component (resp., \( \theta \)-component) to the corresponding \( \min_{K'}(\eta) \)-component (resp., \( \min_K(\theta) \)-component).

2.5.3. **Remark.** There is another (stronger) version of \( \Sigma \)-splitness where \( q \) is replaced with a projection to the sum over orderings of \( K' \) (resp., of \( K \)). It seems more satisfactory aesthetically; in this formulation the condition (INV) is its special case for \( I = J = \emptyset \).

This stronger version was used in the definition given in [H] for the colorless case.
2.5.4. **Example.** In the case $k \supset Q$ the map

$$t_\theta(m) = \frac{1}{m!} m$$

defines a $\Sigma$-splitting.

2.5.5. **Example.** Let $P$ be a planar color operad and let $\mathcal{O} = P^\Sigma$. The canonical map of asymmetric operads $P \to \mathcal{O}^\Sigma$ defines a map of operads $t : \mathcal{O} \to \mathcal{O}^\Sigma$ splitting the canonical map $\mathcal{O}^\Sigma \to \mathcal{O}$. This map satisfies obviously the conditions (SPL), (INV), (COM).

2.6. **Admissibility of $\Sigma$-split operads.** One has

2.6.1. **Theorem.**

- $\Sigma$-split operads in $C(k)$ are admissible.
- If the components $\mathcal{O}(c, d)$ of a $\Sigma$-split operad $\mathcal{O}$ are cofibrant complexes, $\mathcal{O}$ is homotopically sound.

The second claim of the theorem immediately follows from the first one, as $\mathcal{O}(c, d)$ is a direct summand of $\mathcal{O}^\Sigma(c, d)$ which is cofibrant $\text{Aut}(c)$-complex.

The forgetful functor commutes with filtered colimits. Thus, it is sufficient to check that the map $A \to A \coprod F(H_a)$ is a quasiisomorphism for $H_a$ standard contractible complex Cone(id$_a$)$[d]$ concentrated at a color $a \in [\mathcal{O}]$. The proof of the theorem is given in 2.6.2–2.6.5 below.

2.6.2. **Extending homotopy to a free algebra.** Let $V = \{V_d|d \in [\mathcal{O}]\}$ be a collection of complexes, $\alpha : V \to V$ an endomorphism and $h$ a homotopy of $\alpha$ with id$_V$, that is a degree $-1$ map satisfying the condition

$$dh = \text{id}_V - \alpha.$$

The endomorphism $\alpha$ induces an endomorphism $F_\mathcal{O}(\alpha) : F_\mathcal{O}(V) \to F_\mathcal{O}(V)$; we will present an explicit homotopy between id$_{F_\mathcal{O}(V)}$ and $F_\mathcal{O}(\alpha)$ which we will denote $F_\mathcal{O}(h)$. The homotopy $F_\mathcal{O}(h)$ will be based on a $\Sigma$-splitting of $\mathcal{O}$.

Recall that one has a morphism of operads $\pi : \mathcal{O}^\Sigma \to \mathcal{O}$ identical on the colors, as well as a $\Sigma$-splitting $t : \mathcal{O}(c, d) \to \mathcal{O}^\Sigma(c, d)$.

We are now ready to define a homotopy $H$ on $F_\mathcal{O}(V)$. Recall that $F_\mathcal{O}(V)_d$ is the direct limit of the functor $\mathcal{G}(V)_d$ carrying a collection $c : I \to [\mathcal{O}]$ to

$$\mathcal{G}(V)_d(c) = \mathcal{O}(c, d) \otimes \bigotimes_i V_{c(i)}.$$
We will define a degree \(-1\) endomorphism \(H\) of each separate \(\mathfrak{F}(V)\), \(d(c)\) compatible with the isomorphisms \(c \to c'\) of collections. It is given by the composition

\[
\mathcal{O}(c, d) \otimes \bigotimes_i V_{c(i)} \xrightarrow{t} \bigoplus_{\theta : I \simeq \langle n \rangle} \mathcal{O}(c, d) \otimes \bigotimes_i V_{c(i)} \xrightarrow{S} \bigoplus_{\theta : I \simeq \langle n \rangle} \mathcal{O}(c, d) \otimes \bigotimes_i V_{c(i)},
\]

with the map \(S\) being defined at the \(\theta\)-component as

\[
S_\theta = \sum_i \text{id}_{\mathcal{O}(c, d)} \otimes \alpha^{i-1} \otimes h \otimes \text{id}^{n-i}.
\]

2.6.3. In order to check that the morphism \(A \to A \bigoplus \mathbb{F}_\mathcal{O}(H_a)\) is a quasiisomorphism for \(H_a = \text{Cone}(\text{id}_k)[d]\), one proceeds as follows.

Let \(A' = A \oplus H_a\). Then \(A \bigoplus \mathbb{F}_\mathcal{O}(H_a)\) can be described as the quotient of \(\mathbb{F}_\mathcal{O}(A')\) by the ideal generated by the kernel of the natural map \(\mathbb{F}_\mathcal{O}(A) \to A\).

Let \(\alpha : A' \to A'\) be zero on \(H_a\) and \(\text{id}_A\) on \(A\). Let \(h : A' \to A'\) be the degree \(-1\) map vanishing on \(A\) such that \(dh = \text{id} - \alpha\). Then \(h\) defines a homotopy \(\mathbb{F}_\mathcal{O}(h)\) on \(\mathbb{F}_\mathcal{O}(A')\) extending \(h\).

Let \(J\) the the kernel of the natural projection \(\mathbb{F}_\mathcal{O}(A) \to A\) and let \(J\) be the ideal in \(\mathbb{F}_\mathcal{O}(A')\) generated by \(J\). We check below that \(H(J) \subset J\) and this induces a homotopy on the quotient \(\mathbb{F}_\mathcal{O}(A')/J = A \bigoplus \mathbb{F}_\mathcal{O}(H_a)\).

2.6.4. Action of \(\mathbb{F}_\mathcal{O}(h)\) on \(\mathbb{F}_\mathcal{O}(A')\). Some relevant notation. For \(c : I \to [\emptyset]\) and \(n \geq 0\) we define \(c^{*n} : I \sqcup \langle n \rangle \to [\emptyset]\) by the formula

\[
c^{*n}(i) = c(i) \text{ for } i \in I; \ c^{*n}(k) = a \text{ for } k \in \langle n \rangle;
\]

The \(e\)-component of the free algebra \(\mathbb{F}_\mathcal{O}(A')\) with \(A' = A \oplus H_a\) is the colimit of the complexes

\[
\mathcal{O}(c^{*n}, e) \otimes \bigotimes_i A_{c(i)} \otimes H_a^\otimes^n
\]

The homotopy \(\mathbb{F}_\mathcal{O}(h)\) is defined by the components \(S_\theta\) numbered by the total ordering \(\theta\) of the set \(I \sqcup \langle n \rangle\). Since \(h\) vanishes on \(A\) and \(\alpha\) is identity on \(A\) and vanishes on \(H_a\), the map \(S_\theta\) has form

\[
S_\theta = \text{id}_{\mathcal{O}(c^{*n}, e)} \otimes \text{id}_A \otimes \text{id}^{\otimes k-1} \otimes h \otimes \text{id}^{n-k}
\]

where the homotopy \(h\) is applied to the \(k\)-th component of \(H_a\), with \(k := \min_{\langle n \rangle}(\theta)\).
2.6.5. End of the proof. We keep the notation of 2.6.3.

The ideal $J$ in $\mathbb{F}_O(A')$ generated by $J$, is spanned by the expressions

\begin{equation}
(16) \quad u \otimes \delta \otimes \bigotimes_{i \in I - \{0\}} b_i \otimes \bigotimes_{k \in (n)} x_k
\end{equation}

where $c : I \to [0]$, $0 \in I$, $c(0) = c_0$, $\delta \in J_{c_0}$, $u \in \mathcal{O}(c^{*n}, e)$, $b_i \in A_{c(i)}$ and $x_k \in H_a$.

We will now explicitly calculate the image of (16) under the homotopy $\mathbb{F}_O(h) = \sum_{\theta} \mathcal{S}_\theta \circ t_{\theta}$ to make sure it belongs to $J$.

Let

\begin{equation}
t(u) = \sum_{\theta : I \to |I| + n} t_{\theta}(u).
\end{equation}

We claim that $\mathbb{F}_O(h)$ carries (16) to the sum

\begin{equation}
(17) \quad \sum_{\theta} u_{\theta} \otimes \delta \otimes \bigotimes_{i \in I - \{0\}} b_i \otimes \bigotimes_{k \in (n)} x_{\theta,k},
\end{equation}

where

\begin{equation}
x_{\theta,k} = \begin{cases} 
x_k, & k \neq \min_{(n)}(\theta) \\
h(x_k), & k = \min_{(n)}(\theta)
\end{cases}
\end{equation}

It is sufficient to check the formula (17) in case $\delta$ is a monomial in $\mathbb{F}_O(A)$:

\begin{equation}
(19) \quad \delta = m \otimes \bigotimes_{j \in J} a_j
\end{equation}

with $m \in \mathcal{O}(d, c_0)$, $d : J \to [0]$, $a_j \in A_{d(j)}$.

Replace $\delta$ in (16) with the expression (19). We get a monomial

\begin{equation}
(20) \quad z := u \circ m \otimes \bigotimes_{j \in J} a_j \otimes \bigotimes_{i \in I - \{0\}} b_i \otimes \bigotimes_{k \in (n)} x_k,
\end{equation}

where $u \circ m$ denotes the composition of $u$ and $m$ belonging to $\mathcal{O}(c \circ d, e)$ where $c \circ d : I - \{0\} \sqcup J \to [0]$ is the restriction of $c \sqcup d$, whose image under $\mathbb{F}_O(h)$ is given by the formula

\begin{equation}
(21) \quad \mathbb{F}_O(h)(z) = \sum_{\eta : I - \{0\} \sqcup J \rightarrow |I| + |J| - 1} S_\eta \circ t_\eta.
\end{equation}

By the axiom (COM) of $\Sigma$-splitness applied to the surjection $I - \{0\} \sqcup J \rightarrow I$ sending the elements of $J$ to 0 and the elements of $I - \{0\}$ to themselves, we deduce that $\mathbb{F}_O(h)(z)$ is equal to (17).
2.7. Simplicial structure in characteristic zero. All operads are $\Sigma$-split when $k \supset \mathbb{Q}$, so in this case the category of algebras $\text{Alg}_O(C(k))$ has a model structure described in Theorem 2.3.3.

Moreover, polynomial differential forms allow one to define a simplicial structure on the category $\text{Alg}_O(C(k))$ which is (partly) compatible with the model category structure. We will present the definitions and formulate the theorem. The proof is identical to the colorless case described in [H], 4.8.

For $k \supset \mathbb{Q}$ and $n \geq 0$ one defines a dg commutative algebra $\Omega_n$ by the formula

$$\Omega_n = k[x_0, \ldots, x_n, dx_0, \ldots, dx_n]/(\sum x_i - 1, \sum dx_i).$$

The assignment $n \mapsto \Omega_n$ defines a simplicial object in the category of commutative dg algebras over $k$.

For $A, B \in \text{Alg}_O(C(k))$ the simplicial set $\text{Map}(A, B)$ is defined by the formula

$$\text{Map}(A, B)_n = \text{Hom}(A, \Omega_n \otimes B).$$

The compatibility of the simplicial structure on $\text{Alg}_O(C(k))$ with the model category structure is described in the following theorem.

2.7.1. **Theorem.** Assume $k \supset \mathbb{Q}$ and let $O$ be an operad in $C(k)$. The category $\text{Alg}_O(C(k))$ of $O$-algebras with values in $C(k)$ has a structure of model category with quasiisomorphisms as weak equivalences and componentwise surjective maps as fibrations. The category $\text{Alg}_O(C(k))$ has a “weak simplicial model category structure” (see [H.L], 2.4.2), that is a simplicial structure such that the axioms $(\text{M7})$ and the half of the axiom $(\text{M6})$, see [Hir], 9.1.6, are satisfied.

$(\frac{1}{2}\text{M6})$ For every finite simplicial set $K$ and $A \in \text{Alg}_O(C(k))$ the “weak path object” (see [H.L], 2.4.1) $A^K$ exists and is defined by the formula

$$A^K = \Omega(K) \otimes A.$$

$(\text{M7})$ For a cofibration $i : A \to B$ and a fibration $p : X \to Y$ in $\text{Alg}_O(C(k))$ the map of simplicial sets

$$(22) \quad \text{Map}(B, X) \longrightarrow \text{Map}(A, X) \times_{\text{Map}(A, Y)} \text{Map}(B, Y)$$

is a fibration which is trivial if either $i$ or $p$ is trivial.

2.8. The forgetful functor.

2.8.1. **Proposition.** Assume $O$ is homotopically sound. Then the forgetful functor

$$G : \text{Alg}_O(C(k)) \longrightarrow C(k)^{[O]}$$

preserves cofibrations of cofibrant objects.

**Proof.** Since the forgetful functor commutes with the filtered colimits, everything immediately reduces to the cofibrant algebras generated by a finite sequence of
free generators \( x_i, \ i \in I \), where \( I \) is finite and totally ordered, each time with a prescribed value of the differential \( dx_i \).

Let us fix the notation. Let \( c : I \to [0] \) assign a color to each \( x_i \).

The set \( M \) of multi-indices \( m : I \to \mathbb{N} \) is ordered lexicographically: we say that \( m' > m \) iff for some \( i \in I \) one has \( m_i' > m_i \) and \( m_j = m_j' \) for all \( j > i \).

For \( m \in M \) we denote by \( I^m \) the set of pairs \((i,k)\) with \( i \in I \) and \( k \leq m(i) \).

We define \( c_m : I^m \to [0] \) as the composition \( I^m \xrightarrow{\cdot} I \xrightarrow{c} [0] \).

Fix \( a \in [0] \). The component \( A_a \) of the cofibrant \( O \)-algebra generated by \( x_i \), considered as a graded \( k \)-module, is a direct sum indexed by \( M \) of the components

\[
\mathcal{O}(c^m, a) \otimes_{\Sigma_m} \bigotimes_{i \in I} x^{\otimes m_i}_i,
\]

where \( \Sigma_m = \prod_{i \in I} \Sigma_{m_i} \) is the product of symmetric groups acting on \( \mathcal{O}(c^m, a) \) via embedding into the group of automorphisms of \( c^m : I^m \to [0] \). The increasing filtration on \( A_a \) numbered by \( M \) is a filtration by subcomplexes. The associated graded pieces are precisely (23) now considered as complexes. Since \( \mathcal{O} \) is \( \Sigma \)-cofibrant, they are cofibrant complexes of \( k \)-modules. This proves the claim. \( \square \)

3. SM \( \infty \)-categories

In this section we will construct certain SM \( \infty \)-categories (of \( \infty \)-categories, of dg categories and others) by Dwyer-Kan localization. We construct an adjoint pair of functors

\[ \mathcal{C}_{dg} : \text{Cat}^\infty \xrightarrow{\sim} N(\text{dgCat})^\otimes : \mathcal{N}_{dg} \]

between the symmetric monoidal \( \infty \)-categories of infinity-categories and of dg categories, induced by Dold-Kan equivalence. The functor \( \mathcal{C}_{dg} \) is symmetric monoidal, whereas \( \mathcal{N}_{dg} \) is lax symmetric monoidal (that is, a morphism of \( \infty \)-operads).

We will denote \( \text{Cat}^{\infty}_{SM} := \text{Alg}_{\text{com}}(\text{Cat}^\infty) \) and \( \text{dgCat}^{SM} = \text{Alg}_{\text{com}}(N(\text{dgCat})) \).

The functor \( \mathcal{N}_{dg} \) induces a functor

\[ \mathcal{N}_{dg} : \text{dgCat}^{SM} \longrightarrow \text{Cat}^\infty. \]

Furthermore, we will see that both \( \infty \)-categories \( \text{dgCat}^{SM}(k) \) and \( \text{Cat}^\infty \) are enriched over \( \text{Cat}^\infty \), so that \( \mathcal{N}_{dg} \) preserves this enrichment. The latter means that for a pair of symmetric monoidal dg categories \( C, D \) one has a functor

\[ \text{Fun}^\otimes(C, D) \longrightarrow \text{Fun}^\otimes(\mathcal{N}_{dg}(C), \mathcal{N}_{dg}(D)). \]

3.1. Localization. Given a symmetric monoidal \( \infty \)-category \( \mathcal{C}^\otimes \) and a collection of arrows \( W \), we would like to be able to define a SM structure on the localization \( \mathcal{L}(\mathcal{C}, W) \). This is easy if the tensor product preserves \( W \), see [H.L], 4.2. In this case the localization of the total category \( \mathcal{C}^\otimes \) with respect to the collection of
arrows in $\mathcal{C}^\otimes$ generated by $W$, yields what we call a strict SM localization: this is a SM functor

\[
\mathcal{C}^\otimes \longrightarrow \mathcal{L}(\mathcal{C}^\otimes, W^\otimes)
\]

universal among SM functors $\mathcal{C}^\otimes \rightarrow \mathcal{D}^\otimes$ carrying $W$ to equivalences. Moreover, the underlying $\infty$-category of the strict SM localization is the localization $\mathcal{L}(\mathcal{C}, W)$ and the localization functor is also universal among lax monoidal functors $\mathcal{C}^\otimes \rightarrow \mathcal{D}^\otimes$, see [H.L], 4.2.

Strict SM localization seldom exists: tensor product does not always preserves weak equivalences. In this paper we will use the following ad hoc construction. Given a SM $\infty$-category $\mathcal{C}^\otimes$ and a collection of arrows $W$ in $\mathcal{C}$, we will present a full subcategory $\mathcal{C}_0^\otimes$ such that

- The pair $(\mathcal{C}_0^\otimes, W_0 = W \cap \mathcal{C}_0)$ admits a strict SM localization.
- The embedding $\mathcal{C}_0 \longrightarrow \mathcal{C}$ induces an equivalence of the localizations $\mathcal{L}(\mathcal{C}_0, W_0) \rightarrow \mathcal{L}(\mathcal{C}, W)$.

We will call $\mathcal{L}(\mathcal{C}_0^\otimes, W_0^\otimes)$ the SM localization of $(\mathcal{C}^\otimes, W)$. This construction depends, in general, on the choice of $\mathcal{C}_0$. We believe that in the examples below, it satisfies a universal property which makes it right SM localization as defined in [H.L], 4.3. By [H.L], 4.3.3, this is so in Example 3.1.1.

3.1.1. Example: $\text{QC}(k)^\otimes$. Let $k$ be a commutative ring, $\mathcal{C} := C(k)$ the category of complexes of $k$-modules and let $W$ be the collection of quasiisomorphisms. We choose $\mathcal{C}_0$ to be the full subcategory of cofibrant complexes. As a result, we get a SM $\infty$-category denoted as $\text{QC}(k)$. This is the SM $\infty$-category of $k$-modules; its homotopy category is the derived category of $k$.

3.1.2. Example: categories of enriched categories. We will use a similar construction to define SM $\infty$-categories of certain enriched categories. The corresponding model categories were defined by G. Tabuada, see [T1, T2]. These are

- $\text{dgCat}(k)$, the category of categories enriched over $C(k)$.
- $\text{dg}^{\leq 0}\text{Cat}(k)$, that of categories enriched over $C^{\leq 0}(k)$.
- $\text{sMod-Cat}(k)$, that of categories enriched over the simplicial $k$-modules.

Symmetric monoidal structure on all these categories is induced by the symmetric monoidal structure on $C(k)$, $C^{\leq 0}(k)$ and $\text{sMod}(k)$ respectively. In each one of the cases $\mathcal{C} := \text{dgCat}$, $\text{dg}^{\leq 0}\text{Cat}$ or $\text{sMod-Cat}$, the full subcategory $\mathcal{C}_0$ is spanned by the categories whose $\mathcal{K}om$-objects are cofibrant.

In all three cases tensor product preserves weak equivalence of categories belonging to $\mathcal{C}_0$. It remains to check that in all three cases the embedding $\mathcal{C}_0 \longrightarrow \mathcal{C}$ induces an equivalence of DK localizations. This is routinely done using Key Lemma 2.3.6 of [H.L].

This yields symmetric monoidal $\infty$-categories which we denote $N(\text{dgCat})^\otimes$, $N(\text{dg}^{\leq 0}\text{Cat})^\otimes$ and $N(\text{sMod-Cat})^\otimes$. 
3.2. **Dold-Kan correspondence.**

3.2.1. **Classical Dold-Kan equivalence.** Here we will fix some notation. The functor of normalized chains

$$C_* : sMod(k) \longrightarrow C^{\leq 0}(k)$$

from simplicial $k$-modules to nonpositively graded complexes of $k$-modules is well-known to be an equivalence, with the inverse functor

$$N_* : C^{\leq 0}(k) \longrightarrow sMod(k)$$

defined by the formula $N_n(X) = \text{Hom}(C_*(\Delta^n), X)$.

The functor $C_*$ is not symmetric monoidal, but it is very close to be one. One has functorial maps

$$\nabla_{X,Y} : C_*(X) \otimes C_*(Y) \longrightarrow C_*(X \otimes Y)$$

(Eilenberg-MacLane, or shuffle, map), and

$$\Delta_{X,Y} : C_*(X \otimes Y) \longrightarrow C_*(X) \otimes C_*(Y)$$

(Alexander-Whitney map) such that

- The functor $C_*$ is lax symmetric monoidal via $\nabla$.
- It is also colax monoidal via $\Delta$ (equivalently, $N_*$ is lax monoidal via $\Delta$).
- Both $\Delta$ and $\nabla$ are homotopy equivalences and $\Delta \circ \nabla = \text{id}$.

3.2.2. **Enriched categories.** Any lax monoidal functor $F : M \longrightarrow N$ induces a functor

$$F : \text{Cat}_M \longrightarrow \text{Cat}_N$$

between the respective enriched categories.

Therefore, one has a pair of functors

$$\tilde{C} : sMod-Cat(k) \rightleftarrows \text{dg}^{\leq 0}\text{Cat}(k) : \tilde{N},$$

where $\tilde{C} = (C_*, \nabla)$ and $\tilde{N} = (N_*, \Delta)$, with a natural isomorphism $\tilde{N} \circ \tilde{C} = \text{id}$. Note that the functors $\tilde{C}, \tilde{N}$ do not form an adjoint pair.

The functor $\tilde{C}$ is lax symmetric monoidal. Developing the ideas of [SS], Tabuada proved in [T2] that the functor $\tilde{C}$ has a left adjoint and this pair defines a Quillen equivalence.

Therefore, an equivalence

$$N(\tilde{C}) : N(sMod-Cat(k)) \longrightarrow N(\text{dg}^{\leq 0}\text{Cat}(k))$$

is induced. Since it is lax SM, it is a symmetric monoidal equivalence. Since $N(\tilde{N})$ is left inverse, it is an inverse symmetric monoidal equivalence.

---

$^5$but not colax symmetric monoidal!
3.2.3. We can now define an adjoint pair

\[ \mathcal{C}_{dg} : \text{Cat}^X_\infty \longleftrightarrow N(dg\text{Cat}(k))^\circ : \mathcal{N}_{dg} \]

as a composition

\[ N(\text{sCat}^X) \longrightarrow N(\text{sMod-Cat}(k))^\circ \longrightarrow N(dg^{\leq 0}\text{Cat}(k))^\circ \longrightarrow N(dg\text{Cat}(k))^\circ. \]

The adjoint pair in the middle is a SM equivalence. In two other adjoint pairs the left adjoint is symmetric monoidal, therefore the right adjoint is a map of operads, see Appendix A.

Thus, \( \mathcal{C}_{dg} \) is symmetric monoidal and \( \mathcal{N}_{dg} \) is a map of operads.

3.2.4. We will now show that the functor \( \mathcal{N}_{dg} \) carries the dg category \( C(k) \) to \( QC(k) \in \text{Cat}_\infty \). Moreover, \( \mathcal{N}_{dg} \) carries the commutative algebra object \( C(k)^\circ \) to \( QC(k)^\circ \).

Let \( C^c_\sharp(k) \) denote the category of cofibrant complexes of \( k \)-modules. It is \( k \)-linear and so is enriched in a “trivial” way over \( C(k) \):

\[ \text{Hom}_\sharp(X,Y) := Z^0(\text{Hom}(X,Y)). \]

The functor \( \mathcal{N}_{dg} \) carries \( C^c_\sharp(k) \) into the category whose Hom object are discrete (as simplicial objects) \( k \)-modules. We identify \( \mathcal{N}_{dg}(C^c_\sharp(k)) \) with \( C^c_\sharp(k) \) for the obvious reason.

The functor \( \mathcal{N}_{dg} \) applied to the map \( C^c_\sharp(k) \to C^c(k) \) yields a map

\[ C^c_\sharp(k) \longrightarrow \mathcal{N}_{dg}(C^c(k)) \]

which carries quasiisomorphisms to equivalences. Therefore, a map

\[ QC(k) \longrightarrow \mathcal{N}_{dg}(C^c(k)) \]

is induced. It is an equivalence by [H.L], 2.4.3.

Let us show that \( \mathcal{N}_{dg} \) also preserves the symmetric monoidal structure of \( C^c(k) \).

The adjoint pair

\[ \mathcal{C}_{dg} : \text{Cat}^X_\infty \longleftrightarrow N(dg\text{Cat}(k))^\circ : \mathcal{N}_{dg} \]

gives rise to an adjoint pair of functors between the \( \infty \)-categories of commutative algebras in respective categories,

\[ \mathcal{C}_{dg} : \text{Cat}^\text{SM}_\infty \longleftrightarrow dg\text{Cat}^\text{SM}(k) : \mathcal{N}_{dg} \]

that is between symmetric monoidal \( \infty \)-categories and (weak) symmetric monoidal dg categories.

We claim that \( \mathcal{N}_{dg} \) carries the symmetric monoidal dg category \( C^c(k)^\circ \) to \( QC(k)^\circ \) as constructed in \([3.1.1]\).
The dg category $C_c^c(k)$ has a symmetric monoidal structure and the map $C_c^c(k) \to C_c^c(k)$ is a symmetric monoidal functor. Therefore, the induced arrow

$$C_c^c(k) \otimes \mathcal{N}_{dg}(C_c^c(k))$$

is also a symmetric monoidal functor. By universality of symmetric monoidal localization we get a symmetric monoidal functor

$$(33) \quad \mathcal{Q}C(k) \otimes \mathcal{N}_{dg}(C_c^c(k) \otimes \mathcal{N}_{dg}(C_c^c(k))$$

Since we already know that the induced functor $\mathcal{Q}C(k) \to \mathcal{N}_{dg}(C_c^c(k))$ is an equivalence, it is an equivalence of symmetric monoidal $\infty$-categories.

3.3. $\mathcal{N}_{dg}$, enriched. We will now show that the $\infty$-categories $\text{Cat}^{\text{SM}}_\infty$ and $\text{dgCat}^{\text{SM}}_k$ are enriched over $\text{Cat}_\infty$ and the functor $\mathcal{N}_{dg}$ defined in (32) preserves this enrichment. More precisely, we will present, for a pair $A, B$ of symmetric monoidal dg categories, a map of $\infty$-categories

$$(34) \quad \text{Fun}^{\otimes}(A, B) \to \text{Fun}^{\otimes}(\mathcal{N}_{dg}(A), \mathcal{N}_{dg}(B))$$

of respective symmetric monoidal functors extending the map of of spaces of morphisms defined by the functor $\mathcal{N}_{dg}$.

We will first explain the construction in the setup of conventional categories, and then will provide the $\infty$-categorical generalization, using the formalism of SM adjunction (see Appendix A).

3.3.1. A general setup (conventional categories). Let

$$(35) \quad \lambda : \mathcal{E} \leftrightarrow \mathcal{D} : \rho$$

be an adjoint pair of functors between symmetric monoidal categories, so that $\lambda$ is symmetric monoidal (and therefore $\rho$ is lax symmetric monoidal). We assume that $\mathcal{D}$ is cotensored over $\mathcal{E}$, which means that there exists a functor $\eta : \mathcal{E}^{\text{op}} \times \mathcal{D} \to \mathcal{D}$, $(X, A) \mapsto A^X$, adjoint to the bifunctor $\mathcal{E} \times \mathcal{D} \to \mathcal{D}$ carrying the pair $(X, A)$ to $\lambda(A) \otimes A$. One can easily see that $\eta$ is lax symmetric monoidal.

Assume now that $\mathcal{E}$ is cartesian. Then any object $X \in \mathcal{E}$ has an obvious coalgebra structure defined by the diagonal. This implies that for any commutative algebra $A$ in $\mathcal{D}$ and any object $X$ in $\mathcal{E}$ the power object $A^X$ has a commutative algebra structure. The multiplication in $A^X$ is given by the composition

$$A^X \otimes A^X \to (A \otimes A)^{X \times X} \to A^{X \times X} \to A^X.$$
between SM categories, satisfying the above properties, one has a natural isomorphism
\begin{equation}
\rho_2(B^X) = \rho_2(B)^X,
\end{equation}
which induces a canonical map
\begin{equation}
\text{Fun}^\otimes(A, B) \longrightarrow \text{Fun}^\otimes(\rho_2(A), \rho_2(B)).
\end{equation}

3.3.2. Construction for SM ∞-categories. The only claim requiring a special attention when extending the above construction to ∞-categories is the structure of lax symmetric monoidal functor on \( \eta : \mathcal{C}^{\text{op}} \times \mathcal{D} \longrightarrow \mathcal{D} \) induced by the adjunction \((\ref{eq:adjunction})\). The functor \( \lambda \) leads to a \( \mathcal{C} \)-left-tensored structure on \( \mathcal{D} \) given by a SM functor
\begin{equation}
\mathcal{C} \times \mathcal{D} \longrightarrow \mathcal{D}
\end{equation}
defined by the formula \((a, x) \mapsto \lambda(a) \otimes x\).

The corresponding functor \( \mathcal{C}^{\text{op}} \times \mathcal{D}^{\text{op}} \times \mathcal{D} \longrightarrow \mathcal{S} \) carrying the triple \((a, x, y)\) to \(\text{Map}(a \otimes x, y)\) is then lax monoidal by \(\text{A.5.1}\). Existence of \( \mathcal{C} \)-cotensor structure on \( \mathcal{D} \) is equivalent to \(\{1, 3\}\)-representability of this functor. Once more, according to \(\text{A.5.1}\), this implies that the functor
\begin{equation}
\eta : \mathcal{C}^{\text{op}} \times \mathcal{D} \longrightarrow \mathcal{D}
\end{equation}
is lax SM, see \(\text{A.5.3}\).

Now, a lax SM functor induces a functor between respective ∞-categories of commutative algebras. A commutative algebra in \( \mathcal{C}^{\text{op}} \times \mathcal{D} \) is a pair \((X, A)\) where \( X \in \mathcal{C} \) and \( A \in \text{Alg}_{\text{Com}}(\mathcal{D}) \). This yields a required functor
\begin{equation}
\eta^{\text{SM}} : \mathcal{C}^{\text{op}} \times \text{Alg}_{\text{Com}}(\mathcal{D}) \longrightarrow \text{Alg}_{\text{Com}}(\mathcal{D}).
\end{equation}

3.3.3. We wish to apply the above construction to \( \mathcal{C} = \mathcal{D}_1 = \text{Cat}_\infty \), \( \mathcal{D}_2 = N(\text{dgCat}(k)) \). The ∞-categories \( \text{Cat}_\infty \) and \( N(\text{dgCat}(k)) \) can be described as ∞-categories underlying combinatorial model categories, see \(\text{L.T}, 2.2.5.1\) and \(\text{T1}, \text{Thm 1.8}\).

Therefore, the corresponding underlying ∞-categories are presentable. The tensor products in these ∞-categories commute with colimits, so by Corollary 3.2.3.5 of \(\text{L.HA}\) the categories of commutative algebras in \( \text{Cat}_\infty \) and \( N(\text{dgCat}(k)) \) are as well presentable. This implies presentability of the inner Hom given by \(\text{40}\).

We now have to make sure that the \( \text{Cat}_\infty \)-enrichment of \( \text{Cat}_\infty^{\text{SM}} \) defined by the above universal construction, coincides with the standard one.
3.3.4. Inner Hom for SM \( \infty \)-categories. In case \( \mathcal{C} = \mathcal{D} \) has products, the functor \( \eta^{\text{SM}} \) defined in (40) can be described much easier: the functor \( \eta \) preserves products in the second variable; therefore, it carries algebras to algebras. Here is an explicit description of \( \eta^{\text{SM}} \) for \( \mathcal{C} = \text{Cat}_\infty \), where commutative algebras in \( \text{Cat}_\infty \) are presented as \( \infty \)-categories cocartesian over \( N\text{Fin}_* \), see [L.HA], Section 2.

Given a simplicial set \( X \) and a SM \( \infty \)-category \( p : B \rightarrow N\text{Fin}_* \), we define a simplicial set \( B^X \) with a map \( q : B^X \rightarrow N\text{Fin}_* \) as follows. The \( n \)-simplices of \( B^X \) over \( \sigma : \Delta^n \rightarrow N\text{Fin}_* \) are the commutative diagrams

\[
\begin{array}{ccc}
\Delta^n \times X & \xrightarrow{\tilde{\sigma}} & B \\
\downarrow \text{pr}_1 & & \downarrow p \\
\Delta^n & \xrightarrow{\sigma} & N\text{Fin}_*
\end{array}
\]

A diagram (41) with \( n = 1 \) represents a cocartesian lifting of \( \sigma \) iff the restriction of \( \tilde{\sigma} \) to each vertex of \( X \) is cocartesian. This implies that \( q \) is a cocartesian fibration; the fiber of \( q \) at \( \langle n \rangle \) is \( B^n \), so \( q : B^X \rightarrow N\text{Fin}_* \) is a SM \( \infty \)-category.

Now the identity

\[
\text{Map}(X, \text{Fun}^\otimes(A, B)) = \text{Map}_{\text{Cat}_\infty^{\text{SM}}}(A, B^X)
\]

can be easily verified, which proves that \( \text{Cat}_\infty \)-valued function space defined by our general construction is the conventional one for \( \mathcal{C} = \text{Cat}_\infty \).

4. Rectification of algebras

4.1. Introduction. Let \( \mathcal{O} \) be a topological operad (that is, a fibrant simplicial operad) with the set of colors \( [\mathcal{O}] \). We denote \( \mathcal{O}^\otimes \) the corresponding \( \infty \)-operad in the sense of Lurie [L.HA] which is defined as follows.

Let \( \text{Fin}_* \) denote the category of finite pointed sets. Its objects are finite pointed sets \( I_* = I \sqcup \{ * \} \) and the maps \( f : I_* \rightarrow J_* \) satisfy \( f(*) = * \).

We will define first of all a simplicial category \( \tilde{\mathcal{O}}^\otimes \) over \( \text{Fin}_* \), and then will put \( \mathcal{O}^\otimes \) to be the (homotopy coherent) nerve of the simplicial category \( \tilde{\mathcal{O}}^\otimes \). Here is the definition of \( \tilde{\mathcal{O}}^\otimes \).

Its objects over \( I_* \in \text{Fin}_* \) are maps \( c : I \rightarrow [\emptyset] \) and the simplicial sets of morphisms over \( f : I_* \rightarrow J_* \) defined by the formula

\[
\text{Map}^f_{\tilde{\mathcal{O}}^\otimes}(c, d) = \prod_{j \in J} \mathcal{O}(c|_{f^{-1}(j)}), d(j)).
\]

For the details see in [L.T], 1.1.5 and [L.HA], 2.1.1.22.
Fix a commutative ring $k$. We are mostly interested in algebras over $\mathcal{O} \otimes$ with values in the SM $\infty$-category $\text{QC}(k)$ of complexes of $k$-modules described in detail in $3.1.1$.

We want to compare the $\infty$-category $\text{Alg}_\mathcal{O}(\text{QC}(k))$ with the category of "strict" $\mathcal{O}$-algebras $\text{Alg}_\mathcal{O}(C(k))$ defined as in Section $2.3$.

Assume now we are given a quasiisomorphism of operads $R \longrightarrow C_*(\mathcal{O}, k)$ with $\mathcal{R}$ homotopically sound.

In this case, as we know, the category $\text{Alg}_\mathcal{R}_\mathcal{O}(C(k))$ admits a model structure with quasiisomorphisms as weak equivalences and surjective maps as fibrations.

Applying the nerve construction (see $[H.L]$, 2.3) to $\text{Alg}_\mathcal{R}_\mathcal{O}(C(k))$, we get an $\infty$-category. A certain effort is required in order to be able to interpret a strict $\mathcal{R}$-algebra as an object of $\text{Alg}_\mathcal{R}_\mathcal{O}(\text{QC}(k))$. Unexpectedly, the problem exists even if $\mathcal{R} = C_*(\mathcal{O})$. The reason is that the singular chains functor $C_* : s\text{Set} \longrightarrow C(k)$ is not symmetric monoidal.

The construction of the functor $\text{Alg}_\mathcal{R}(C(k)) \longrightarrow \text{Alg}_\mathcal{O}(\text{QC}(k))$ is explained in Subsection $4.2$ below. Once we have this functor, the universal property of the $\infty$-localization yields an $\infty$-functor

$$\Phi : N(\text{Alg}_\mathcal{R}(C(k))) \longrightarrow \text{Alg}_\mathcal{O}(\text{QC}(k)).$$

Here is the central result of this paper.

4.1.1. **Theorem.** Let $\mathcal{O}$ be a topological operad and let $\mathcal{R} \longrightarrow C_*(\mathcal{O})$ is a homotopically sound replacement. Then the functor $\Phi$ is an equivalence.

4.1.2. The proof follows the idea of the proof of $[L.HA]$ 4.1.4.4 dealing with rectification of associative algebras. An $\infty$-categorical version of Barr-Beck theory $[L.HA]$, 6.2, allows one to present an $\mathcal{O}$-algebra $A$ in $\text{QC}(k)$ as a colimit of its monadic Bar-resolution. The latter consists of free algebras which can be easily lifted to $\text{Alg}_\mathcal{R}(C(k))$. The homotopy colimit of this simplicial object in $\text{Alg}_\mathcal{R}(C(k))$ gives the lifting of $A$. Further details of the proof are given in $4.3$ below.

But first of all we have to define the map $\Phi$ in a greater detail.

4.2. **Construction of $\Phi$.** Let $\mathcal{O}$ be a fibrant simplicial operad and let $\mathcal{R} \longrightarrow C_*(\mathcal{O}, k)$ be a quasiisomorphism of dg operads (bijective on colors) with $\mathcal{R}$ homotopically sound. Let $P_{\mathcal{O}}$ be the simplicial PROP generated by $\mathcal{O}$. Its image under $\mathcal{C}_{dg}$, see formula (32), is presented by the SM dg category $P_{C_{\mathcal{O}}}$ which is the $k$-linear PROP generated by dg operad $C_*(\mathcal{O})$. We will replace $P_{C_{\mathcal{O}}}$ with an equivalent SM dg category $P_{\mathcal{R}}$, the PROP generated by the dg operad $\mathcal{R}$.

Any cofibrant $\mathcal{R}$-algebra $A$ in $C(k)$ gives rise to a symmetric monoidal dg functor

$^6$Note that we have changed the notation in order to distinguish two notions of $\mathcal{O}$-algebra!
such that all $A(x)$, $x \in P_R$, are cofibrant, see \ref{sec:cofibrant}.

This yields, in particular, an arrow in $\text{dgCat}^{\text{SM}}(k)$. Applying to it the functor $N_{d\operatorname{g}}$, and composing with the unit map, we get

$$P_0 \to \mathcal{N}_{d\operatorname{g}}(P_R) \to \mathcal{N}_{d\operatorname{g}}(C(k)) = QC(k)^\circ.$$

The above construction defines a composition

$$\text{Alg}_{d\operatorname{g}}^R(C(k))^c \to \text{Fun}^\circ(P_R, C(k)) \simeq \text{Fun}^\circ(P_{C,\circ}, C(k)) \to \text{Fun}^\circ(\mathcal{N}_{d\operatorname{g}}(P_{C,\circ}), QC(k)^\circ) \to \text{Fun}^\circ(P_0, QC^\circ) = \text{Alg}_O(QC(k)).$$

Thus, we have a functor

$$\phi : \text{Alg}_{d\operatorname{g}}^R(C(k))^c \to \text{Alg}_O(QC(k)).$$

It remains to check that $\phi$ carries weak equivalences of cofibrant $R$-algebras to an equivalence. This is really easy: the functor $\phi$ constructed above commutes with the forgetful functors $G^\circ$ and $G$ in the following diagram

$$\begin{diagram}
\text{Alg}_{d\operatorname{g}}^R(C(k))^c & \to & \text{Alg}_O(QC(k)) \\
G^\circ \downarrow & & \downarrow G \\
(C(k)^c)^{[0]} & \to & QC(k)^{[0]},
\end{diagram}$$

where $\phi^{\text{triv}}$ is defined by localization.

Since weak equivalences in $\text{Alg}_{d\operatorname{g}}^R$ are detected by $G^\circ$ and since the functor $G$ is conservative (see \cite{L.HA}, Lemma 3.2.2.6), the assertion follows.

4.3. Proof of \ref{sec:main_theorem}

4.3.1. Look at the commutative diagram obtained from \eqref{eq:main_diagram} by application of the nerve functor to $G^\circ$.

$$\begin{diagram}
N(\text{Alg}_{d\operatorname{g}}^R(C(k))) & \to & \text{Alg}_O(QC(k)) \\
\downarrow N G^\circ & & \downarrow \phi \\
QC(k)^{[0]} & \to & QC(k)^{[0]},
\end{diagram}$$

The reasoning briefly explained in \ref{sec:nerve} is formalized in Corollary 6.2.2.14 of \cite{L.HA}. It claims that the map $\Phi$ in \eqref{eq:main_diagram} is an equivalence, provided the following properties are verified.
1. The functor $G$ is conservative.
2. The functor $\text{NG}^{st}$ is conservative.
3. $G$-split simplicial object in $\text{Alg}_{\mathbb{R}}(\mathcal{QC}(k))$ has a colimit and $G$ preserves this colimit.
4. The unit map $X \to \text{NG}^{st}F^{st}(X) = G\Phi(F^{st}(X))$ induces an equivalence $F(X) \xrightarrow{\sim} \Phi(F^{st}(X))$.

Let us check the assertions 1–4.
The properties 1, 2, 3 is are proven in [L.HA], see 3.2.2.6, 3.1.3.5 and 3.2.3.1.

The functor $F^{st}$ is obtained by application of the nerve construction (see Proposition 2.5.1, [H.L]) to the functor $F_{\mathbb{R}}$ which is left adjoint to the forgetful functor $G^{st} : \text{Alg}^{st}_{\mathbb{R}}(C(k)) \to C(k)^{[0]}$. This proves 2.

The functor $\text{NG}^{st}$ is conservative as weak equivalences in $\text{Alg}^{st}_{\mathbb{R}}$ are detected by $G^{st}$. Thus, it remains to verify the assertions 3 and 4.

Assertion 3.

According to [H.L], 2.5.2, colimits in an $\infty$-category underlying a combinatorial model category can be calculated via derived colimits in the model category. This is applicable to both $C(k)$ and $\text{Alg}^{st}_{\mathbb{R}}(C(k))$.

A simplicial complex $X \in C(k)^{\Delta^{op}}$ will be called colim-$\Delta^{op}$ adapted if

- The canonical map $\text{L colim} X \to \text{colim} X$ is a quasiisomorphism.
- For all $n \in \Delta^{op}$ the components $X_n \in C(k)$ are cofibrant.

Simplicial objects in $\text{Alg}^{st}_{\mathbb{R}}(C(k))$ are algebras over a certain operad which we will denote $\mathcal{R}^{\Delta^{op}}$. In Lemma 4.3.2 below we check that the operad $\mathcal{R}^{\Delta^{op}}$ is also homotopically sound.

Since the category $\Delta^{op}$ is sifted, the colimit over $\Delta^{op}$ commutes with the forgetful functor $G$.

Therefore, in order to deduce Assertion 3, it remains to prove that the forgetful functor

$$\text{Alg}^{st}_{\mathbb{R}}(C(k))^{\Delta^{op}} \to C(k)^{[\mathcal{R}] \times \Delta^{op}}$$

carries cofibrant simplicial algebras to $[\mathcal{R}]$-collections of colim-adapted simplicial complexes. This is also proven in Lemma 4.3.2 below.

4.3.2. Lemma. Assume $\mathcal{R}$ is a homotopically sound operad. Then

a) $\mathcal{R}^{\Delta^{op}}$ is also homotopically sound.

---

Note that 3.1.3.5 is applicable since tensor product in $\mathcal{QC}(k)$ commutes with colimits along each one of the arguments.
b) the forgetful functor

\[ G : \text{Alg}_{\mathcal{R}^{\Delta^\text{op}}} (C(k)) \longrightarrow C(k)^{[\mathcal{R}]} \times \Delta^\text{op} \]

carries cofibrant algebras to collections of colim-adapted simplicial complexes.

**Proof.** We prove that \( \mathcal{R}^C \) is homotopically sound for any category \( C \). The colors of \( \mathcal{R}^C \) are pairs \((c, m)\) where \( c \) is a color of \( \mathcal{R} \) and \( m \in C \). Let \( A \) be an \( \mathcal{R}^C \) algebra and \( M \) a cofibrant contractible complex. Choose a color \((c, m)\) of \( \mathcal{R} \). We have to prove that the map \( A \to B \) is a weak equivalence, where \( B \) is obtained from \( A \) by freely joining \( M \) at color \((c, m)\). In other words, we have to check that for each \( n \in C \) the map \( A(n) \to B(n) \) is a weak equivalence. Note that \( B(n) \) is freely generated over \( A(n) \) as \( \mathcal{R} \)-algebra by \( \text{Hom}_C(m, n) \times M \) which is also cofibrant and contractible. Therefore, \( \mathcal{R}^C \) is admissible by the criterion 2.3.3.

A collection in \( \mathcal{R}^C \) is given by a pair \((c, m)\) where \( c : I \to [\mathcal{R}] \) is a collection in \( \mathcal{R} \) and a function \( m : I \to \text{Ob}(C) \). The complex \( \mathcal{R}^C((c, m), (d, n)) \) is defined as \( \prod \text{Hom}_C(m_i, n) \times \mathcal{R}(c, d) \). The automorphism group of the collection \((c, m)\) of colors in \( \mathcal{R}^C \) is a subgroup of the automorphism group of the collection \( c \) in \( \mathcal{R} \). Thus, if \( \mathcal{R} \) is \( \Sigma \)-cofibrant, \( \mathcal{R}^C \) is \( \Sigma \)-cofibrant as well. This proves the assertion a).

In order to prove the assertion b), we follow the reasoning of the proof of Proposition 2.8.1.

The claim is easily reduced to cofibrant algebras freely generated by a finite sequence of generators \( x_i, i \in I \), of given color \( c : I \to [\mathcal{R}] \), degree \( d : I \to \mathbb{Z} \) and a function \( n : I \to \text{Ob} \Delta^\text{op} \).

For \( M \in C(k) \) and \( n \in \Delta^\text{op} \) we define \( M^\Delta_n(k) \in C(k)^{\Delta^\text{op}} \) as the simplicial object in \( C(k) \) freely generated by \( M \) sitting at \( n \in \Delta^\text{op} \). This means that

\[ M^\Delta_n(k) = \text{Hom}_{\Delta^\text{op}}(n, k) \times M. \]

Furthermore, we denote as \( x_i \Delta \) the simplicial complex \( (kx_i[-d_i])^\Delta \). Then, applying the formula (23), we conclude that \((a, k)\) component of the cofibrant \( \mathcal{R}^\Delta \)-algebra freely generated by \( x_i \), has an increasing filtration whose associated graded pieces have form

\[ \mathcal{R}(e^m, a) \otimes_{\Sigma_m} \bigotimes_{i \in I} (x_i^C)^{\otimes m_i}, \]

in the notation identical to that of Proposition 2.8.1. It remains to note that the tensor product of colim-adapted simplicial complexes is colim-adapted. In fact, let \( X, Y \) be colim-adapted simplicial objects in \( C(k) \). Then, first of all, the tensor
product $X \otimes Y$ has cofibrant components $X_n \otimes Y_n$. Moreover, the diagram

$$\begin{align*}
\text{L colim}(X \otimes Y) \xrightarrow{i} \text{L colim} X \otimes \text{L colim} Y \\
\text{colim}(X \otimes Y) \xrightarrow{j} \text{colim} X \otimes \text{colim} Y
\end{align*}$$

(49)

is commutative and the maps $i$ and $j$ are isomorphisms since $\Delta^{op}$ is sifted ($i$ is actually the Alexander-Whitney map as $\text{L colim}$ is represented by the geometric realization functor).

4.3.3. To prove assertion 4, we will need a minor generalization of [L.HA], 3.1.3.11, describing free algebras generated by a collection of objects corresponding to different colors.

Let $O^\otimes$ be an $\infty$-operad and $a : I \to [0]$ a collection of objects in $O$. Let $\Theta \subset \text{Fin}_*$ denote the subcategory defined by the inert arrows in $\text{Fin}_*$, so that $\Theta$ is the "trivial $\infty$-operad". We identify $\Theta^I$ with the category whose objects are finite sets over $I$ and whose morphisms are inert partial maps over $I$. There is (essentially unique) extension of the map $a : I \to O$ to a map $\theta : \Theta^I \to O^\otimes$ of $\infty$-operads.

Let $q : C^\otimes \to O^\otimes$ be an $O$-monoidal $\infty$-category. A collection of objects $X = \{X_i \in C_i\}$, $i \in I$ defines (essentially uniquely) a $\Theta^I$-algebra $\bar{X}$ in $C$ such that $q \circ \bar{X} = \theta : \Theta^I \to O^\otimes$. Let $F \in \text{Alg}_O(C)$. The lemma below allows one to check whether a given morphism $\bar{X} \to \theta^*(F)$ exhibits $F$ as free $O$-algebra generated by the collection $\{X_i\}$, $i \in I$.

Denote $\Theta^I_{\text{iso}}$ the maximal subgroupoid of $\Theta^I$. In other words, this is the groupoid of finite sets over $I$. For each $y \in O$ we define a Kan simplicial set $P^I_{y}$ as the full subgroupoid of $\Theta^I_{\text{iso}} \times O^\otimes$ spanned by the objects whose component in $O^\otimes$ is given by an active arrow.

One has a canonical map $h : P^I_{y} \times \Delta^1 \twoheadrightarrow O^\otimes$ defined as follows.

Its restriction $h_0$ to $P^I_{y} \times \{0\}$ is the composition $P^I_{y} \to \Theta^I_{\text{iso}} \to O^\otimes$ whereas the restriction $h_1$ to $P^I_{y} \times \{1\}$ carries everything to $\{y\} \in O$. In general, if $\pi$ is a $k$-simplex of $P^I_{y}$ and $\sigma_i$ is a $k$-simplex of $\Delta^1$ having $i$ times value 1 ($i = 0, \ldots, k+1$), then the image of $(\pi, \sigma_i)$ is defined by the formula

$$h(\pi, \sigma_i) = \begin{cases} 
  d_{k+1} \tau, & i = 0 \\
  s_{k-i+1}d_{k-i+1} \tau, & i > 0
\end{cases}$$

(50)

where $\tau$ is the $k+1$-simplex of $O^\otimes$ defining the projection of $\pi$ to $O^\otimes_{y}$.

Now, the map $q : C^\otimes \to O^\otimes$ being cocartesian fibration, the map $h : P^I_{y} \times \Delta^1 \twoheadrightarrow O^\otimes$ can be lifted to a map $H : P^I_{y} \times \Delta^1 \twoheadrightarrow C^\otimes$ so that the restriction
$H_0$ to $\mathcal{P}_{I,y} \times \{0\}$ is the composition

$$
\mathcal{P}_{I,y} \xrightarrow{x} \Theta_{iso}^I \xrightarrow{\chi} C^\otimes
$$

and such that for each $\pi \in \mathcal{P}_{I,y}$ the arrows $H(\pi, \Delta^1)$ is cocartesian.

This yields a map $H_1 : \mathcal{P}_{I,y} \rightarrow \mathcal{C}_y$.

**Definition.** The colimit of $H_1$ constructed above, if exists, is denoted $\text{Sym}_O(\bar{X})_y$.

Let now, $\bar{X}$ be as above, and let $A$ be a a $O$-algebra in $\mathcal{C}$. A choice of a map of $\Theta^I$-algebras $f : \bar{X} \rightarrow \theta^*(A)$, which is given essentially by a collection of maps $f_i : X_i \rightarrow A(i)$, $i \in I$, defines a canonical collection of maps

$$
F_y : \text{Sym}_O(\bar{X})_y \rightarrow A_y
$$

as follows. The map $f : \bar{X} \rightarrow \theta^*(A)$ induces a map

$$
H_0 : A \circ h_0 : \mathcal{P}_{I,y} \rightarrow C^\otimes.
$$

By construction of $\text{Sym}_O(\bar{X})_y$, one obtains a canonical map

$$
H : A \circ h : \mathcal{P}_{I,y} \times \Delta^1 \rightarrow C^\otimes
$$

whose restriction to $\mathcal{P}_{I,y} \times \{1\}$ yields a map $F_y : \text{Sym}_O(\bar{X})_y \rightarrow A_y$.

The following lemma is a straightforward generalization of [L.HA], 3.1.3.11.

**4.3.4. Lemma.** A collection of maps $f_i : X_i \rightarrow \theta^*(A)_i$, $i \in I$, exhibits $A$ as a free algebra generated by $X$ iff for all $y \in O$ the natural map

$$
F_y : \text{Sym}_O(\bar{X})_y \rightarrow A_y
$$

is an equivalence.

□

We will now apply the above lemma to prove Assertion 4. In our context $O^\otimes$ is the $\infty$-operad constructed from a topological operad $O$. We put $I = \{0\}$ and we represent the collection of $X_i \in \mathcal{QC}(k)$ by their cofibrant representatives $Y_i$. Let $\mathbb{F}_\mathcal{R}(Y)$ be the free $\mathcal{R}$-algebra on $Y = \{Y_i\}_{i \in \{0\}}$. We denote $\mathbb{F}$ to be the $O$-algebra in $\mathcal{QC}(k)$ corresponding to $\mathbb{F}_\mathcal{R}(Y)$ as explained in [4.2]. We have canonical maps $Y_i \rightarrow \theta^*(\mathbb{F})_i$, so we can apply the above lemma.

It remains to check that the maps $F_y : \text{Sym}_O(\bar{X})_y \rightarrow \mathbb{F}_y$ are equivalences.

Recall that $\Theta_{iso}^I$ identifies with the groupoid of collections $\text{Fin}/[0]$ used in the description of the (classical) free algebra, see [2.2.5]. One has a canonical projection $\mathcal{P}_{I,y} \rightarrow \mathcal{N} \mathcal{F}\text{in}/[0]$ and $n$-simplices of $\mathcal{P}_{I,y}$ over $\sigma : c_0 \rightarrow \ldots \rightarrow c_n$ in $\mathcal{N} \mathcal{F}\text{in}/[0]$ correspond to $n$-simplices of $\mathcal{O}(c_0, y)$.

The map $\text{Sym}_O(\bar{X})_y \rightarrow \mathbb{F}_y$ is constructed as follows. The map $H_1 : \mathcal{P}_{I,y} \rightarrow \mathcal{QC}$ is the composition

$$
\mathcal{P}_{I,y} \rightarrow \mathcal{N} \mathcal{F}\text{in}/[0] \rightarrow \mathcal{QC},
$$

where the second arrow carries a collection $c : J \rightarrow [0]$ to $\otimes_{j \in J} Y_{c(j)}$. 

The canonical maps $Y_i \xrightarrow{\theta^*} \mathbb{F}_i$ allow one to extend $H_1$ to a functor
$$H_1^\circ : \mathcal{P}_I \xrightarrow{} \mathcal{QC}$$
carrying the vertex on the left to $\mathbb{F}_y = \text{colim} \mathcal{F}(Y)_y$, where the functor $\mathcal{F}(Y)_y : \text{Fin} / [\mathcal{O}] \xrightarrow{} C(k)$ is given by the formula $\mathcal{F}(Y)_y(c) = \mathcal{R}(c, y) \otimes \bigotimes_{j \in J} Y_{c(j)}$, see formula (4).

The extension $H_1^\circ$ is constructed as follows. One chooses a section $s$ of the projection $N_*(\mathcal{R}(c, y)) \xrightarrow{} N_*(\mathcal{O}(c, y)))$. We will denote by the same letter the composition $s : \mathcal{O}(c, y) \xrightarrow{} N_*(\mathcal{O}(c, y))) \xrightarrow{} N_*(\mathcal{R}(c, y)))$. Now, given an $n$-simplex $(\sigma, \tau)$ of $\mathcal{P}_I$, where $\sigma : c_0 \to \ldots \to c_n$ in $\text{Fin} / [\mathcal{O}]$ and $\tau \in \mathcal{O}(c_0, y)_n$, one extends it with the map $\mathcal{C}_*(\Delta^n) \xrightarrow{} \mathbb{F}_y$ defined by the map $\mathcal{C}_*(\Delta^n) \xrightarrow{} \mathcal{R}(c_0, y)$ determined by $s(\tau)$. It remains to check that $H_1^\circ : \mathcal{P}_I \xrightarrow{} \mathcal{QC}(k)$ is a colimit diagram.

In fact, since the functor $H_1$ factors through $\text{Fin} / [\mathcal{O}]$, see (52), $\text{colim} H_1$ can be calculated as the colimit of the left Kan extension of $H_1$ via the projection
$$\mathcal{P}_I \xrightarrow{} \text{Fin} / [\mathcal{O}].$$
This functor is a Kan fibration, so by [L.T], 4.3.3.1 the left Kan extension of $H_1$ is precisely the functor $\mathcal{F}(Y)_y$. Since $\mathcal{R}$ is $\Sigma$-cofibrant, its (naive) colimit calculates as well the required homotopy colimit. 

4.4. Algebras over a PROP. Theorem 4.1.1 allows one to get a certain rectification result for algebras over a topological PROP, or, more generally, over any SM topological category.

A topological SM category $\mathcal{P}$ determines a SM $\infty$-category $\mathcal{P}^\otimes$, see 4.1, and the $\infty$-category of algebras $\text{Fun}^\otimes(\mathcal{P}^\otimes, \mathcal{QC}(k)^\otimes)$.

We are going to give a "classical" description of this notion of $\infty$-algebra.

4.4.1. Definition. Let $\mathcal{R}$ be a symmetric monoidal dg category. A homotopy $\mathcal{R}$-algebra in $C(k)$ is a lax SM functor $A : \mathcal{P} \xrightarrow{} C(k)$ such that the natural map
$$A(x) \otimes A(y) \xrightarrow{} A(x \otimes y)$$
duces a quasiisomorphism $A(x) \otimes^L A(y) \xrightarrow{} A(x \otimes y)$ for all $x, y \in \mathcal{P}$.

We denote by $\mathcal{P}^\otimes$ the dg operad defined by $\mathcal{P}$. A lax SM functor $\mathcal{P} \to C(k)$ is just a strict $\mathcal{P}^\otimes$-algebra in $C(k)$.

We need a minor generalization of the above definition. A dg operad $\mathcal{R}$ will be called weak SM category if the corresponding operad enriched over the derived category of $k$ is an (enriched) SM category.

The only example of weak SM category we need is the following.
4.4.2. **Lemma.** Let \( P \) be a SM dg category and let \( R \rightarrow P^o \) be a homotopically sound replacement of dg operads. Then \( R \) is a weak SM category.

If \( R \) is a weak SM category and \( x, y \in [R] \) two objects, tensor product \( x \otimes y \) is defined uniquely up to equivalence. Then Definition 4.4.1 is applicable also for weak SM categories. We will repeat it once more.

4.4.3. **Definition.** Let \( R \) be a weak SM dg category. A homotopy \( R \)-algebra in \( C(k) \) is an algebra over the operad \( R \) such that the natural map

\[
A(x) \otimes A(y) \longrightarrow A(x \otimes y)
\]

induces a quasiisomorphism \( A(x) \otimes^L A(y) \longrightarrow A(x \otimes y) \) for all \( x, y \in [R] \).

Let \( P \) be a topological SM category and let \( R \rightarrow C^*(P, k) \) be a homotopically sound replacement.

The \( \infty \)-category of homotopy \( R \)-algebras is defined as the full subcategory of \( N(Alg_{s\infty}^*(C(k))) \) consisting of homotopy \( R \)-algebras. It can be otherwise described as the DK localization of the category of cofibrant homotopy \( R \)-algebras, with respect to weak equivalences.

Theorem 4.1.1 immediately implies the following result.

4.4.4. **Corollary.** Let \( P \) be a topological SM category, and let \( R \rightarrow C^*(P, k) \) be a homotopically sound replacement of \( C^*(P, k) \) considered as an operad. Let \( P^\otimes \) be the SM \( \infty \)-category defined by \( P \). Then the equivalence of \( \infty \)-categories

\[
\Phi : N(Alg_{s\infty}^*(C(k))) \longrightarrow Alg_{P^\otimes}(QC(k))
\]

induces an equivalence of the subcategory of homotopy \( R \)-algebras with \( Fun^\otimes(P^\otimes, QC(k)^\otimes) \).

\[
\square
\]

5. **Modules**

In this section we deduce from Theorem 4.1.1 the rectification for modules over operad algebras. Our definition of module over an \( O \)-operad algebra is very straightforward. For any \( \infty \)-operad \( O \) we define a new \( \infty \)-operad denoted \( MO \) such that algebras over \( MO \) are pairs \( (A, M) \) where \( A \) is an \( O \)-algebra and \( M \) is an \( A \)-module, see Subsection 5.2.

Theorem 4.1.1 implies the main result of this section Theorem 5.2.3 saying that the \( \infty \)-category of modules over an operad algebra can be described as the infinity category underlying the corresponding model category. The precise formulation is given in [5.2.3]. The proof is based on the result on localization of families of \( \infty \)-categories given in [H.L], Sect. 2.

In his foundational book [L.HA] J. Lurie gives another definition which, under some restrictions, yields for any \( O \)-algebra \( A \) an \( O \)-monoidal category of
A-modules. In Appendix B we show that our definition is equivalent to the one suggested by Lurie, with discarded $\mathcal{O}$-monoidal structure.

5.1. **Classical setting.** Let $\mathcal{O}$ be a topological operad. We define a new topological operad $\mathcal{M}\mathcal{O}$ as follows. We double each color, defining

$$[\mathcal{M}\mathcal{O}] = [\mathcal{O}] \times \{a, m\}.$$ 

A collection of colors in $\mathcal{M}\mathcal{O}$ is given by a pair of maps $\tilde{c} = (c, X_c)$ where $c : I \to [\mathcal{O}]$, $X_c : I \to \{a, m\}$.

The space of operations $\mathcal{M}\mathcal{O}(\tilde{c}, \tilde{d})$ for $\tilde{c} : I \to [\mathcal{M}\mathcal{O}]$, $\tilde{d} \in [\mathcal{M}\mathcal{O}]$ is nonempty in two cases described below.

- $X_c(i) = a$ for all $i \in I$, $X_d = a$.
- $X_c(i) = m$ for precisely one $i \in I$, $X_d = m$.

In these cases $\mathcal{M}\mathcal{O}(\tilde{c}, \tilde{d}) = \mathcal{O}(c, d)$.

Note that the same construction makes sense for operads enriched over any SM category.

One has a map $\mathcal{O} \to \mathcal{M}\mathcal{O}$ carrying any $c \in [\mathcal{O}]$ to $(c, a)$. In the opposite direction, a map $\mathcal{M}\mathcal{O} \to \mathcal{O}$ erases the $X$-marking of a color.

Algebras over $\mathcal{M}\mathcal{O}$ are pairs $(A, M)$ where $A$ is an $\mathcal{O}$-algebra and $M$ is an $A$-module.

5.2. A similar construction makes sense in the context of $\infty$-operads. Given an $\infty$-operad $\mathcal{O}^\otimes$ we define a new operad $\mathcal{M}\mathcal{O}^\otimes$ by the formula

$$\mathcal{M}\mathcal{O}^\otimes = \mathcal{C}\mathcal{M}^\otimes \times_{N_{\text{Fin}^*}} \mathcal{O}^\otimes,$$

where $\mathcal{C}\mathcal{M}$ is the two-color operad governing pairs $(A, M)$ with $A$ a commutative algebra and $M$ an $A$-module, and $\mathcal{C}\mathcal{M}^\otimes$ is the corresponding $\infty$-operad.

5.2.1. **Definition.** Let $\mathcal{O}^\otimes$ be an $\infty$-operad and $\mathcal{C}^\otimes$ a SM $\infty$-category. Let $A \in \text{Alg}_{\mathcal{O}}(\mathcal{C})$. The $\infty$-category $\text{Mod}_{A}^\mathcal{O}(\mathcal{C})$ is defined as the fiber product

$$\text{Mod}_{A}^\mathcal{O}(\mathcal{C}) = \text{Alg}_{\mathcal{M}\mathcal{O}}(\mathcal{C}) \times_{\text{Alg}_{\mathcal{O}}(\mathcal{C})} \{A\}.$$ 

Let $\mathcal{O}$ be a topological operad and let $\mathcal{R} \longrightarrow C_*(\mathcal{O})$ be a homotopically sound replacement.

We are not sure that $\mathcal{M}\mathcal{R}$ is always homotopically sound. The following, however, is very easy.

5.2.2. **Lemma.** Let $\mathcal{R}$ be a $\Sigma$-split operad in $C(k)$. Then $\mathcal{M}\mathcal{R}$ is also $\Sigma$-split. If $\mathcal{R}$ is $\Sigma$-cofibrant, then $\mathcal{M}\mathcal{R}$ is $\Sigma$-cofibrant.

**Proof.** If the collection of maps $t_\theta : \mathcal{R}(c, d) \to \mathcal{R}(c, d)$, $\theta : I \to \langle |I| \rangle$, provides a $\Sigma$-splitting for $\mathcal{R}$, the same maps provide a $\Sigma$-splitting for nonzero components of $\mathcal{M}\mathcal{R}$ in the notation of [5.1] and [2.5]. The second claim is also obvious. □
In any case, we can choose a homotopically sound replacement

\( \mathcal{M} \longrightarrow C_*(\mathcal{O}) \)

and define \( \mathcal{R} \) as the full suboperad spanned by the original colors of \( \mathcal{O} \). Then by 2.3.3 \( \mathcal{R} \) is a homotopically sound replacement of \( C_*(\mathcal{O}) \).

5.2.3. **Theorem.** Let \( \mathcal{O} \) be a topological operad. Let \( \mathcal{M} \) be a homotopically sound replacement of \( C_*(\mathcal{M}) \) and let \( \mathcal{R} \) be the full suboperad of \( \mathcal{M} \) spanned by the original colors of \( \mathcal{O} \). Let \( A \) be an \( \mathcal{R} \)-algebra in \( C(k) \). There is a canonical equivalence

\[
N(\text{Mod}_A^R(C(k))) \rightarrow \text{Mod}_A^C(QC(k)),
\]

where we denote by the same letter \( A \) the corresponding \( \mathcal{O} \)-algebra in \( QC(k) \).

**Proof.** According to Theorem [4.1.1] one has a commutative diagram of \( \infty \)-categories whose horizontal maps are equivalences.

\[
\begin{array}{ccc}
N(\text{Alg}^R_M(C(k))) & \longrightarrow & \text{Alg}^R_M(QC(k)) \\
\downarrow \phi^st & & \downarrow \phi \\
N(\text{Alg}^st_M(C(k))) & \longrightarrow & \text{Alg}^st_M(QC(k))
\end{array}
\]

This yields an equivalence of the homotopy fibers of the vertical maps. It remains to identify the map of homotopy fibers with the map (53).

The forgetful functor

\[
\text{Alg}^st_M(C(k)) \longrightarrow \text{Alg}^st_R(C(k))
\]

inducing the left vertical arrow \( \phi^st \), preserves cofibrant algebras. This map, restricted to the subcategories spanned by the cofibrant objects, and considered as marked \( \infty \)-categories (quasiisomorphisms being the marked arrows), is a marked cocartesian fibration in the sense of Definition 2.1.1, [H.L]: this is a cocartesian fibration of categories (a map \( f : A \rightarrow A' \) of algebras gives rise to base change map \( f^* : \text{Mod}_A \rightarrow \text{Mod}_{A'} \)), the base change preserves quasiisomorphisms of cofibrant modules, and weak equivalence of cofibrant algebras gives rise to equivalence of the corresponding categories of modules). Then, according to Proposition 2.1.3, [H.L], the (homotopy) fibers of \( \phi^st \) identify with the DK localizations of the fiber of the functor

\[
\phi^st : \text{Alg}^st_M(C(k))^c \longrightarrow \text{Alg}^st_R(C(k))^c
\]

at a cofibrant algebra \( A \).

If we had \( \mathcal{M} = \mathcal{M} \mathcal{R} \), the fiber would be precisely the category of cofibrant \( A \)-modules. In general one has to add a few lines.
We will now present a mini-theory, generalizing to algebras over colored operads the notion of enveloping algebra.

Let $\mathcal{R}$ be a full suboperad of an operad $\mathcal{M}$ such that the following “linearity” condition holds.

Let $c : I \to [\mathcal{M}]$ and $d \in [\mathcal{M}]$ satisfy the condition $\mathcal{M}(c, d) \neq 0$. Then either both $d$ and the image of $c$ belong to $[\mathcal{R}]$, or $d \not\in [\mathcal{R}]$ and there is precisely one $i \in I$ such that $c(i) \not\in [\mathcal{R}]$.

Given a pair of operads $\mathcal{M} \supseteq \mathcal{R}$ satisfying the linearity condition, and an $\mathcal{R}$-algebra $A$ in $C(k)$, we can look at the fiber of the functor $\text{Alg}_{\mathcal{M}}(C(k)) \to \text{Alg}_{\mathcal{R}}(C(k))$ at $A$ as the category of generalized $A$-modules. In case $\mathcal{M} = \mathcal{M}_{\mathcal{R}}$ this fiber is the category of $A$-modules. Keeping in mind this analogy, we will denote it $\text{Mod}^M_A$.

The category $\text{Mod}^M_A$ can be easily described as the category of representations (that is, $C(k)$-enriched functors to $C(k)$) of a category enriched over $C(k)$ which we will call the enveloping category of $A$ and will denote $U^M_\mathcal{R}(A)$. Its objects are the elements of $[\mathcal{M}] - [\mathcal{R}]$. The complex of maps from $x$ to $y$, $x, y \in [\mathcal{M}] - [\mathcal{R}]$, is a certain colimit of tensor products of $\mathcal{M}(c, d)$ along a category of marked trees.

In case $\mathcal{R}$ is a colorless operad and $\mathcal{M} = \mathcal{M}_{\mathcal{R}}$, we recover the classical notion of universal enveloping algebra. In case $\mathcal{R}$ is a full suboperad of two operads $\mathcal{M}$ and $\mathcal{M}'$, a map of operads $f : \mathcal{M} \to \mathcal{M}'$ is said to be over $\mathcal{R}$ if $f|_{\mathcal{R}} = \text{id}$. If $A$ is a cofibrant $\mathcal{R}$-algebra and $f : \mathcal{M} \to \mathcal{M}'$ is a quasiisomorphism of operads over $\mathcal{R}$, the induced map

$$U^M_\mathcal{R}(A) \longrightarrow U^{M'}_\mathcal{R}(A)$$

is an equivalence of dg categories. This can be checked precisely as in the colorless case, see [H], 5.3.3.

We can now complete our proof applying the above claim to $\mathcal{R}$, $\mathcal{M}$ as in the theorem and $\mathcal{M}' = \mathcal{M}_{\mathcal{R}}$. \qed

**Appendix A. Symmetric monoidal adjunction**

Let $F : C \rightleftarrows D : G$ be an adjoint pair of symmetric monoidal categories, so that $F$ is a symmetric monoidal functor. Then it is easy to see that $G$ is automatically lax symmetric monoidal.

In this subsection we study the above phenomenon and its generalizations in the context of $\infty$-categories.

**A.1. Fibrations in $\text{Cat}_\infty$.** We are going to use the notions of left or cocartesian fibration applied to arrows of $\text{Cat}_\infty$ rather than of $\text{sSet}$ as in [L.T], 2.1 and 2.4. Here are the appropriate definitions.
A map $f : X \to Y$ in $\mathbf{Cat}_\infty$ is called a left fibration if the diagram below defined by $f$

\[
\begin{array}{ccc}
X^{\Delta^1} & \to & Y^{\Delta^1} \\
\downarrow & & \downarrow \\
X^{(0)} & \xrightarrow{f} & Y^{(0)}
\end{array}
\]

is cartesian. Equivalently, this means that a map $f$ is equivalent to one represented by a left fibration in $\mathbf{sSet}$.

Similarly, one defines a cocartesian fibration in $\mathbf{Cat}_\infty$ as a map equivalent to one represented by a cocartesian fibration in $\mathbf{sSet}$. Let $X, Y$ be $\infty$-categories. A map $f : X \to Y$ in $\mathbf{sSet}$ represents a cocartesian fibration in $\mathbf{Cat}_\infty$ if it can be embedded into a homotopy commutative triangle of $\infty$-categories

\[
\begin{array}{ccc}
X & \xrightarrow{h} & Z \\
\downarrow & & \downarrow \\
Y & \xleftarrow{g} & Z
\end{array}
\]

where $g$ is a cocartesian fibration in $\mathbf{sSet}$ and $h$ is an equivalence of $\infty$-categories.

Given an $\infty$-category $C$, we denote as $\mathrm{Coc}_C$ the subcategory of $(\mathbf{Cat}_\infty)/C$ spanned by cocartesian fibrations, with arrows preserving the cocartesian liftings. The category $\mathbf{Left}_C$ is the full subcategory of $(\mathbf{Cat}_\infty)/C$ spanned by the left fibrations. One also defines the $\infty$-category $\mathbf{Left}$ as the full subcategory of $\mathrm{Fun}(\Delta^1, \mathbf{Cat}_\infty)$ spanned by the left fibrations. The $\infty$-category $\mathbf{Left}_C$ is the fiber at $C$ of the cartesian fibration $e_1 : \mathrm{Fun}(\Delta^1, C)$ assigning to each arrow in $C$ its target.

A.2. SM Grothendieck construction. Recall that for an $\infty$-category $C$ there is an equivalence

\[
\mathrm{Coc}_C \xrightarrow{\sim} \mathrm{Fun}(C, \mathbf{Cat}_\infty).
\]

In this subsection we will describe symmetric monoidal versions of this correspondence.

A map of SM $\infty$-categories is called SM cocartesian fibration, see [L.HA], 2.1.2.13, if it is presented by a cocartesian fibration of the corresponding $\infty$-categories over $N\mathbf{Fin}_\ast$. In the following proposition $\mathrm{Coc}^{\mathrm{SM}}_{C^\otimes}$ denotes the category of SM cocartesian fibrations over $C^\otimes$.

A.2.1. Proposition. Let $C^\otimes$ be a SM $\infty$-category. There is an equivalence

\[
\mathrm{Coc}^{\mathrm{SM}}_{C^\otimes} \xrightarrow{\sim} \mathrm{Fun}^{\mathrm{lax}}(C^\otimes, \mathbf{Cat}_\infty),
\]
compatible with the equivalence (59).

Proof. Since Cat\(_\infty\) is cartesian closed, the right hand side identifies with the full subcategory of Fun(C\(^\odot\), Cat\(_\infty\)) spanned by the functors F : C\(^\odot\) \to Cat\(_\infty\) which are lax cartesian structures in the sense of [L.HA], 2.4.1.1: any object X = X\(_1\) \oplus \ldots \oplus X\(_n\) with X\(_i\) \in C exhibits F(X) as the product of F(X\(_i\)).

Now the claim follows from the equivalence of two definitions of operad co-cartesian fibration, see [L.HA], 2.1.2.12. □

The following result is an immediate consequence of the above.

A.2.2. Corollary. Let C\(^\odot\) be a SM \(\infty\)-category. There is an equivalence

\[
\text{Left}_{C^\odot}^{\text{SM}} \sim \text{Fun}^{\text{lax}}(C^\odot, S)
\]

between the \(\infty\)-category of left fibrations M\(^\odot\) \to C\(^\odot\) which are SM functors and lax SM functors C\(^\odot\) \to S, compatible with the Grothendieck construction.

The \(\infty\)-category Left\(_{C^\odot}^{\text{SM}}\) has a simple interpretation in terms of Left. The latter \(\infty\)-category has a cartesian SM structure. One has

A.2.3. Lemma. Let C\(^\odot\) be a SM \(\infty\)-category. The obvious functor

\[
\text{Left}_{C^\odot}^{\text{SM}} \to \text{Alg}_{\text{Com}}(\text{Left})
\]

identifies the left-hand side with the fiber of the forgetful functor

\[
\text{Alg}_{\text{Com}}(\text{Left}) \to \text{Cat}^{\text{SM}}_{\infty}
\]

at C\(^\odot\).

Proof. We have to check that if a SM functor f : D\(^\odot\) \to C\(^\odot\) induces a left fibration D \to C of the respective \(\infty\)-categories, then f itself is a left fibration. Applying Proposition 2.4.2.11 of [L.T], we get that f is a locally cocartesian fibration. Moreover, the same proposition gives a description of locally cocartesian arrows: these are arrows \(\alpha : d \to d'\) embeddable into a commutative triangle

\[
d \oslash \alpha \oslash \gamma \oslash d',
\]

where \(\beta\) is \(\pi_D\)-cocartesian for \(\pi : D^\odot \to NFin_*,\) and \(\pi(\gamma) = \text{id}\). Obviously, these are all arrows in D\(^\odot\). Therefore, f is a left fibration. □
A.3. SM pairings. A pairing of ∞-categories is a pair of maps \( C \leftarrow M \rightarrow D \), such that the induced map \( M \rightarrow C \times D \) is a left fibration.\(^8\)

The ∞-category of pairings, \( \text{Pair} \), is defined as the full subcategory of the category \( \text{Fun}(\Lambda^2_0, \text{Cat}_\infty) \), spanned by the diagrams giving rise to a left fibration.

Equivalently, \( \text{Pair} \) can be defined by a cartesian diagram

\[
\begin{array}{ccc}
\text{Pair} & \longrightarrow & \text{Left} \\
\downarrow & & \downarrow \\
\text{Cat}_\infty \times \text{Cat}_\infty & \times & \text{Cat}_\infty \\
\end{array}
\]

A pairing is uniquely defined, up to a usual ambiguity, by a corresponding functor to the category of spaces \( C \times D \rightarrow S \).

The forgetful functor \( \text{Pair} \rightarrow \text{Cat}_\infty \times \text{Cat}_\infty \) induces a functor

\[
\text{Alg}_{\text{Com}}(\text{Pair}) \rightarrow \text{Cat}^{\text{SM}}_\infty \times \text{Cat}^{\text{SM}}_\infty. 
\]

For a pair \((C, D)\) of SM ∞-categories we denote as \( \text{Alg}_{\text{Com}}(\text{Pair})(C, D) \) the fiber of this functor at \((C, D)\).

According to Corollary A.2.2 and Lemma A.2.3, one has an equivalence

\[
\text{Alg}_{\text{Com}}(\text{Pair})(C, D) \sim \text{Fun}^{\text{lax}}(C \times D, S). 
\]

A.4. Representability. A pairing \((p, q) : M \rightarrow C \times D\) is called left-representable if for any \( x \in C \) the fiber \( p^{-1}(x) \) has an initial object.

We define \( \text{Pair}^l \) as the full subcategory of \( \text{Pair} \) spanned by the left-representable pairings.\(^9\)

A left pairing \( p : M \rightarrow C \times D \) corresponds to a functor \( C \times D \rightarrow S \) which can be equivalently converted into a functor \( \tilde{p} : C \rightarrow P(D^{op}) \).\(^10\) Then \( p \) is left representable iff \( \tilde{p} \) factors through Yoneda embedding \( D^{op} \rightarrow P(D^{op}) \). More precisely, one has the following.

A.4.1. Lemma. The equivalence

\[
\text{Pair}^l(C, D) \sim \text{Fun}(C \times D, S) 
\]

identifies the full subcategory \( \text{Pair}^l(C, D) \) on the left with \( \text{Fun}(C, D^{op}) \) on the right.

Proof. We have to verify that the natural map \( \text{Fun}(C, D^{op}) \rightarrow \text{Fun}(C \times D, S) \) is fully faithful. This is the composition of the equivalence

\[
\text{Fun}(C, P(D^{op})) \rightarrow \text{Fun}(C \times D, S) 
\]

Note: Lurie [L.X], 3.1 and 4.2, uses right fibrations instead.

This differs from the category of left-representable pairings considered in [L.X], 4.2.7 where the arrows are required to be left-representable.

Here \( P(X) \) denotes the presheaves on \( X \).
with the map
\[ \text{Fun}(C, D^{\text{op}}) \longrightarrow \text{Fun}(C, P(D^{\text{op}})) \]
which is fully faithful by Yoneda lemma. □

\textbf{Pair} is closed under direct products. Therefore, commutative algebras in \text{Pair} form a full subcategory of \text{Alg}_{\text{Com}}(\text{Pair}).

Our aim is to prove the following SM version of Lemma A.4.1.

A.4.2. \textbf{Proposition.} The equivalence (65)
\[ \text{Alg}_{\text{Com}}(\text{Pair})_{(C,D)} \sim \text{Fun}^{\text{lax}}(C \times D, S) \]
identifies the full subcategory \text{Alg}_{\text{Com}}(\text{Pair})_{(C,D)} on the left with \text{Fun}^{\text{lax}}(C, D^{\text{op}}) on the right.

The proof is given in A.4.3–A.4.4 below.

A.4.3. \textbf{Opposite} \text{S-family.} Given a cocartesian fibration \( p : C \longrightarrow S \) corresponding to \( p' : C \longrightarrow \text{Cat}_{\infty} \), we define a cocartesian fibration \( p' : C \longrightarrow S \) as the one corresponding to the composition of \( p' \) with the functor \( X \mapsto X^{\text{op}} \).

More explicitly, if \( p \) is presented by a cocartesian fibration \( C \longrightarrow S \) in \( \text{sSet} \), the cocartesian fibration \( C \longrightarrow S \) is defined by the formula
\[ (66) \quad \text{Hom}_{S}(T, C) = \text{Hom}^f(T \times_{S} C, S) := \{ f \in \text{Hom}(T \times_{S} C, S) \mid \forall t \in T, \{ t \} \times_{S} C \rightarrow S \text{ is corepresentable } \}. \]
Note that the formula (66) yields immediately
\[ (67) \quad \text{Fun}_{S}(T, C^{\circ}) = \text{Fun}^f(T \times_{S} C, S), \]
where \( \text{Fun}^f(T \times_{S} C, S) \) is defined as
\[ \text{Fun}^f(T \times_{S} C, S)_n = \text{Hom}^f((T \times \Delta^n) \times_{S} C, S). \]
This is a full subcategory of \( \text{Fun}(T \times_{S} C, S) \) consisting of left-representable functors.

A.4.4. \textbf{Proof of A.4.2.} We will apply the formula (67) to \( S := N\text{Fin}_{\ast}, T := C^{\circ}, C := D^{\circ} \). The right-hand side of (67) contains the full subcategory
\[ \text{Fun}^{f,\text{lax}}(C^{\circ} \times_{N\text{Fun}_{\ast}} D^{\circ}, S) \]
spanned by the left-representable lax cartesian structures on \( C^{\circ} \times_{N\text{Fun}_{\ast}} D^{\circ} \) in the sense of L.HA, 2.4.4.1.

We will now check that the corresponding full subcategory of \( \text{Fun}_{N\text{Fin}_{\ast}}(C^{\circ}, D^{\circ}) \) coincides with \( \text{Fun}^{\text{lax}}(C, D^{\circ}) \).

In fact, let \( f : C^{\circ} \times_{N\text{Fin}_{\ast}} D^{\circ} \longrightarrow S \) be lax cartesian and left-representable. Recall that \( f \) is lax cartesian if for \( c = \bigoplus_{i=1}^{n} c_i, d = \bigoplus_{i=1}^{n} d_i \) the natural map
$f(c, d) \longrightarrow \prod f(c_i, d_i)$ defined by the inert maps $\rho^i : \langle n \rangle \rightarrow \langle 1 \rangle$, is an equivalence. In this case left representability can be checked at $\langle 1 \rangle \in NFin_\ast$ only; it will follow automatically for all $\langle n \rangle \in NFin_\ast$.

Left representability of $f$ yields a map $\tilde{f} : C^\otimes \longrightarrow D^{\otimes_\ast}$ over $NFin_\ast$. If $c = \otimes c_i$ and $d = \tilde{f}(c)$, we have immediately $d = \oplus \tilde{f}(c_i)$ which is equivalent to preservation of inert arrows.

This proves Proposition A.4.2.

A.5. **A generalization.** Proposition A.4.2 has an obvious (and important) generalization to multi-variable adjunction.

Let $K$ be a subset of $\{1, \ldots, n\}$.

A functor $F : C_1 \times \ldots \times C_n \longrightarrow S$ will be called $K$-representable if the corresponding functor $F' : \prod_{i \in K} C_i \longrightarrow P(\prod_{i \notin K} C_i^{\text{op}})$ factors through the fully faithful embedding

$$\prod_{i \notin K} C_i^{\text{op}} \longrightarrow P(\prod_{i \notin K} C_i^{\text{op}}).$$

Let now $C_i$ be symmetric monoidal. The claim below directly follows from Proposition A.4.2.

A.5.1. **Corollary.** There is an equivalence between the following $\infty$-categories.

1. $\text{Fun}^{\text{lax}}(\prod_{i \in K} C_i, \prod_{i \notin K} C_i^{\text{op}})$,
2. The full subcategory of $\text{Fun}^{\text{lax}}(\prod_{i=1}^n C_i, S)$ spanned by the lax functors which are $K$-representable, once the SM structure is discarded.

A.5.2. **Example.** In particular, if a SM functor $f : C \longrightarrow D$ admits a right adjoint as a functor between $\infty$-categories, its right adjoint has a canonical lax SM structure, see also [H.L], 3.1.1.

A.5.3. **Example.** A symmetric monoidal functor $f : C \longrightarrow D$ determines on $D$ a $C$-tensored structure, defined by a functor

$$C \times D \longrightarrow D, \quad (x, y) \mapsto f(x) \otimes y$$

which is also symmetric monoidal. This implies that, if $f$ induces also a $C$-cotensored structure on $D$

$$C^{\text{op}} \times D \longrightarrow D,$$

it is automatically lax symmetric monoidal.

**Appendix B. Comparison of two notions of module**

B.1. In this appendix we assume that the operad $O^{\otimes}$ is unital (see [L.HA], 2.3.1), that is that the space $\text{Map}(\emptyset, x)$ is contractible for any $x \in O$. Here $\emptyset$ belongs to the contractible space $O^{\otimes}_{(0)}$. 

Denote $S_0$ the full subcategory of $\text{Fun}(\Delta^1, \mathcal{O}^\otimes)$ spanned by the semi-inert arrows (see [L.HA], 3.3.1) $x \to y$ in $\mathcal{O}^\otimes$ with $p(x) = \langle 1 \rangle \in \text{Fin}_*$.

The maps $s, t: S_0 \longrightarrow \mathcal{O}^\otimes$ assign to an edge its source and its target, respectively.

**B.1.1. Lemma.** The map $t: S_0 \longrightarrow \mathcal{O}^\otimes$ is a categorical fibration.

*Proof.* The map is the composition $S_0 \to \text{Fun}(\Delta^1, \mathcal{O}^\otimes) \xrightarrow{e_1} \mathcal{O}^\otimes$. The second map is a cartesian fibration by [L.T], 2.4.7.11 and 2.4.7.5. In particular, it is a categorical fibration. The first map is an embedding as a full subcategory, so is an inner fibration. Now Joyal’s criterion [L.T], 2.4.6.5 immediately shows it is also a categorical fibration. □

An edge $\alpha$ in $S_0$ will be called inert if both $s(\alpha)$ and $t(\alpha)$ are inert edges in $\mathcal{O}^\otimes$. Note that $s(\alpha)$ has to be an equivalence since it lives over an inert endomorphism of $\langle 1 \rangle \in \text{Fin}_*$ which has to be identity.

The assignment $\mathcal{O}^\otimes \mapsto S_0$ is functorial. One can identify $S_{\text{Com}}$ with a suboperad of $\mathcal{CM}^\otimes$ via the map

$$\iota: S_{\text{Com}} \longrightarrow \mathcal{CM}^\otimes$$

(68)

carrying an arrow $\alpha: \langle 1 \rangle \to I_*$ to the characteristic function $h: I \to \{a, m\}$ of the image of $\alpha$: $h$ has value $m$ on the image and $a$ otherwise.

The commutative diagram

$$
\begin{array}{ccc}
S_0 & \longrightarrow & S_{\text{Com}} \\
\downarrow & & \downarrow \\
\mathcal{O}^\otimes & \longrightarrow & N\text{Fin}_* \\
\iota & & \pi \\
\downarrow & & \downarrow \\
N\text{Fin}_* & \longrightarrow & N\text{Fin}_*
\end{array}
$$

(69)

defines the maps

$$
S_0 \xrightarrow{\pi} S_{\text{Com}} \times_{N\text{Fin}_*} \mathcal{O}^\otimes \xrightarrow{\iota} \mathcal{CM}^\otimes \times_{N\text{Fin}_*} \mathcal{O}^\otimes.
$$

(70)

The following result shows that Definition 5.2.1 of the category of modules over an $\infty$-operad algebra is equivalent to the one given by Lurie in [L.HA], 3.3.3.8.

In particular, Corollary 5.2.3 is applicable to Lurie modules (with $\mathcal{O}$-monoidal structure discarded).

---

11In the notation of Lurie [L.HA], 3.3.2.1, $S_0$ is the fiber of the composition $p \circ e_0: K_0^\otimes \to \mathcal{O}^\otimes \to N\text{Fin}_*$ at $\langle 1 \rangle$. 
B.1.2. Proposition. Assume that $\mathcal{O}^\otimes$ is unital and $\mathcal{O}$ is Kan (this is so if $\mathcal{O}^\otimes$ is coherent \cite{LurieHA}, 3.3.1.9). Then the maps $\pi$ and $\iota$ in (70) are weak equivalences in $\text{Pop}_\infty$.

The proof of the proposition is given in B.2.1–B.2.7. We will prove that the $\iota$ and $\iota \circ \pi$ are weak equivalences in $\text{Pop}_\infty$.

This will be done using Lurie’s notion of approximation of operads. We check that both $\iota$ and $\iota \circ \pi$ are approximations in the sense of \cite{LurieHA}, 2.3.3.6.

Then, using \cite{LurieHA}, 2.3.3.23(1), we deduce that the maps $\iota$ and $\iota \circ \pi$ are weak equivalences.

B.2. Proof of B.1.2

B.2.1. $\iota$ is an approximation. The map $\iota$ is obtained from the embedding $\iota_{\text{Com}} : \mathcal{S}_{\text{Com}} \to \mathcal{CM}^\otimes$ by a base change along fibration $p : \mathcal{O}^\otimes \to \text{NFin}_\ast$. Therefore, by Remark 2.3.3.9 of \cite{LurieHA}, in order to prove $\iota$ is an approximation, it suffices to check that the map $\iota_{\text{Com}}$ is an approximation. $\mathcal{S}_{\text{Com}}$ is a full subcategory of $\mathcal{CM}^\otimes$ spanned by the objects having at most one appearance of $m$. Thus, if an arrow $\alpha : x \to y$ in $\mathcal{CM}^\otimes$ is inert and $x \in \mathcal{S}_{\text{Com}}$ then $y \in \mathcal{S}_{\text{Com}}$. Similarly, if $\alpha$ is active and $y \in \mathcal{S}_{\text{Com}}$ then $x \in \mathcal{S}_{\text{Com}}$. This implies $\iota_{\text{Com}}$ is an approximation.

We will now prove that $\iota \circ \pi$ is also an approximation. This is done in B.2.2–B.2.6.

B.2.2. $\iota \circ \pi$ is a categorical fibration. Let $A \to B$ be a trivial cofibration of simplicial sets in the Joyal model structure. Given a pair of compatible maps $a : A \to \mathcal{S}_\mathcal{O}$ and $b : B \to \mathcal{CM}^\otimes \times_{\text{NFin}_\ast} \mathcal{O}^\otimes$, we have to find a lifting $c : B \to \mathcal{S}_\mathcal{O}$ making two triangles commutative.

We proceed as follows. Look at the commutative square with vertical arrows $A \to B$ and $\mathcal{S}_\mathcal{O} \to \mathcal{O}^\otimes$, as shown in the diagram.

\[
\begin{array}{ccc}
A & \xrightarrow{c} & \mathcal{S}_\mathcal{O} \\
\downarrow & & \downarrow \iota \circ \pi \\
B & \xleftarrow{\iota \circ \pi} & \mathcal{CM}^\otimes \times_{\text{NFin}_\ast} \mathcal{O}^\otimes & \xrightarrow{\iota} & \mathcal{O}^\otimes
\end{array}
\]

(71)

By Lemma B.1.1 there is a lifting $c : B \to \mathcal{S}_\mathcal{O}$ making two triangles $ABS_\mathcal{O}$ and $BS_\mathcal{O} \mathcal{O}^\otimes$ commutative. We claim $c$ makes also commutative the triangle we need.
In fact, the commutative diagram

\[
\begin{array}{ccc}
A & \rightarrow & \mathbb{CM}^\otimes \\
\downarrow & & \downarrow \\
B & \rightarrow & N\text{Fin}_* \\
\end{array}
\]

has a unique lifting (as $\mathbb{CM}^\otimes$ and $N\text{Fin}_*$ are both nerves of categories, and the functor between them admits lifting of isomorphisms). This implies that the lifting $c$ automatically satisfies the required property.

B.2.3. Property (1) of [L.HA], 2.3.3.6. If $a : x \rightarrow y$ is an object in $S_\otimes$ and $\bar{b} : p(y) \rightarrow z$ is an inert arrow in $\text{Fin}_*$, we can lift $\bar{b}$ to an inert edge $b : y \rightarrow z$ in $\mathcal{O}^\otimes$ (so that $p(b) = \bar{b}$). One has a triangle $x \xrightarrow{a} y \xrightarrow{b} z$ in $\mathcal{O}^\otimes$ that determines an edge in $S_\otimes$. Its image is obviously inert in $\mathbb{CM}^\otimes \times N\text{Fin}_* \mathcal{O}^\otimes$.

B.2.4. Property (2) of [L.HA], 2.3.3.6. Here the assumptions of B.1.2 on $\mathcal{O}^\otimes$ will be used.

Let $a : x \rightarrow y$ be an object of $S_\otimes$ and let $(\alpha, y) \in \mathbb{CM}^\otimes \times N\text{Fin}_* \mathcal{O}^\otimes$ denote the image $\iota \circ \pi(a)$.

An active edge $\beta : (\gamma, z) \rightarrow (\alpha, y)$ in $\mathbb{CM}^\otimes \times N\text{Fin}_* \mathcal{O}^\otimes$ is uniquely determined by an active edge $b : z \rightarrow y$ in $\mathcal{O}^\otimes$, together with an element $\gamma : p(x) \rightarrow p(z)$ in $S_{\text{Com}}$ such that $p(a) = p(b) \circ \gamma$.

We have to find a cartesian lifting for $\beta$, that is a 2-simplex in $\mathcal{O}^\otimes$

\[
\begin{array}{ccc}
z & \rightarrow & \\
\downarrow & & \downarrow \\
x & \rightarrow & y \\
\end{array}
\]

such that $p(c) = \gamma$ and satisfying a certain universal property.

In case $a$ is null, the map $\gamma$ is null and we choose $c$ to be the null map from $x$ to $z$. The required 2-simplex is now essentially unique as $\text{Map}(0, y)$ is contractible.

In case $a$ is not null let $y = \bigoplus y_i$ with $y_i \in \mathcal{O}$, $z = \bigoplus z_i$ with $z_i \in \mathcal{O}^\otimes$, $b = \bigoplus b_i : z_i \rightarrow y_i$. Let, furthermore, $a$ be defined by an equivalence $a_k : x \rightarrow y_k$. Write $z_k = \bigoplus z^j$ where $z^j \in \mathcal{O}$. The map $\gamma : p(x) \rightarrow p(z)$ factors through $\gamma' : p(x) \rightarrow p(z_k)$ which singles out an element $j$ in $p(z_k)$. This allows one to produce an arrow $z^j \rightarrow y_i$ in $\mathcal{O}$ obtained from $b_i : z_i \rightarrow y_i$ by precomposing with units. It should be equivalence as $\mathcal{O}$ is Kan. Choose a two-simplex $x \rightarrow z^j \rightarrow y_k$ with the described above edges $x \rightarrow y_k$ and $z^j \rightarrow y_k$. Adding to it an essentially
41
unique triangle
\[
0 \rightarrow z \oplus z^j \rightarrow 0 \rightarrow y \oplus y_k,
\]
we get a triangle with required properties.\(^{12}\)

We claim that the edge in \(S_0\) defined by the above two-simplex, is a \(\iota \circ \pi\)-cartesian lifting of \(\beta : (\gamma, z) \rightarrow (p(a), y)\).

The map \(f : S_0 \rightarrow CM \otimes_{NFin_*} O^\otimes\) is a categorical fibration, so the criterion 2.4.4.3 of \([L.T]\) can be applied.

We have to check that for any \(d : s \rightarrow w\) in \(S_0\) the following homotopy commutative diagram
\[
\text{Map}_{S_0}(d, c) \rightarrow \text{Map}_{S_0}(d, a)
\]
\[
\downarrow
\]
\[
\text{Map}_{CM \times_{NFin_*} O^\otimes}(f(d), f(c)) \rightarrow \text{Map}_{CM \times_{NFin_*} O^\otimes}(f(d), f(a))
\]
is homotopy cartesian.\(^{13}\)

Since \(S_0\) is a full subcategory of \(Fun(\Delta^1, O^\otimes)\), we can replace \(Map_{S_0}\) in the above diagram with \(Map_{Fun(\Delta^1, O^\otimes)}\). Here the following easy lemma is very convenient.

**Lemma.** Let \(C\) be an \(\infty\)-category and \(D = Fun(\Delta^1, C)\). Let \(a : x \rightarrow y\) and \(a' : x' \rightarrow y'\) be two objects in \(D\). Then one has a homotopy cartesian diagram
\[
\text{Map}_D(a, a') \rightarrow \text{Map}_C(y, y')
\]

\[
\downarrow
\]
\[
\text{Map}_C(x, x') \rightarrow \text{Map}_C(x, y')
\]

**Proof.** The formulation of the lemma is imprecise: the diagram \((75)\) has to be replaced with an explicit commutative diagram of spaces, similarly to the diagram \((74)\). It is described below. By definition, \(\text{Map}_C(x, y')\) is realized as the fiber of the categorical fibration\(^{13}\)
\[
\text{Fun}(\Delta^1, C) \rightarrow \text{Fun}(\partial \Delta^1, C) = C^2
\]
at the point \((x, y')\). Similarly, \(\text{Map}_D(a, a')\) is realized as the fiber of
\[
\text{Fun}(\Delta^1 \times \Delta^1, C) = \text{Fun}(\Delta^1, D) \rightarrow \text{Fun}(\partial \Delta^1, D) = \text{Fun}(\Delta^1, C)^2
\]

\(^{12}\)Of course \(y \oplus y_k = \oplus_{i \neq k} y_i\) and similarly for \(z \oplus z^j\).

\(^{13}\)To make this formulation precise, one has to replace the map spaces with their explicit representatives by Kan simplicial sets, so that the diagram \((74)\) is commutative.

\(^{14}\)See Lurie, [L.T], 4.2.1, this is the realization via ”alternative join”
at the point \((a, a')\).

Furthermore, we replace the space \(\text{Map}_c(y, y')\) with \(\text{Map}'_c(y, y')\) defined as the fiber of the map

\[
\text{Fun}(\Delta^2, \mathcal{C}) \longrightarrow \text{Fun}(\Delta^1, \mathcal{C}) \times \mathcal{C},
\]
induced by \(\partial^2 : \Delta^1 \to \Delta^2\) and \(\partial^0 \partial^1 : \Delta^0 \to \Delta^2\), at the point \((a, y')\). Similarly, we replace \(\text{Map}_c(x, x')\) with \(\text{Map}'_c(x, x')\) defined as the fiber of the map

\[
\text{Fun}(\Delta^2, \mathcal{C}) \longrightarrow \mathcal{C} \times \text{Fun}(\Delta^1, \mathcal{C}),
\]
induced by \(\partial^0 : \Delta^1 \to \Delta^2\) and \(\partial^1 \partial^2 : \Delta^0 \to \Delta^2\), at the point \((x, a')\).

The canonical maps \(\text{Map}'_c(y, y') \to \text{Map}_c(y, y')\) and \(\text{Map}'_c(x, x') \to \text{Map}_c(x, x')\) are trivial Kan fibrations as they can be obtained by base change from the trivial fibration

\[
\text{Fun}(\Delta^2, \mathcal{C}) \longrightarrow \text{Fun}(\Delta^1, \mathcal{C}).
\]

This, in particular, proves that all \(\text{Map}'\)-spaces are Kan.

The commutative square

\[
\begin{array}{ccc}
\text{Map}_D(a, a') & \longrightarrow & \text{Map}'_c(y, y') \\
\downarrow & & \downarrow \\
\text{Map}_c(x, x') & \longrightarrow & \text{Map}_c(x, y')
\end{array}
\]

replacing the diagram \((75)\), is now obtained from the following commutative cube

\[
\begin{array}{ccc}
\text{Fun}(\Delta^1 \times \Delta^1, \mathcal{C}) & \longrightarrow & \text{Fun}(\Delta^2, \mathcal{C}) \\
\downarrow & & \downarrow \\
\text{Fun}(\Delta^2, \mathcal{C}) & \longrightarrow & \text{Fun}(\Delta^1, \mathcal{C}) \\
\downarrow & & \downarrow \\
\text{Fun}(\Delta^1, \mathcal{C})^2 & \longrightarrow & \text{Fun}(\Delta^1, \mathcal{C}) \times \mathcal{C} \\
\text{Fun}(\Delta^1, \mathcal{C}) \times \mathcal{C} & \longrightarrow & \mathcal{C} \times \text{Fun}(\Delta^1, \mathcal{C}) \\
\downarrow & & \downarrow \\
\mathcal{C} \times \text{Fun}(\Delta^1, \mathcal{C}) & \longrightarrow & \mathcal{C}^2
\end{array}
\]

as the fiber along the vertical edges at \((a, a') \in \text{Fun}(\Delta^1, \mathcal{C})^2\) and at its images.
Here the upper face is defined by the presentation of $\Delta^1 \times \Delta^1$ as a union of two 2-simplices glued along an edge. The upper and the lower faces are cartesian and homotopy cartesian. Therefore, the commutative square (77) of the fibers is also homotopy cartesian.

B.2.6. End of the proof of Property (2). Recall that we have to verify that the diagram (74) is homotopy cartesian.

Note that

\[(79) \quad \text{Map}_{\text{CM} \times \mathcal{O}^\otimes \mathcal{O}^\otimes}(f(d), f(c)) = \text{Map}_{\mathcal{O}^\otimes}(w, z) \times \text{Hom}_{\text{Fin}^*}(p(w), p(z)) \text{Hom}_{\mathcal{O}^\otimes}(p(d), p(c)) = \text{Map}_{\mathcal{O}^\otimes}(w, z) \times \text{Hom}_{\text{Fin}^*}(p(s), p(z)) \text{Hom}_{\text{Fin}^*}(p(s), p(x)),\]

and similarly

\[(80) \quad \text{Map}_{\text{CM} \times \mathcal{O}^\otimes \mathcal{O}^\otimes}(f(d), f(a)) = \text{Map}_{\mathcal{O}^\otimes}(w, y) \times \text{Hom}_{\text{Fin}^*}(p(s), p(y)) \text{Hom}_{\text{Fin}^*}(p(s), p(x)).\]

Let us first replace the diagram (74) with a commutative diagram so that the claim become formally meaningful. Similarly to what we did in the proof of Lemma B.2.5, we replace in (74) $\text{Map}_{\mathcal{O}^\otimes}(d, c)$ and

\[\text{Map}_{\text{CM} \times \mathcal{O}^\otimes \mathcal{O}^\otimes}(f(d), f(c)) = \text{Map}_{\mathcal{O}^\otimes}(w, z) \times \text{Hom}_{\text{Fin}^*}(p(w), p(z)) \text{Hom}_{\mathcal{O}^\otimes}(p(d), p(c)) = \text{Map}_{\mathcal{O}^\otimes}(w, y) \times \text{Hom}_{\text{Fin}^*}(p(s), p(y)) \text{Hom}_{\mathcal{O}^\otimes}(p(s), p(x))\]

with homotopy equivalent versions, $\text{Map}'_{\mathcal{O}^\otimes}(d, c)$ and $\text{Map}'_{\mathcal{O}^\otimes}(w, z) \times \text{Hom}_{\text{Fin}^*}(p(s), p(z)) \text{Hom}_{\mathcal{O}^\otimes}(p(s), p(x))$ where $\text{Map}'_{\mathcal{O}^\otimes}(d, c)$ is the fiber of the map

\[(81) \quad \text{Fun}(\Delta^2, \mathcal{S}_\mathcal{O}) \longrightarrow \mathcal{S}_\mathcal{O} \times \text{Fun}(\Delta^1, \mathcal{S}_\mathcal{O})\]

at $(d, \beta : c \to a)$ whereas $\text{Map}'_{\mathcal{O}^\otimes}(w, z)$ is the fiber of

\[(82) \quad \text{Fun}(\Delta^2, \mathcal{O}^\otimes) \longrightarrow \mathcal{O}^\otimes \times \text{Fun}(\Delta^1, \mathcal{O}^\otimes)\]

at $(w, b : z \to y)$. The maps (81) and (82) are both induced by the embedding $\Delta^0 \sqcup \Delta^1 \longrightarrow \Delta^2$ defined by $\partial^1 \partial^2$ and by $\partial^0$. 
The diagram (74) is now replaced with a commutative diagram

\[
\begin{array}{ccc}
\text{Maps}_{S_0}(d, c) & \xrightarrow{\pi_c} & \text{Map}_{O}(w, z) \times_{\text{Hom}_{\text{Fin}^*}(p(s), p(z))} \text{Hom}_{\text{Fin}^*}(p(s), p(x)) \\
\cong & & \cong \\
\text{Map}'_{S_0}(d, c) & \xrightarrow{\pi'_c} & \text{Map}'_{O}(w, z) \times_{\text{Hom}_{\text{Fin}^*}(p(s), p(z))} \text{Hom}_{\text{Fin}^*}(p(s), p(x)) \\
\text{Maps}_{S_0}(d, a) & \xrightarrow{\pi_a} & \text{Map}_{O}(w, y) \times_{\text{Hom}_{\text{Fin}^*}(p(s), p(y))} \text{Hom}_{\text{Fin}^*}(p(s), p(x))
\end{array}
\]

(83)

The upwards arrows are weak equivalences; we will prove that the lower commutative square is homotopy cartesian, considering separately the cases \(a = 0\) and \(a \neq 0\).

In case \(a\) is non-null, the edge \(c\) is also non-null. In this case we will check that the horizontal arrows \(\pi_c\) and \(\pi_a\) of (83) are equivalences. The case \(a = 0 = c\) will be verified separately.

Case \(a \neq 0\).

We will prove that if \(d : s \to w\) and \(a : x \to y\) are in \(S_0\) so that \(a \neq 0\), then the natural map

\[
\pi_a : \text{Map}_{S_0}(d, a) \longrightarrow \text{Map}_{O}(w, y) \times_{\text{Hom}_{\text{Fin}^*}(p(s), p(y))} \text{Hom}_{\text{Fin}^*}(p(s), p(x))
\]

is an equivalence.

The proof goes as follows. We replace \(\text{Maps}_{S_0}\) with \(\text{Map}_{\text{Fun}(\Delta^1, O)}\) and use Lemma B.2.5 to express it as a fiber product. We have to check therefore that the map

\[
\text{Map}'_{O}(w, y) \times_{\text{Map}_{O}(s, y)} \text{Map}'_{O}(s, x) \longrightarrow \text{Map}_{O}(w, y) \times_{\text{Hom}_{\text{Fin}^*}(p(s), p(y))} \text{Hom}_{\text{Fin}^*}(p(s), p(x))
\]

is an equivalence, where the notation for \(\text{Map}'\) is as in Lemma B.2.5.

Since the map

\[
\text{Map}'_{O}(w, y) \longrightarrow \text{Map}_{O}(w, y)
\]

\(\text{rotated by } 90^\circ\) to fit on the page

\(\text{we denote by } 0\) a null map which exists and is essentially unique for any choice of source and target.
is a trivial fibration, it is sufficient to check that the diagram

\[
\begin{array}{ccc}
\text{Map}'_O(s, x) & \longrightarrow & \text{Map}_O(s, y) \\
\downarrow & & \downarrow \\
\text{Hom}_{\text{Fin}^*}(p(s), p(x)) & \longrightarrow & \text{Hom}_{\text{Fin}^*}(p(s), p(y))
\end{array}
\]

(85)

is cartesian if \(a \neq 0\). In other words, we have to check that for any map \(e : p(s) \to p(x)\) (there are two such maps as \(p(s) = p(x) = \langle 1 \rangle\)) the fiber of the left vertical map at \(e\) is equivalent to the fiber of the right vertical map at \(p(a) \circ e\). If \(e = 0\), both fibers are contractible. Otherwise write \(y = \oplus y_i\) with \(y_i \in O\), so that \(a\) is determined by an equivalence \(a_k : x \to y_k\) for some \(k\). Then the fibers are equivalent respectively to \(\text{Map}'_O(s, x)\) and to \(\text{Map}_O(s, y_k)\), that is, equivalent to each other.

\textbf{Case } \(a = 0\).

We will show that the lower commutative square in (83) is equivalent to the following diagram

\[
\begin{array}{ccc}
\text{Map}_O(s, x) \times F_c & \longrightarrow & \text{Hom}_{\text{Fin}^*}(p(s), p(x)) \times F_c \\
\downarrow & & \downarrow \\
\text{Map}_O(s, x) \times F_a & \longrightarrow & \text{Hom}_{\text{Fin}^*}(p(s), p(x)) \times F_a
\end{array}
\]

(86)

for appropriately chosen \(F_c\) and \(F_a\). This will imply the claim.

We proceed as follows.

Define \(\bar{F}_a\) as the fiber of the map \(\text{Map}_O(w, y) \longrightarrow \text{Hom}_{\text{Fin}^*}(p(s), p(y))\) at zero. Then the target of \(\pi_a\) in the diagram (83) identifies with \(\bar{F}_a \times \text{Hom}_{\text{Fin}^*}(p(s), p(x))\).

Similarly, we define \(\bar{F}_c\) as the fiber of the map \(\text{Map}'_O(w, z) \longrightarrow \text{Hom}_{\text{Fin}^*}(p(s), p(z))\) at zero. This will identify the target of \(\pi'_c\) in the diagram (83) with \(\bar{F}_c \times \text{Hom}_{\text{Fin}^*}(p(s), p(x))\).

The projections \(s, t : S_O \to O^\otimes\) yield the maps

\[
\begin{align*}
s_a : \text{Map}_{S_O}(d, a) & \longrightarrow \text{Map}_O(s, x), \\
t_a : \text{Map}_{S_O}(d, a) & \longrightarrow \text{Map}'_O(w, y),
\end{align*}
\]

(87)

where \(\text{Map}'_O(w, y)\) is defined as the fiber of the map

\[
\text{Fun}(\Delta^2, O^\otimes) \longrightarrow \text{Fun}(\Delta^1, O^\otimes) \times O^\otimes
\]

defined by \(\partial^2 : \Delta^1 \to \Delta^2\) and \(\partial^0 \partial^0 : \Delta^0 \to \Delta^2\), at \((d, y)\). The composition

\[
\text{Map}_{S_O}(d, a) \xrightarrow{t_a} \text{Map}'_O(w, y) \longrightarrow \text{Map}_O(s, y)
\]

is zero. We can therefore define \(F_a\) as the fiber of

\[
\begin{align*}
\text{Map}'_O(w, y) & \longrightarrow \text{Map}_O(s, y)
\end{align*}
\]

(88)
at 0 (at the contractible space of null maps), and get a canonical map
\begin{equation}
\text{Map}_{\mathcal{O}_0}(d, a) \longrightarrow \text{Map}_{\mathcal{O}}(s, x) \times F_a.
\end{equation}
One easily sees this is an equivalence. Note that one has a canonical map $F_a \to \bar{F}_a$
which is a trivial Kan fibration.

Similarly, one has a pair of maps
\begin{equation}
s_c : \text{Map}_{\mathcal{O}_0}(d, c) \longrightarrow \text{Map}_{\mathcal{O}}(s, x), \quad t_c : \text{Map}_{\mathcal{O}_0}(d, c) \longrightarrow \text{Map}_{\mathcal{O}_0}(w, z),
\end{equation}
with $\text{Map}_{\mathcal{O}_0}(w, z)$ defined as the fiber of the map
\begin{equation}
\text{Fun}(\Delta^3, \mathcal{O}^\otimes) \longrightarrow \text{Fun}(\Delta^1, \mathcal{O}^\otimes)^2
\end{equation}
given by $\partial^2 \partial^3 : \Delta^1 \to \Delta^3, \quad \partial^0 \partial^0 : \Delta^1 \to \Delta^3,$ at $(d, b)$.
Once more the composition
\begin{equation}
\text{Map}_{\mathcal{O}_0}(d, c) \xrightarrow{t_c} \text{Map}_{\mathcal{O}_0}(w, z) \longrightarrow \text{Map}_{\mathcal{O}_0}(s, z)
\end{equation}
is zero, so we define $F_c$ as the fiber of
\begin{equation}
\text{Map}_{\mathcal{O}_0}(w, z) \longrightarrow \text{Map}_{\mathcal{O}_0}(s, z)
\end{equation}
at 0 and get a canonical map
\begin{equation}
\text{Map}_{\mathcal{O}_0}(d, c) \longrightarrow \text{Map}_{\mathcal{O}}(s, x) \times F_c.
\end{equation}
It is also an equivalence and the map $F_c \to \bar{F}_c$ is a trivial Kan fibration.
We are done.

B.2.7. Having checked that $\iota$ and $\iota \circ \pi$ are approximations, we can now deduce
from Theorem 2.3.3.23(2) of \cite{L.HA} that both $\iota$ and $\iota \circ \pi$ are weak equivalences.
