(Dated: June 26, 2018)

We present a new explicit class of black holes in the Einstein-Weyl theory with any cosmological constant. These spherically symmetric Schwarzschild-Bach-(anti–)de Sitter geometries (Schwa-Bach-(A)dS) form a three-parameter family determined by the black-hole horizon position, the value of Bach invariant on the horizon, and the cosmological constant. Using a conformal to Kundt metric ansatz, the fourth-order field equations simplify to a compact autonomous system. Its solutions are found as power series, enabling us to directly set the Bach parameter and/or cosmological constant equal to zero. To interpret these spacetimes, we analyse the metric functions. In particular, we demonstrate that for a certain range of positive cosmological constant there are both black-hole and cosmological horizons, with a static region between them. The tidal effects on free test particles and basic thermodynamic quantities are also determined.

I. INTRODUCTION

Black holes, regions with very strong gravity from which not even light can escape, are one of the most fascinating theoretical predictions of Einstein’s general relativity [1]. The first exact solution to this theory was almost immediately found by Schwarzschild [2], describing a static spherically symmetric spacetime. However, it took several decades to fully understand its black-hole nature. This initiated the ‘golden age’ of black hole studies, epitomized by the discovery of astrophysically more relevant Kerr rotating solution [3]. Studies of various aspects of these ‘collapsed objects’, such as influence on matter and fields, the no-hair conjecture, thermodynamic properties, or quantum evaporation, followed soon. Moreover, a great observational effort brought the direct evidence of their existence in our universe when Cygnus X-1 source was identified as a black hole. Also, now it seems that supermassive black holes reside in nuclei of almost all galaxies. Mergers of black-hole binaries have been recently detected as the first gravitational wave signals.

Another remarkable interplay between Einstein’s theory and observed astronomical phenomena is a concept of the cosmological constant. The famous Λ-term was introduced by Einstein into his field equations to allow a static cosmological model [4]. However, it was soon demonstrated by de Sitter [5] that the cosmological constant causes even an empty space to expand exponentially fast [6]. Nowadays, this is employed for a phenomenological description of the observed accelerated expansion of our universe caused by ‘dark energy’. The de Sitter solution also captures main features of the inflationary epoch in the very early universe.

Despite all the great successes of Einstein’s gravity theory, it also has its limits, in particular, impossibility to quantize it in the same way as other fundamental interactions, and perhaps some open cosmological issues. Various extensions of general relativity have thus been considered, see [7] for reviews. In these modified theories, the black hole solutions play a prominent role, providing natural test beds for their comparison [11-14].

In this contribution, we present a new explicit class of static spherically symmetric black hole solutions with a cosmological constant in the Einstein-Weyl gravity [15-16]. It generalizes [17] to include higher-order gravity corrections, and [14-18] to admit any cosmological constant. Within this setting, the vacuum Einstein-Hilbert action contains the Ricci scalar $R$, the cosmological constant $\Lambda$, and a contraction of the Weyl tensor $C_{abcd}$, namely

$$S = \int d^4x \sqrt{-g} \left( \gamma (R - 2\Lambda) - \alpha C_{abcd} C^{abcd} \right), \quad (1.1)$$

where $\alpha, \gamma = G^{-1}$ are constants. The field equations read

$$\gamma (R_{ab} - \frac{1}{2} R g_{ab} + \Lambda g_{ab}) = 4\alpha B_{ab},$$

where $B_{ab} \equiv (\nabla^c \nabla^d + \frac{1}{2} R^{cd}) C_{abcd},$ \quad (1.2)

is the traceless, symmetric and conserved Bach tensor ($g^{ab} B_{ab} = 0, B_{ab} = B_{ba}, B_{ab} ;b = 0$). The trace of the field equations implies $R = 4\Lambda$, so that they simplify to

$$R_{ab} - \Lambda g_{ab} = 4k B_{ab}, \quad (1.3)$$

with $k \equiv \alpha G$. For $k = 0$, vacuum Einstein’s equations with a cosmological constant are immediately obtained. Interestingly, solutions with $\Lambda = 0 \Rightarrow R = 0$ are also solutions to general quadratic gravity admitting black holes, see [13, 18, 20].
In Sec. III we introduce a suitable spherically symmetric metric ansatz, yielding the field equations (1.3) as an autonomous system of ODEs, presented in Sec. II together with a classification of its solutions expressed in the form of power series. The general black-hole case is analyzed in Sec. IV and its properties (specific tidal effects, thermodynamic quantities) are discussed in Secs. V and VI.

II. THE GEOMETRY

A spherically symmetric metric is usually written as

$$ds^2 = -h(r)dt^2 + \frac{dr^2}{f(r)} + r^2(d\theta^2 + \sin^2\theta d\phi^2).$$  (2.1)

However, in [18, 20] it was shown that for investigation of such geometries in quadratic gravity, an alternative form is more convenient,

$$ds^2 = \Omega^2(r)\left[d\theta^2 + \sin^2\theta d\phi^2 - 2du dr + \mathcal{H}(r)dr^2\right].$$  (2.2)

This is related to (2.1) via

$$\bar{r} = \Omega(r), \quad t = u - \int \mathcal{H}(r)^{-1}dr,$$  (2.3)

and the metric functions $\Omega, \mathcal{H}$ give $h, f$ using

$$h(\bar{r}) = -\Omega^2 \mathcal{H}, \quad f(\bar{r}) = -\left(\frac{\Omega'}{\Omega}\right)^2 \mathcal{H},$$  (2.4)

(prime denotes the derivative with respect to $r$). The new metric (2.2) is conformal to a simple direct-product Kundt ‘seed’, $ds^2 = \Omega^2 ds^2_{\text{Kundt}}$, which is of the algebraic type D, see [21, 23].

In the metric (2.2), the Killing horizons corresponding to $\partial_u = \partial_t$ are located at specific radii $r_h$ satisfying

$$\mathcal{H}|_{r=r_h} = 0.$$  (2.5)

Of course, via (2.4) this gives $h(\bar{r}_h) = 0 = f(\bar{r}_h).$ There is a time-scaling freedom $t \to \sigma^{-1} t$ of the metric (2.1) implying $h \to \sigma^2 h$, which can be used, e.g., to adjust appropriate value of $h$ at a chosen radius.

To uniquely characterize the geometries (2.2), we need the Weyl and Bach scalar curvature invariants,

$$C^{abcd}C_{abcd} = \frac{1}{3} \Omega^{-4}(\mathcal{H}'' + 2)^2,$$  (2.6)

$$B_{ab}B^{ab} = \frac{1}{72} \Omega^{-8}((B_1)^2 + 2(B_1 + B_2)^2),$$  (2.7)

where two independent Bach components are

$$B_1 = \mathcal{H}''', \quad B_2 = \mathcal{H}''' - \frac{1}{2} \mathcal{H}''^2 + 2.$$  (2.8)

Interestingly, $B_{ab} = 0$ if (and only if) $B_1 B_2 = 0$. Thus we distinguish two geometrically different types of solutions in the Einstein-Weyl gravity defined by $B_{ab} = 0$ and $B_{ab} \neq 0$, respectively.

III. THE FIELD EQUATIONS

Under conformal transformations, the Bach tensor simply scales as $B_{ab} = \Omega^{-2} B_{ab}^{\text{Kundt}}$. Explicit evaluation of the field equations (1.3) for (2.3), using the Bianchi identities, yields two simple ODEs for the metric functions $\Omega(r)$ and $\mathcal{H}(r)$, namely

$$\Omega\mathcal{H}'' - 2\Omega^2 = \frac{1}{3}k B_1 \mathcal{H}^{-1},$$  (3.1)

$$\Omega\mathcal{H}'' + 3\Omega^2 \mathcal{H} + \Omega^2 - \Lambda \Omega^4 = \frac{1}{2}k B_2,$$  (3.2)

see [24] for more details. It is also convenient to express the trace of (1.3), namely $R = 4\Lambda$,

$$\Omega\mathcal{H}'' + \mathcal{H}' + \frac{1}{3}(\mathcal{H}'' + 2)\Omega = \frac{2}{3}\Lambda \Omega^3.$$  (3.3)

In fact, it is the derivative of (3.2) minus $\mathcal{H}'$ times (3.1). The crucial point for further investigations is that Eqs. (3.1), (3.2) do not explicitly depend on $r$. Solutions to such an autonomous system can thus be found as power series in $r$ expanded around any point $r_0$

$$\Omega(r) = \Delta^a \sum_{i=0}^{\infty} a_i \Delta^i, \quad \mathcal{H}(r) = \Delta^p \sum_{i=0}^{\infty} c_i \Delta^i,$$  (3.4)

where $\Delta \equiv r - r_0$, and $n, p \in \mathbb{R}$.

A. Vanishing Bach tensor

For $B_{ab} = 0 = B_2$, we deal with Einstein’s theory, and Eqs. (3.1), (3.2) can be directly integrated. Using the gauge freedom $r \to \lambda r + \nu, u \to \lambda^{-1} u$ of the metric (2.2), this immediately implies

$$\Omega(r) = \bar{r} = -\frac{1}{r}, \quad \mathcal{H}(r) = \frac{\Lambda}{3} - r^2 - 2mr^3.$$  (3.5)

These functions represent the Schwarzschild-(anti-)de Sitter spacetime [17, 21, 22] which, expressed in the form (2.1) using (2.4), reads $f = h = 1 - 2m \bar{r}^{-1} - \frac{1}{2} \Lambda \bar{r}^2$.

It is well known [22] that for $0 < 9\Lambda m^2 < 1$ there are two horizons determined by (2.5), namely the black-hole event horizon at $r_h$ and the cosmological horizon at $r_c > r_h$ (they degenerate to $\bar{r}_h = \bar{r}_c = 3m = 1/\sqrt{\Lambda}$ when $9\Lambda m^2 = 1; \Lambda < 0$ admits only the black hole horizon).

B. Non-vanishing Bach tensor

In a generic case ($B_1, B_2 \neq 0$), the system (3.1), (3.2) becomes non-trivially coupled but its solutions can be found in the form (3.3). Substituting these series into the field equations, the dominant powers of $\Delta$ put specific restrictions on the parameters $[n, p]$ and the possible value of $\Lambda$, see Tab. [I] and [24]. In the next section, we will discuss the most interesting case $[0, 1]$. 
TABLE I. The only admitted parameters \([n, p]\) in (3.4), and the cosmological constant \(\Lambda\), restricted by dominant powers of \(\Delta\) in the field equations (3.1), (3.2), and the trace (3.3).
\[
\begin{array}{ccccccc}
 n & 0 & 1 & -1 & -1 & 0 & 0 \\
 p & 0 & 1 & 0 & 0 & 2 & 2 \\
\Lambda & \text{any} & \text{any} & \text{any} & \text{any} & \text{any} & \text{any} \\
\end{array}
\]
\( < 0 \) \\
\( \geq 2 \) \\
\( \frac{1}{8k} \frac{13n^2 + 4(n+1)}{4} \frac{1}{8k} \)

IV. EXPLICIT BLACK HOLES

In the case \(n = 0, p = 1\), the root of \(\mathcal{H}\) representing the non-degenerate Killing horizon (2.5) is explicitly given by \(r_0 \equiv r_h\). The field equations (3.1), (3.2), with (3.3), then restrict the coefficients in the expansions (3.4) as
\[
a_1 = \frac{1}{3c_0} \left[ 2\Lambda c_0^2 - a_0(1 + c_1) \right], \\
c_2 = \frac{1}{6k c_0} \left[ a_0^2(2 - c_1 - \Lambda c_0^2) + 2k(c_0^2 - 1) \right], \\
a_l = \frac{1}{l^2c_0} \left[ \frac{2l}{2l - 1} \sum_{j=0}^{l-1} a_i a_{j-i} a_{l-j} - \frac{1}{5} a_{l-1} \right. \\
\left. - \sum_{i=1}^{l-1} c_i a_{l-i}(l(l-i) + \frac{1}{5} i(i+1)) \right], \\
c_{l+1} = \frac{3}{k(l+2)(l+1)(l-1)} \times \sum_{i=0}^{l-1} a_i a_{l-i}(l-i)(l-1-3i), \quad \text{for} \quad l \geq 2,
\]
with three free parameters \(a_0, c_0, c_1\).

To identify the Schwarzschild-(anti–)de Sitter spacetime (3.5), first we evaluate the Bach tensor (2.8) on the horizon, yielding
\[
\mathcal{B}_1(r_h) = 0, \quad \mathcal{B}_2(r_h) = -\frac{3}{r_h^2} b,
\]
where \(b \equiv \frac{1}{3}(c_1 - 2 - \Lambda c_0^2)\). Interestingly, by setting \(b = 0\) (i.e. for \(c_1 = 2 - \Lambda c_0^2\)), the Bach tensor vanishes everywhere.

Employing the gauge freedom of (2.2), we may also set
\[
a_0 = -\frac{1}{r_h}, \quad c_0 = r_h - \frac{\Lambda}{r_h}.
\]
The explicit solution (3.4), (4.1) for \(b = 0\) then becomes
\[
\Omega(r) = -\frac{1}{r} - \frac{2}{r_h + \frac{\Lambda}{3} - r^2}, \quad \mathcal{H}(r) = \left( \frac{r^2 - r_h^2}{r_h} \right) \left( \frac{r^2 + r_h^2}{r_h} \right)
\]
which is exactly the Schwarzschild-(anti–)de Sitter black hole (3.5) since \(\frac{1}{3} - r_h^2 = 2m r_h^3\).

In the case \(b \neq 0\), we may now separate the ‘Bach contribution’ in the coefficients (4.1) proportional to \(b\) by introducing \(\alpha_i, \gamma_i\). With the same gauge choice (4.2), we obtain a one-parameter extension of the Schwarzschild-(A)\(dS\) spacetime in the Einstein-Weyl theory,
\[
\Omega(r) = -\frac{1}{r} - \frac{b}{r_h} \sum_{i=1}^{\infty} \alpha_i \left( \frac{r_h - r}{\rho r_h} \right)^i, \\
\mathcal{H}(r) = (r - r_h) \left( \frac{r^2}{r_h} - \frac{\Lambda}{3r_h} \left( r^2 + 2rr_h + r_h^2 \right) \right)
\]
\[+ 3b \rho r_h \sum_{i=1}^{\infty} \gamma_i \left( \frac{r - r_h}{\rho r_h} \right)^i, \]
where
\[
\rho \equiv 1 - \frac{\Lambda}{r_h}, \\
\alpha_1 = 1, \quad \gamma_1 = 1, \quad \gamma_2 = \frac{1}{3} \left[ 4 \left( \frac{1}{r_h} \right) (2 + \frac{1}{2k}) + 3b \right],
\]
and \(\alpha_l, \gamma_l\) are (with \(a_0 \equiv 0\) recursively given by
\[
\alpha_l = \frac{1}{l^2} \left[ -\frac{2\Lambda}{3l_h} \sum_{j=0}^{l-1} \sum_{i=0}^{j} \left( \alpha_{l-j} \rho^j + (\rho^{j-1} - b \alpha_{l-j}) (\alpha_i \rho^{j-i} + \alpha_{j-i} (\rho^i + b a_i)) \right) - \frac{1}{3} \alpha_{l-2} (2 + \rho)(l-1)^2 \right. \\
+ \alpha_{l-1} \left[ \frac{1}{3} (1 + \rho)(l(l-1) + \frac{1}{3} l) \right] - 3 \sum_{i=1}^{l-1} (-1)^i \gamma_i (\rho^{j-i} + b a_{l-i}) (l(l-i) + \frac{1}{5} i(i+1)) \right],
\]
\[
\gamma_{l+1} = \frac{(-1)^l}{k l_h^2 (l+2)(l+1)(l-1)} \sum_{i=0}^{l-1} \left[ \alpha_i \rho^{l-i} + \alpha_{l-i} (\rho^l + b a_i) \right] (l-i)(l-1-3i), \quad \text{for} \quad l \geq 2.
\]
All these solutions form a three-parameter family of spherically symmetric black holes (with static regions).

In particular:

- The parameter \(\Lambda\) is the cosmological constant. It can be set to zero, recovering the results of [18].

- The Bach parameter \(b\) determines the Bach tensor contribution. For \(b = 0\), this Schwa-Bach-(A)\(dS\) black hole (4.4), (4.5) reduces to (4.3).
In terms of these three physical parameters, the scalar invariants (2.6), (2.7) on the horizon are

\[ C_{abcd} C^{abcd}(r_h) = 12 \left( (1 + b) r_h^2 - \frac{1}{2} \Lambda \right)^2, \quad (4.8) \]
\[ B_{ab} B^{ab}(r_h) = \frac{r_h^8}{4k^2} b^2. \quad (4.9) \]

In Fig. 1 convergence of the series in (4.4), (4.5) is examined using the d’Alembert ratio test for two different sets of parameters. It clearly indicates that, with \( n \) growing, the ratio between two subsequent terms approaches a specific constant. The series thus asymptotically behave as geometric series. This enables us to estimate the radius of convergence.

Typical behaviour of the metric function \( \mathcal{H}(r) \) outside the black-hole horizon is plotted in Fig. 2. There is a significant qualitative difference between \( \Lambda < 0 \) and \( \Lambda > 0 \). In both cases, the black-hole horizon separates static \((r > r_h)\) and non-static \((r < r_h)\) regions of the spacetime. However, for \( \Lambda > 0 \) an outer boundary of this static region appears, which corresponds to the cosmological horizon given by the second root of \( \mathcal{H} \) (as in the classic Schwarzschild-de Sitter black hole). This is also demonstrated in Fig. 3 by plotting the function \( f(\bar{r}) \) of the common metric (2.1).

V. SPECIFIC TIDAL EFFECTS

The two independent parts (2.8) of the Bach tensor \( B_1, B_2 \) can be observed via a specific relative motion of free test particles described by the equation of geodesic deviation [25]. For an invariant description, we employ an orthonormal frame associated with initially static observer \((\bar{r} = \bar{\theta} = \bar{\phi} = 0)\) with velocity \( u = \dot{u} \partial_\bar{r} = e_{(0)} \), namely \( e_{(1)} = -\bar{u} (\partial_\bar{r} + \mathcal{H} \partial_\tau) \), \( e_{(2)} = \Omega^{-2} \partial_\theta \), and \( e_{(3)} = (\Omega \sin \theta)^{-1} \partial_\phi \). Projection of the equation of geodesic deviation onto this frame gives

\[ \ddot{Z}^{(1)} = \frac{\Lambda}{3} Z^{(1)} + \frac{1}{6} \frac{\mathcal{H}'' + 2}{\Omega^2} Z^{(1)} - \frac{k}{3} \frac{B_1 + B_2}{\Omega^4} Z^{(1)}, \quad (5.1) \]
\[ \ddot{Z}^{(2)} = \frac{\Lambda}{3} Z^{(2)} - \frac{1}{12} \frac{\mathcal{H}''}{\Omega^2} Z^{(2)} + \frac{k}{6} \frac{B_1}{\Omega^4} Z^{(2)}, \quad (5.2) \]

where \( i = 2, 3 \), \( Z^{(a)}(\bar{r}) \) denotes relative position of two particles, and \( \ddot{Z}^{(a)} = e_{(a)}^\mu \frac{\partial}{\partial \bar{r}} \dot{Z}^\mu \) their mutual acceleration. In (5.1), (5.2) we easily identify classic parts corresponding to the isotropic influence of the cosmological constant \( \Lambda \) and the Newtonian tidal effect caused by the Weyl tensor proportional to the square root of (2.6). Moreover, the Einstein-Weyl theory admits two additional effects encoded in the non-trivial Bach tensor components \( B_1, B_2 \). The first of them affects particles in the transverse directions \( \partial_\theta, \partial_\phi \), see (5.2), while the second one induces their radial acceleration along \( \partial_\tau \) via (5.1). Since \( B_1(r_h) = 0 \), on any horizon there is only the radial effect caused by \( B_2(r_h) \).

\[ \text{FIG. 1. The convergence radius can be estimated from the ratio convergence test for solutions (4.4), (4.5), here given by } r_h = -1, k = 0.5 \text{ with } b = 0.2, \Lambda = -2 \text{ (top) and } b = 0.3, \Lambda = 0.2 \text{ (bottom).} \]

\[ \text{FIG. 2. The function } \mathcal{H}(r) \text{ given by (4.5) for two values of the cosmological constant } \Lambda \text{ (with the same parameters as in Fig. 1). Both plots start on the black-hole horizon } r_h = -1 \text{ and are reliable up to the vertical dashed lines indicating the radii of the convergence. For } \Lambda > 0 \text{ the function } \mathcal{H}(r) \text{ seems to have another root corresponding to the cosmological horizon, while for } \Lambda < 0 \text{ it remains non-vanishing. First 50 (red), 100 (orange), 200 (green), 300 (blue) terms in the expansions are used. The results fully agree with the numerical simulation up to the dashed lines.} \]

\[ \text{FIG. 3. The function } f(\bar{r}) \text{ of standard line element (2.1) corresponding to the solution (4.4), (4.5) via (2.4). The } \Lambda > 0 \text{ case (left) indicates the presence of the cosmological horizon at the boundary of the convergence interval (the dashed line). For } \Lambda < 0 \text{ (right), the series converge in the whole plotted range, indicating a static region everywhere above the black-hole horizon.} \]
VI. THERMODYNAMIC QUANTITIES: HORIZON AREA, TEMPERATURE, ENTROPY

Let us also determine main thermodynamic properties of this explicit family of spherically symmetric Schwarzschild-(A)dS black holes. The horizon is generated by the (rescaled) null Killing vector \( \ell \equiv \sigma \partial_r = \sigma \partial_0 \), and thus is located at \( r = r_h \) where \( \mathcal{H} = 0 \), cf. (\ref{2.3}), (\ref{4.3}). Its area is, using (\ref{2.2}), (\ref{4.4}),

\[
A = 4\pi r_h^{-2} = 4\pi \bar{r}_h^{-2}, \tag{6.1}
\]

while its surface gravity (\( \kappa^2 \equiv -\frac{1}{2} \epsilon_{\mu\nu} \epsilon^{\mu'\nu'} \)) reads

\[
\kappa/\sigma = -\frac{1}{2} \mathcal{H}'(r_h) = -\frac{1}{2} \rho r_h = \frac{1}{2} \bar{r}_h^{-1}(1 - \Lambda \bar{r}_h^2). \tag{6.2}
\]

It is the same expression as in the Schwarzschild-(A)dS case, independent of the Bach parameter \( b \). The black-hole horizon temperature \( T = \frac{\kappa}{2\pi \kappa} \) is thus

\[
T/\sigma = -\frac{1}{4\pi} \rho r_h = \frac{1}{4\pi} \bar{r}_h^{-1}(1 - \Lambda \bar{r}_h^2). \tag{6.3}
\]

This is zero for \( \bar{r}_h = \frac{1}{\sqrt{\Lambda}} \) corresponding to the case of extreme Schwarzschild-de Sitter black hole for which the black-hole and cosmological horizons coincide at \( \bar{r}_h = \bar{r}_c \).

However, in higher-derivative theories, we must apply the generalized definition of entropy \( S = (2\pi/\kappa) \oint Q \), see [20], where the Noether charge 2-form on the horizon is

\[
Q = -\frac{\Omega^2}{16\pi} \left[ 1 + \frac{4}{3} k \Lambda + \frac{4}{9} k \frac{\mathcal{B}_1 + \mathcal{B}_2}{\Omega^4} \right] \sin \theta \, d\theta \wedge d\phi. \tag{6.4}
\]

Evaluating the integral, using (\ref{6.1}), (\ref{6.2}), (\ref{4.9}) we get

\[
S = \frac{1}{4} A \left( 1 + \frac{4}{3} k \Lambda - 4k \bar{r}_h^2 b \right) = \frac{1}{4} A \left( 1 + \frac{4}{3} k \Lambda - 4k \bar{r}_h^2 b \right). \tag{6.5}
\]

For the Schwarzschild black hole (\( b = 0, \Lambda = 0 \)) or in the Einstein theory (\( k = 0 \)), this reduces to standard expression \( S = \frac{1}{4} A \). For \( \Lambda = 0 \), the results of [14, 15] are recovered. For the Schwarzschild-(A)dS black hole (\( b = 0 \)) in the Einstein-Weyl gravity, we obtain \( S = \frac{1}{4} A \left( 1 + \frac{4}{3} k \Lambda \right) \), which agrees with the results of [27]. In critical gravity, defined by \( \Lambda = -\frac{2}{\bar{r}_h^2} < 0 \), the entropy is zero. Our formula (6.5) for entropy generalizes all these expressions to the case of Schwarzschild-Bach-(anti-)de Sitter black holes when the Bach tensor is non-vanishing, parameterized by \( b \neq 0 \). In this case, the entropy is non-zero even in critical gravity. For smaller black holes, the deviations from \( S = \frac{1}{4} A \left( 1 + \frac{4}{3} k \Lambda \right) \) are larger.

By replacing the root \( r_h \) by \( r_c \) in (\ref{4.4}), (\ref{4.5}), the solution is expanded around the cosmological horizon. Its temperature and entropy are thus given by (\ref{6.3}) and (\ref{6.5}), respectively, in which \( \bar{r}_h \) is simply replaced by \( \bar{r}_c \).

VII. ACKNOWLEDGEMENTS

This project has been supported by the Czech Science Foundation Grant No. GACR 17-01625S and the Czech-Austrian MOBILITY grant 8J18AT02 (JP, RS), and the Research Plan RVO: 67985840 (VP, AP). We also thank H. Maeda for reading the manuscript.
