House Dust Mite Induces Expression of Intercellular Adhesion Molecule-1 in EoL-1 Human Eosinophilic Leukemic Cells

The house dust mite (HDM) is considered to be the most common indoor allergen associated with bronchial asthma. In this study, we investigated whether crude extract of the HDM Dermatophagoides farinae could activate human eosinophilic leukemic cells (EoL-1) to induce upregulation of cell-surface adhesion molecules. When EoL-1 cells were incubated with D. farinae extract, expression of intercellular adhesion molecule-1 (ICAM-1) significantly increased on the cell surfaces compared to cells incubated with medium alone. In contrast, surface expression of CD11b and CD49d in EoL-1 cells was not affected by D. farinae extract. In addition, pretreatment of cells with NF-κB inhibitor (MG-132) or JNK inhibitor (SP600125) significantly inhibited ICAM-1 expression promoted by HDM extract. However, neither p38 MAP kinase inhibitor nor MEK inhibitor prevented HDM-induced ICAM-1 expression in EoL-1 cells. These results suggest that crude extract of D. farinae induces ICAM-1 expression in EoL-1 cells through signaling pathways involving both NF-κB and JNK.

Key Words: Pyroglyphidae; EoL-1 Cells; Intercellular Adhesion Molecule-1; NF-KappaB

INTRODUCTION

Eosinophils are major inflammatory effector cells, and blood and tissue eosinophilia is a feature of many allergic disorders, such as bronchial asthma (1). The mechanisms controlling eosinophil-mediated tissue inflammation involve the regulation of chemoattractant-dependent interactions with the vascular endothelium and intercellular or cell-extracellular matrix interactions (2). Such interactions are complex processes largely dependent on the expression of adhesion molecules on the eosinophil cell membrane. It has been demonstrated that intercellular adhesion molecule-1 (ICAM-1) is an important factor in many allergic diseases such as asthma (3). ICAM-1 belongs to the immunoglobulin (Ig) superfamily of cellular adhesion molecules and can bind to lymphocyte function-associated antigen-1 (LFA-1), macrophage antigen-1 (Mac-1), fibrinogen, hyaluronan, and CD43 on leucocytes (4). The upregulation of ICAM-1 expression has been reported in activated eosinophils in response to cytokines such as interleukin-3 (IL-3), IL-5, granulocyte macrophage colony-stimulating factor (GM-CSF), and IL-25 (5, 6). Therefore, enhanced expression of ICAM-1 in activated eosinophils at the site of allergic inflammation may allow cell contact-dependent regulation of immune cells in bronchial asthma.

The house dust mite (HDM) Dermatophagoides is the most common indoor allergen and a major cause of perennial asthma worldwide (7). In vitro studies suggest that HDM allergens directly affect a variety of cell types including bronchial epithelial cells and T cells (8, 9), leading to amplification of allergen-induced bronchial asthma. In addition, it has been reported that extract of HDM D. pteronyssinus can activate eosinophils to generate GM-CSF, TNF-α, and IL-8 by activation of NF-κB (10). The transcription factor NF-κB is a central regulator of the immune system and promotes the transcription of over 150 genes (11). For example, upon stimulation with pro-inflammatory cytokines such as TNFα or IL-1β, IκB kinase is activated to phosphorylate IκB, which is then degraded by the proteasome. Degradation of IκB allows NF-κB to translocate into the nucleus where it can bind to κB sequences in the promoters of NF-κB-dependent genes to upregulate transcription. Recent studies have reported that activation of NF-κB mediates the transcription of ICAM-1, vascular cell adhesion molecule-1 (VCAM-1), and cytokines such as GM-CSF and IL-8 in leukocytes (10, 12). However, no information is available regarding the direct effect of D. farinae extract on the expression of adhesion

815
molecules in human eosinophils.

Human eosinophilic leukemic cells (EoL-1) are a useful in vitro model for studying the functions and regulation of human eosinophils. *D. farinae* has been shown to be a predominant species of HDM in Korea (13). Therefore, in the present study, we investigated the effect of *D. farinae* extract on ICAM-1 expression on the surfaces of EoL-1 cells, and the involvement of NF-κB in the expression of ICAM-1 induced by *D. farinae* extract.

**MATERIALS AND METHODS**

**Human eosinophilic leukemic cell line EoL-1 and culture conditions**

The human eosinophilic leukemic cell line EoL-1 (ECACC 94042252) was maintained in RPMI 1640 medium with 25 mM HEPES (Gibco Laboratories, Grand Island, NY, U.S.A.) supplemented with 10% heat inactivated fetal bovine serum (FBS, Gibco Laboratories) in 5% CO₂ and 95% humidified air at 37°C. Pharmacologic inhibitors used in this study were MG-132 (NF-κB proteasome inhibitor), SB-203580 (p38 MAPK inhibitor), U0126 (MEK 1/2 inhibitor), and SP600125 (JNK inhibitor II), which were purchased from Calbiochem Corp (San Diego, CA, U.S.A.) and Cell Signaling (Beverly, MA, U.S.A.). EoL-1 cells were pretreated with various inhibitors for 1 hr at 37°C before incubation with HDM extract.

**Preparation of whole body extract of HDM *D. farinae***

Live or frozen *D. farinae*, reared at the Department of Parasitology, Yonsei University College of Medicine, were pulverized in liquid nitrogen. The HDM sample was defatted with ethylether and then extracted in 100 mL phosphate-buffered saline (PBS) (137 mM NaCl, 1.8 mM KH₂PO₄, 10 mM Na₂HPO₄, 27 mM KCl, pH 7.4) for 72 hr at 4°C. The supernatant was lyophilized and stored at -20°C. U.S.A.) against distilled water for 48 hr. The dialyzed supernatant was lyophilized and stored at -20°C. The HDM extract (cutoff molecular weight 1 kDa; Spectrum, Houston, TX, U.S.A.) was not detected in the HDM extract by a bicinchoninic acid protein assay kit (Pierce, Rockford, IL, U.S.A.).

**Flow cytometry analysis**

EoL-1 cells (1 × 10⁶/mL) were incubated for 1 hr in 48-well flat-bottom tissue culture plates (Costar, Cambridge, MA, U.S.A.) with or without MG-132, SB203580, U0126 or SP600125 at 37°C in a 5% CO₂ incubator. Following this preincubation, the cells were incubated in the presence or absence of HDM extract (5-200 μg/mL) for 4.5 hr in a 5% CO₂ incubator. TNF-α (20 ng/mL) (R & D systems, Minneapolis, MN, U.S.A.) was used as a positive control. After incubation, the cells were washed with cold PBS containing 1% FBS and then incubated for 30 min at 4°C in dark with FITC-conjugated mouse anti-human ICAM-1 mAb (BD Pharmingen, San Diego, CA, U.S.A.), PE-conjugated mouse anti-human CD49d (BD Pharmingen) or PE-labeled mouse anti-human CD11b mAb (BD Pharmingen). FITC- or PE-conjugated mouse IgG (BD Pharmingen) were used as isotype control antibodies. After washing, the cells were resuspended in 200 μL of PBS buffer for flow cytometric analysis. Flow cytometric analysis for fluorescent intensity of ICAM-1, CD49d or CD11b expression on EoL-1 cells was performed on at least 10,000 cells from each sample with the FACScan instrument (BD Biosciences, San Diego, CA, U.S.A.).

**Statistical analysis**

Data were expressed as the mean ± standard error of the mean (SEM) from three to five independent experiments. Statistical significance between treatment and control groups was assessed by Student’s t-test. A probability value of less than 0.05 was considered significant.

**RESULTS**

**Crude extract of *D. farinae* induces cell-surface expression of ICAM-1 in EoL-1 cells**

To address whether extract of *D. farinae* is capable of inducing surface expression of ICAM-1 in EoL-1 cells, we incubated EoL-1 cells with various concentrations (5-200 μg/mL) of HDM extract for 4.5 hr. As shown in Fig. 1, HDM extract induced ICAM-1 expression in EoL-1 cells in a dose-dependent fashion. At 25, 50, 100, and 200 μg/mL, HDM extract strongly induced ICAM-1 expression (mean ± SEM fluorescent intensity: 195.1 ± 5.8, 221.7 ± 7.4, 241.6 ± 9.3, 255.8 ± 12.2, respectively). TNF-α (20 ng/mL) also significantly increased the fluorescent intensity of ICAM-1 expression on EoL-1 cells (mean ± SEM fluorescent intensity: medium 137.6 ± 6.3; TNF-α treatment 249.9 ± 13.0).

Next, we investigated the effect of HDM extract on the expression of CD11b or CD49d in EoL-1 cells. Treatment of EoL-1 cells with HDM extract (100 μg/mL) for 4.5 hr did not cause a significant increase in CD11b or CD49d expression compared to cells incubated in medium alone (data not shown).
**DISCUSSION**

In the present study, we have demonstrated that crude extract of HDM *D. farinae* activates EoL-1 cells to induce ICAM-1 expression. Untreated EoL-1 cells expressed low levels of ICAM-1, but HDM extract significantly enhanced the cell-surface expression of ICAM-1 in a dose-dependent manner. In addition, inhibition of NF-κB with the proteasome inhibitor MG-132 almost completely prevented the surface expression of ICAM-1 induced by HDM extract, suggesting a critical role of NF-κB in the expression of ICAM-1. This result is in line with previous reports (5, 16) that ICAM-1 expression promoted by cytokines is NF-κB dependent in EoL-1 cells and human eosinophils. Moreover, it has been reported that MAPKs including ERK1/2, p38, and JNK are involved in ICAM-1 expression in human eosinophils and pulmonary epithelial cells (5, 15). In this study, we found that pretreatment of EoL-1 cells with JNK inhibitor SP600125, but not p38 inhibitor SB203580 or MEK1/2 inhibitor U0126, resulted in significant reduction of ICAM-1 expression stimulated by HDM extract. This suggests that only JNK MAPK is associated with ICAM-1 expression by HDM extract. Taken together, our results suggest that *D. farinae* extract induces ICAM-1 expression on EoL-1 cells via signaling pathways of NF-κB and JNK MAPK.

ICAM-1 expression on eosinophils is involved in degranulation and superoxide anion production (17, 18). A local increase of eosinophils expressing ICAM-1 has been found in inflammatory respiratory diseases such as asthma and idiopathic eosinophilic pneumonia (19, 20). Eosinophils in the sputum, but not blood, of symptomatic asthmatics not receiving steroid therapy were found to express ICAM-1 (21). Therefore, our findings suggest that *D. farinae*-induced ICAM-1 expression might contribute to amplification of eosinophil-mediated tissue inflammation in bronchial asthma.

Evidence indicates that several mite allergens are proteolytic enzymes (serine and cysteine proteases) and that the protease
activity of the mite allergens sensitizes immune cells. For example, *D. pteronyssinus* allergen *Der p 1* can induce upregulation of surface expression of ICAM-1 (CD54) on endothelial cells (22) and eosinophils (16). In addition, *Der p 1* stimulates cytokine expression in airway epithelial cells through a protease-activated receptor-2 (PAR-2)-dependent mechanism (23). In contrast, human eosinophils are activated by cysteine protease allergen *Der f 1* in a PAR-2 driven manner (24). Further studies on this issue will be required to unravel the immunopathological mechanisms of *D. farinae*-mediated allergic inflammation in bronchial asthma.

In summary, we report that *D. farinae* extract induces upregulation of the cell surface adhesion molecule ICAM-1 in EoL-1 cells through JNK and NF-κB pathways. Our findings may have clinical implications because the exposure to HDM antigens plays an important role in the regulation of eosinophilic inflammation in patients with bronchial asthma.
