THE INTERACTION OF A GAP WITH A FREE
BOUNDARY IN A TWO DIMENSIONAL DIMER SYSTEM

Abstract. Let $\ell$ be a fixed vertical lattice line of the unit triangular lattice in the plane, and let $\mathcal{H}$ be the half plane to the left of $\ell$. We consider lozenge tilings of $\mathcal{H}$ that have a triangular gap of side-length two and in which $\ell$ is a free boundary — i.e., tiles are allowed to protrude out half-way across $\ell$. We prove that the correlation function of this gap near the free boundary has asymptotics $\frac{1}{4\pi r}$, $r \to \infty$, where $r$ is the distance from the gap to the free boundary. This parallels the electrostatic phenomenon by which the field of an electric charge near a conductor can be obtained by the method of images.

1. Introduction

The study of the interaction of gaps in dimer coverings was introduced in the literature by Fisher and Stephenson [13]. This pioneering work contains three different types of gap interaction in dimer systems on the square lattice: (i) interaction of two dimer-gaps (equivalently, interaction of two fixed dimers required to be contained in the dimer coverings); (ii) interaction of two non-dimer-gaps (specifically, two monomers), and (iii) the interaction of a dimer-gap with a constrained boundary (edge or corner).

The first of these types of interactions was later generalized by Kenyon [18] to an arbitrary number of dimer-gaps on the square and hexagonal lattices, and recently by Kenyon, Okounkov and Sheffield [20] to general planar bipartite lattices. Interactions of the second type were studied by the first author of the present paper in [4][5][6][8][7], where close analogies to two dimensional electrostatics were established.

†Research partially supported by NSF grant DMS-0500616.
‡Research partially supported by the Austrian Science Foundation FWF, grants Z130-N13 and S9607-N13, the latter in the framework of the National Research Network “Analytic Combinatorics and Probabilistic Number Theory.”
Two instances of interaction of non-dimer-gaps with constrained boundaries can be found in [19, Section 7.5] (interaction of a monomer with a constrained straight line boundary on the square lattice), and respectively [5, Theorem 2.2] (interaction of a family of triangular gaps with a constrained straight line boundary on the hexagonal lattice).

In this paper we determine the interaction of a triangular gap with a free straight line boundary (i.e., dimers are allowed to protrude out across it) on the hexagonal lattice. This type of interaction seems not to have been treated before in the literature. (We are aware of one other paper, namely [10], addressing the asymptotic behavior of lozenge tilings under the presence of a free boundary, but the regions considered there contain no gaps.) We find that the gap is attracted to the free boundary in precise analogy to the (two dimensional) electrostatic phenomenon in which an electric charge is attracted by a straight line conductor when placed near it.

This develops further the analogy between dimer systems with gaps and electrostatics that the first author has described in [5][6][8][7]. More generally, our result shows that in any physical system that can be modeled by dimer coverings, a gap will tend to be attracted to an interface corresponding to a free boundary. This effect, purely entropic in origin, is reminiscent of the Cheerios effect by which an air bubble at the surface of a liquid in a container is attracted to the walls [32] (note that the Cheerios effect is not entropic in origin).

2. Set-up and results

There seem to be no methods in the literature for finding the interaction of a gap “in a sea of dimers” with a free boundary. However, as V. I. Arnold said, “mathematics is a part of physics where experiments are cheap.” We now design such an experiment in order to determine the interaction of a gap in a dimer system on the hexagonal lattice with a free boundary.

Consider the tiling of the plane by unit triangles, drawn so that one family of lattice lines is vertical. Clearly, the hexagonal lattice can be viewed as the graph whose vertices are the unit triangles, and whose edges connect precisely those unit triangles that share an edge. Dimers on the hexagonal lattice are then (unit) lozenges (i.e., unit rhombi) consisting of pairs of adjacent unit triangles.

The free boundary we choose is a lattice line ℓ — say vertical — on the triangular lattice, to the left of which the plane is covered completely and without overlapping by lozenges, except for a gap ≪2 in the shape of a triangle of side-length 2, pointing to the left; the lozenges are allowed to protrude halfway across the free boundary, to its right (Figure 4 pictures a portion of such a tiling; the dotted lines should be ignored at this point).

We define the correlation function (or simply correlation) of the hole ≪2 with the free boundary ℓ as follows. Choose a rectangular system of coordinates in which ℓ is the y-axis, the origin is some lattice point on ℓ, and the unit is the lattice spacing. Let ≪2(k) be the placement of ≪2 so that the center C of its right side has coordinates (−k√3,0) (i.e., C and the origin are the endpoints of a string of k contiguous horizontal lozenges; Figure 4 illustrates ≪2(2), the origin being denoted by O there). Let $H_{n,x}$ be the lattice hexagon of side-lengths $2n$, $2n$, $2x$, $2n$, $2n$, $2x$ (in counterclockwise order, starting with the southwestern side) centered at the origin (thus $H_{n,x}$ is vertically symmetric about ℓ, and
its horizontal symmetry axis cuts $\prec_2(k)$ into two equal parts; for example, the boundary of
the region in Figure 3 is $H_{4,4}$. Let $F_{n,x}$ be the region obtained from the left half of $H_{n,x}$
by regarding its boundary along $\ell$ as free (i.e., lozenges in a tiling of $F_{n,x}$ are allowed to
protrude outward across $\ell$). Figure 1 shows the region $F_{3,3}$ together with such a lozenge
tiling; the origin is labelled by $O$.

![Figure 1](image.png)

Following in the spirit of [13] and [5], for any fixed integer $k \geq 0$ we define the correlation
of $\prec_2(k)$ with the free boundary $\ell$, denoted $\omega_f(k)$, by

$$
\omega_f(k) := \lim_{n \to \infty} \frac{M(F_{n,n} \setminus \prec_2(k))}{M(F_{n,n})},
$$

(2.1)

where $M(R)$ stands for the number of lozenge tilings of the region $R$ (if $R$ has portions of
the boundary that are free — as in our case — then it is understood that what we count is
tilings in which lozenges are allowed to protrude out across the free portions). A tiling of
$F_{4,4} \setminus \prec_2(2)$ of this type is illustrated in Figure 4.

We note that, by [9], lozenges have maximum entropy statistics (in the scaling limit)
at the center of a regular hexagon. According to this, (2.1) is a natural definition for the
correlation function. An analogous definition was used in [5].

In Lemma 13 (with $\xi = 1$) we obtain an exact expression for $\omega_f(k)$ in terms of an integral.
What affords this is an exact formula for $M(F_{n,x} \setminus \prec_2(k))$, which we present in Theorem 4.
We then deduce the asymptotics of $\omega_f(k)$ as $k \to \infty$ using Laplace’s method (see Theorem 15
with $\xi = 1$). The result is the following.
Theorem 1. As $k \to \infty$, we have

\[ \omega_f(k) \sim \frac{1}{4\pi d(\varphi_2(k), \ell)}, \]

(2.2)

where $d$ is the Euclidean distance.

Remark 1. In fact, our results allow us to determine the correlation of $\varphi_2(k)$ with the free boundary $\ell$ in a more general situation, namely when the sides $2n$ and $2x$ of $F_{n,x}$ grow to infinity so that $x/n \to 0$ a positive real number $\xi$ not necessarily equal to 1. This leads to the correlation $\omega_f(k; \xi)$ defined in (7.11). It turns out (see Theorem 15) that, for $\xi \neq 1$, the behavior of this correlation is exponential in $k$. This is in contrast to the behavior of the correlation of lozenges on the (“infinitely large”) torus, in which case Kenyon, Okounkov and Sheffield have shown in [20, Sec. 4.4] that the correlation decays polynomially. More precisely, it is shown in [20] that, for dimer models on doubly periodic bipartite planar graphs, there can only occur three different “phases” characterized by the behavior of edge-edge correlations: liquid, gaseous, and frozen. Our situation is readily seen to be in the liquid phase. The liquid phase is shown in [20] to be characterized by a polynomial decay of edge-edge correlations, and the arguments there imply that the correlation of holes of side 2 also have polynomial asymptotic behavior. It is this fact that is in contrast with the exponential interaction of Theorem 15. In fact, if one would define analogous generalized correlations for the lozenge tiling models in [4][5][6], one would observe the same phenomenon of exponential behavior of correlation if the correlation is not “measured” inside a patch of the lattice region in which all three types of lozenges occur with equal probability. This hints at the limitation of the transfer of properties of dimer models on the torus to dimer models of bounded regions in the plane, which is one of the main driving forces in [20]. We plan to address this phenomenon in more detail in forthcoming publications.

In [7] the first author described how a distribution of fixed holes on the triangular lattice defines in a natural way two vector fields. The $\mathbf{F}$-field is a discrete vector field defined at the center of each left-pointing unit triangle $e$, and equal to the expected orientation of the lozenge covering $e$ (under the uniform measure on the set of tilings). To define the $\mathbf{T}$-field, one introduces an extra “test-hole” $t$ and measures the relative change in the correlation function under small displacements of it, as the other holes are kept fixed. One can prove (details will appear elsewhere) that in the scaling limit of the lattice spacing approaching zero, this relative change is given by the scalar product of the displacement vector with a certain vector $\mathbf{T}(z)$, where $z$ is the point to which the test hole $t$ shrinks when the lattice spacing approaches zero. This defines the second field.

When these fields are generated by lozenge tilings that cover the entire plane with the exception of a finite collection of fixed-size holes (the case treated in [7] and [8]), both the $\mathbf{T}$-field and the scaling limit of the $\mathbf{F}$-field turn out to be equal, up to a constant multiple, to the electrostatic field of the two dimensional physical system obtained by viewing the holes as electrical charges.

But what if we do not tile the entire plane, but only the half-plane to the left of the free boundary $\ell$, and we have no holes?

The above definitions for the $\mathbf{F}$-field and $\mathbf{T}$-field would still work, provided (i) the scaling limit of the discrete field defining $\mathbf{F}$ exists, and (ii) the scaling limit of the relative changes
in the correlation function under small displacements of a test hole exists and is given by taking scalar products of the displacement vector with the vectors of a certain field.

Our exact determination of \( \omega_f(k) \) (see Lemma 13) allows us to verify (ii) for displacements along the horizontal direction. \( \omega_2(k) \) plays now the role of a test charge. We obtain the following result.

**Theorem 2.** We have
\[
\frac{\omega_f(k+1)}{\omega_f(k)} - 1 \sim -\frac{1}{k}, \quad k \to \infty.
\]  
(2.3)

**Remark 2.** By symmetry, displacements of \( \omega_2(k) \) parallel to \( \ell \) leave \( \omega_f \) unchanged, so the relative change in \( \omega_f \) corresponding to such displacements is zero. Thus, provided the field \( \mathbf{T} \) exists, it follows from Theorem 2 that its value at \( z \) is
\[
\mathbf{T}(z) = -\frac{i}{2d(z, \ell)},
\]  
(2.4)

where \( i \) is the unit vector in the positive direction of the \( x \)-axis (the 2 at the denominator comes from the fact that \( \mathbf{T} \) arises from the expression on the left hand side of (2.3) divided by the product of the displacement, \( \sqrt{3} \) in this case, and the “charge” of the hole \( \omega_2(k) \), which is 2; see [7] for details). Note that by [7] we would obtain (up to a multiplicative constant of 2) the same field \( \mathbf{T} \) at \( z \) if we look at tilings of the entire plane, with the mirror image of our test-hole \( \omega_2(k) \) being a fixed hole. This is analogous to the phenomenon in electrostatics by which the field created by an electric charge placed near a conductor can be obtained by the method of images (see e.g. [11, Chapter 6]).

The \( \mathbf{F} \)-field could be determined by an “experiment” analogous to the one we described at the beginning of this section. What one needs now is the number of lozenge tilings of \( F_{n,x} \setminus L(k) \), where \( L(k) \) is the horizontal lozenge contained in \( \omega_2(k) \). This turns out to be given by a formula very similar to (3.2), namely by
\[
M(F_{n,x} \setminus L(k)) = \left( \frac{n+k}{2k+1} \right)^2 \frac{(n-k-1)!}{(n-k)2k+1} \prod_{s=1}^{n-k} \frac{(2s+2s)4n-4s+1}{(2s)4n-4s+1} \\
\times \sum_{i=0}^{n-k-1} \frac{1}{(n+k-1)!} \left( \frac{1}{2} \right)_i \left( \frac{1}{2} \right)_i \cdot \left( (x)_i (x+i+1)_{n-k-i-1} (x+n+k+1)_{n-k} - (x)_{n-k} (x+n+k+1)_{n-k-i-1} (x+2n-i+1)_i \right).
\]  
(2.5)

In the same way as we derive Theorem 1 from Theorem 4 via Lemmas 12–14, Laplace’s method can be used to deduce from (2.5) the following result.

**Corollary 3.** Let \( e(k) \) be the leftmost left-pointing unit triangle of \( \omega_2(k) \). Then
\[
\mathbf{F}(e(k)) \sim o \left( \frac{1}{d(e(k), \ell)} \right), \quad k \to \infty.
\]  
(2.6)
Remark 3. Equations (2.4) and (2.6) imply that, in sharp contrast to the case of lozenge tilings of the plane with a finite number of fixed size holes, for the half-plane with free boundary the fields \( T \) and \( F \) have radically different behavior: while the former behaves as the electrostatic field near a conductor, the latter is zero in the scaling limit.

Our approach to proving Theorems 1 and 2 consists of solving first the counting problem exactly, see Theorem 4. This result generalizes Andrews’ theorem [1] (which proved MacMahon’s conjecture on symmetric plane partitions) in the case \( q = 1 \). Its proof is given in Sections 4 and 5, with some auxiliary results proved separately in Section 6. It is based on the “exhaustion/identification of factors” method described in [23, Sec. 2.4]. Finally, in Section 7, we perform the asymptotic calculations needed to derive Theorems 1 and 2 from the exact counting results.

3. An exact tiling enumeration formula

Tilings of the region \( F_{n,x} \) are clearly equivalent to tilings of the hexagon \( H_{n,x} \) that are invariant under reflection across its symmetry axis \( \ell \). Counting such tilings was a problem considered (in the equivalent form of symmetric plane partitions) by MacMahon in the early twentieth century (see [26, p. 270]). MacMahon conjectured that the number of vertically symmetric lozenge tilings of a hexagon with side lengths \( 2n, 2n, 2x, 2n, 2n, 2x \) is equal to

\[
\frac{(x + \frac{1}{2})_{2n} n}{(\frac{1}{2})_{2n}} \prod_{s=1}^{n} \frac{(2x + 2s)_{4n-4s+1}}{(2s)_{4n-4s+1}},
\]

(3.1)

where \( (\alpha)_m \) is the Pochhammer symbol, defined by \( (\alpha)_m := \alpha(\alpha + 1) \cdots (\alpha + m - 1) \) for \( m \geq 1 \), and \( (\alpha)_0 := 1 \). This was first proved by Andrews [1]. Other proofs, and refinements, were later found by e.g. Gordon [15], Macdonald [25, pp. 83–85], Proctor [29, Prop. 7.3], Fischer [12], and the second author of the present paper [21, Theorem 13].

Our “experiment” — counting \( M(F_{n,x} \setminus \triangle_2(k)) \) — is by the same token equivalent to counting vertically symmetric lozenge tilings of \( H_{n,x} \) with two missing triangles (compare Figures 3 and 4). This is in fact a generalization of MacMahon’s symmetric plane partitions problem (see Remark 4).

The key result that allows deducing Theorems 1 and 2 is the following.

Theorem 4. For all positive integers \( n, x \) and nonnegative integers \( k \leq n - 1 \), we have

\[
M(F_{n,x} \setminus \triangle_2(k)) = \binom{4k + 1}{2k} \frac{(n + k)!}{(x + n - k)_{2k+1}} \prod_{s=1}^{n} \frac{(2x + 2s)_{4n-4s+1}}{(2s)_{4n-4s+1}}
\]

\[
\times \sum_{i=0}^{n-k-1} \frac{1}{i! (n - k - i - 1)!^2 (n + k - i + 1)_{n-k} (n + k - i + 1)_{n-k} (2n - i + \frac{1}{2})_i}
\]

\[
\cdot \left( (x)_i (x + i + 1)_{n-k-i-1} (x + n + k + 1)_{n-k} - (x)_{n-k} (x + n + k + 1)_{n-k-i-1} (x + 2n - i + 1)_i \right) \quad (3.2)
\]

Remark 4. Replacing \( x \) by \( x - 1 \), \( n \) by \( n + 1 \), and \( k \) by \( n \), one can see that the above formula specializes to MacMahon’s formula (3.1). More precisely, because of forced lozenges
(see Figure 2), the enumeration problem in the statement of Theorem 4 reduces to the problem of enumerating vertically symmetric lozenge tilings of a hexagon with side lengths $2n, 2n, 2x, 2n, 2n, 2x$.

The proof of Theorem 4 is given in the next two sections. In Section 4, we show that $M(F_{n,x} \setminus \triangleleft_2(k))$ can be expressed in terms of a certain Pfaffian. This Pfaffian is then evaluated in Section 5.

4. LOZENGE TILINGS AND NONINTERSECTING LATTICE PATHS

The purpose of this section is to find a manageable expression for $M(F_{n,x} \setminus \triangleleft_2(k))$ (see Lemma 6 at the end of this section). In this context, we will find it more convenient to think of the tilings of $F_{n,x} \setminus \triangleleft_2(k)$ directly as tilings of a half hexagon with an open boundary (cf. Figure 4) as opposed to symmetric tilings of a hexagon with two holes (cf. Figure 3). There is a well known bijection between lozenge tilings of lattice regions and families of “paths of lozenges” (see Figure 4), which in turn are equivalent to families of non-intersecting lattice paths (see Figure 5). Its application to our situation is illustrated in Figures 4 and 5. The origin of the system of coordinates indicated in Figure 5 corresponds to the point $O'$ in Figure 4 (note that the bottommost path of lozenges in Figure 4 is empty for the illustrated

\[ \text{Forced lozenges when the hole touches the left border}\]

Figure 2
A symmetric lozenge tiling of the hexagon $H_{n,x}$ with two holes.

Figure 3

tiling; the corresponding lattice path in Figure 5 has no steps).

By this bijection, lozenge tilings of $F_{n,x} \setminus \mathcal{C}_2(k)$ are seen to be equinumerous with families $(P_1, P_2, \ldots, P_{2n})$ of non-intersecting lattice paths consisting of unit horizontal and vertical steps in the positive direction, where $P_i$ runs from $A_i = (-i, i)$ to some point from the set $I \cup \{S_1, S_2\}$, $i = 1, 2, \ldots, 2n$, with

$$
I = \{(-1, s) : s = 1, 2, \ldots, 2x + 2n\},
S_1 = (-2k - 1, x + n + k),
S_2 = (-2k - 2, x + n + k + 1),
$$

and the additional condition that $S_1$ and $S_2$ must be ending points of some paths.

At this point, we need a slight extension of Theorem 3.2 in [31] (which is, in fact, derivable from the minor summation formula of Ishikawa and Wakayama [17, Theorem 2]). The reader should recall that the Pfaffian of a skew-symmetric $2n \times 2n$ matrix $A$ can be defined by (see
A lozenge tiling of the region $F_{n,x} \setminus \phi_2(k)$; the right boundary is free. The dotted lines mark paths of lozenges. They determine the tiling uniquely.

Figure 4

e.g. [31, p. 102])

$$\text{Pf } A := \sum_{\pi \in M[1,\ldots,2n]} \text{sgn } \pi \prod_{i<j, \text{i,j matched in } \pi} A_{i,j}, \quad (4.2)$$

where $M[1,2,\ldots,2n]$ denotes the set of all perfect matchings (1-factors) of (the complete graph on) $\{1,2,\ldots,2n\}$, and where $\text{sgn } \pi = (-1)^{\text{cr}(\pi)}$, with $\text{cr}(\pi)$ denoting the number of “crossings” of $\pi$, that is, the number of quadruples $i < j < k < l$ such that, under $\pi$, $i$ is paired with $k$, and $j$ is paired with $l$. It is a well-known fact (see e.g. [31, Prop. 2.2]) that

$$(\text{Pf } A)^2 = \det A. \quad (4.3)$$

**Theorem 5.** Let $\{A_1, A_2, \ldots, A_p, S_1, S_2, \ldots, S_q\}$ and $I = \{I_1, I_2, \ldots\}$ be finite sets of lattice points in the integer lattice $\mathbb{Z}^2$. Then

$$\text{Pf} \left( \begin{array}{cc} Q & H \\ -H^t & 0 \end{array} \right) = (-1)^{\binom{|S|}{2}} \sum_{\pi \in S_p} (\text{sgn } \pi) \cdot P^{\text{nonint}}(A_{\pi} \rightarrow S \cup I), \quad (4.4)$$
The paths of lozenges of Figure 4 drawn as non-intersecting lattice paths on $\mathbb{Z}^2$.

Figure 5

where $A_\pi = (A_{\pi(1)}, A_{\pi(2)}, \ldots, A_{\pi(p)})$, and $P_{\text{nonint}}(A_\pi \rightarrow S \cup I)$ is the number of families $(P_1, P_2, \ldots, P_p)$ of non-intersecting lattice paths consisting of unit horizontal and vertical steps in the positive direction, with $P_k$ running from $A_{\pi(k)}$ to $S_k$, for $k = 1, 2, \ldots, q$, and to $I_{jk}$, for $k = q+1, q+2, \ldots, p$, the indices being required to satisfy $j_{q+1} < j_{q+2} < \cdots < j_p$. The matrix $Q = (Q_{i,j})_{1 \leq i, j \leq p}$ is defined by

$$Q_{i,j} = \sum_{1 \leq s < t} \left( P(A_i \rightarrow I_s) \cdot P(A_j \rightarrow I_t) - P(A_j \rightarrow I_s) \cdot P(A_i \rightarrow I_t) \right),$$

(4.5)

where $P(A \rightarrow E)$ denotes the number of lattice paths from $A$ to $E$, and the matrix $H = (H_{i,j})_{1 \leq i \leq p, 1 \leq j \leq q}$ by

$$H_{i,j} = P(A_i \rightarrow S_j).$$

In the special case when the starting and ending points satisfy a certain compatibility condition (called $D$-compatibility in [31]), the only permutation $\pi$ which contributes to the right-hand side of (4.4) is the identity permutation, and (4.4) reduces to [31, Theorem 3.2]. In our context, the compatibility condition is not satisfied. However, the same arguments that prove [31, Theorem 3.2] can be used to obtain (4.4). (Alternatively, one could use the minor summation formula of Ishikawa and Wakayama [17, Theorem 2]. In it, choose $m = p$, $r = q$, and the skew-symmetric matrix $B$ to be $B_{i,j} = 1$ for $i < j$ — which makes all principal
Pfaffian minors of $B$ equal 1 — to expand the Pfaffian on the left-hand side of (4.4) into a sum of minors of a certain matrix. Each minor can then be seen to count certain families of nonintersecting lattice paths by the general form of the Lindström–Gessel–Viennot theorem [24, Lemma 1], [14, Theorem 1], and, altogether, these are the families that are described in the statement of Theorem 5.)

We now apply Theorem 5 to our situation, that is, $p = 2n$, $q = 2$, $A_i = (-i, i)$, for $i = 1, 2, \ldots, 2n$, and $S_1$, $S_2$, and $I$ are given by (4.1). It is not difficult to convince oneself that, for this choice of starting and ending points, all families of nonintersecting lattice paths counted on the right-hand side of (4.4) give rise to even permutations $\pi$. Hence, the right-hand side of (4.4) counts indeed the families of nonintersecting lattice paths that we need to count. By Theorem 5, their number is equal to the negative value of the Pfaffian of

$$M_n(x) := \begin{pmatrix} Q & H \\ -H^t & 0 \end{pmatrix},$$

(4.6)

where $Q$ is a $(2n) \times (2n)$ skew-symmetric matrix with $(i, j)$-entry $Q_{i,j}$ given by (4.5), and where $H$ is a $(2n) \times 2$ matrix, in which the $(i, j)$-entry $H_{i,j}$ is equal to the number of paths from $A_i$ to $S_j$, $i = 1, 2, \ldots, 2n$, $j = 1, 2$. (It is the negative value of the Pfaffian because of the sign $(-1)^{\binom{q}{2}}$ on the right-hand side of (4.4), as we have $q = 2$.)

In particular, using the fact that the number of lattice paths on the integer lattice $\mathbb{Z}^2$ between two given lattice points is given by a binomial coefficient, we have

$$H_{i,1} = \binom{x + n - k - 1}{i - 2k - 1},$$

(4.7)

$$H_{i,2} = \binom{x + n - k - 1}{i - 2k - 2}.$$

(4.8)

On the other hand, substituting $A_i = (-i, i)$ and $I_s = (-1, s)$ in (4.5), we have

$$Q_{i,j} = \sum_{1 \leq s < t \leq 2x+2n} (|P(A_i \rightarrow I_s)| \cdot |P(A_j \rightarrow I_t)| - |P(A_j \rightarrow I_s)| \cdot |P(A_i \rightarrow I_t)|)$$

$$= \sum_{1 \leq s < t \leq 2x+2n} \left( \binom{s - 1}{i - 1} \binom{t - 1}{j - 1} - \binom{s - 1}{j - 1} \binom{t - 1}{i - 1} \right)$$

$$= \sum_{1 \leq s < t \leq 2x+2n} \binom{s - 1}{i - 1} \binom{t - 1}{j - 1} - \sum_{1 \leq s \leq t \leq 2x+2n} \binom{s - 1}{j - 1} \binom{t - 1}{i - 1}$$

$$= \sum_{1 \leq t \leq 2x+2n} \binom{t}{i} \binom{t - 1}{j - 1} - \sum_{1 \leq t \leq 2x+2n} \binom{t}{j} \binom{t - 1}{i - 1}$$

$$= \sum_{t=1}^{2x+2n} \frac{j - i}{t} \binom{t}{i} \binom{t}{j},$$

(4.9)

$$= \sum_{t=0}^{X} \binom{t}{i - 1} = \binom{X + 1}{i},$$

(4.10)

where we used the well-known identity

$$\sum_{t=0}^{X} \binom{t}{i - 1} = \binom{X + 1}{i}$$

(4.11)
to obtain (4.9). We may obtain an alternative expression for \( Q_{i,j} \) by replacing \( \frac{1}{t} \binom{t}{i} = \frac{1}{t} \binom{t-1}{i-1} \) in the last expression by \( \frac{1}{i} \sum_{l=0}^{i-1} \binom{i-l}{j} \binom{j-l}{t} \), this equality being true because of the Chu–Vandermonde summation (cf. e.g. [16, Sec. 5.1, (5.27)]). Thus, we arrive at

\[
Q_{i,j} = \sum_{l=0}^{i-1} \sum_{t=1}^{2x+2n} \frac{j-i}{i} \binom{j-t}{l} \binom{j-1}{i-l-1} \binom{t}{j}
\]

\[
= \sum_{l=0}^{i-1} \sum_{t=1}^{2x+2n} \frac{j-i}{i} \binom{j-1}{i-l-1} \binom{l+j}{l} \binom{t}{l+j}
\]

\[
= \sum_{l=0}^{i-1} \frac{j-i}{i} \binom{j-1}{i-l-1} \binom{l+j}{l} \binom{2x+2n+1}{l+j+1},
\]

(4.12)

the last line again being due to (4.11).

To summarize, we have obtained the following result.

**Lemma 6.** For all positive integers \( n, x \) and nonnegative integers \( k \), we have

\[
M(F_{n,x} \setminus \triangleleft_2(k)) = - \text{Pf} M_n(x),
\]

(4.13)

where \( M_n(x) \) is given by (4.6), with \( Q_{i,j} \) defined in (4.10) or (4.12), and \( H_{i,j} \) defined in (4.7) and (4.8).

### 5. Proof of Theorem 4

In the sequel, we shall interpret sums by

\[
\sum_{k=m}^{n-1} \text{Expr}(k) = \begin{cases} 
\sum_{k=m}^{n-1} \text{Expr}(k) & n > m \\
0 & n = m \\
-\sum_{k=n}^{m-1} \text{Expr}(k) & n < m.
\end{cases}
\]

(5.1)

In particular, using this convention, the expression for \( Q_{i,j} \) given in (4.10) makes sense for negative integers \( x \) also (in which case the upper bound in the sum can be negative) and is actually equal to the expression in (4.12). It is the latter fact that we shall frequently make use of.

Our proof of Theorem 4 involves a sequence of five steps. By Lemma 6, we know that the number that we want to compute is the negative of a Pfaffian. We shall frequently use the fact (4.3) that the square of the Pfaffian of a skew-symmetric matrix is equal to its determinant.

By its definition, \( \text{Pf} M_n(x) \) is a polynomial in \( x \). In Step 1 we prove that

\[
\det M_n(x) = \det M_n(-2n - x).
\]

With \( d \) denoting the degree of \( \text{Pf} M_n(x) \) as a polynomial in \( x \), this implies that

\[
\text{Pf} M_n(x) = (-1)^d \text{Pf} M_n(-2n - x).
\]

(5.2)
Subsequently, in Step 2 we show that
\[
\prod_{s=1, s \neq n-k}^{n} (x + s)_{2n-2s+1}^{2}
\]
divides \( \det M_n(x) \) as a polynomial in \( x \), while in Step 3 we show that
\[
\prod_{s=1}^{n-1} \left( x + s + \frac{1}{2} \right)_{2n-2s}^{2}
\]
divides \( \det M_n(x) \). Both combined, this proves that
\[
\prod_{s=1, s \neq n-k}^{n} (x + s)_{2n-2s+1}^{2} \prod_{s=1}^{n-1} \left( x + s + \frac{1}{2} \right)_{2n-2s}^{2},
\]
which is a polynomial of degree
\[
\sum_{s=1}^{n} (4n - 4s + 1) - (2k + 1) = n(2n - 1) - (2k + 1),
\]
divides \( \text{Pf } M_n(x) \) as a polynomial in \( x \). The computation in Step 4 then shows that the degree of \( \text{Pf } M_n(x) \), as a polynomial in \( x \), is at most \( 2n^2 + n - 4k - 3 \). Altogether, this implies that
\[
- \text{Pf } M_n(x) = P_n(x) \prod_{s=1, s \neq n-k}^{n} (x + s)_{2n-2s+1}^{2} \prod_{s=1}^{n} \left( x + s + \frac{1}{2} \right)_{2n-2s}^{2},
\]
where \( P_n(x) \) is a polynomial in \( x \) of degree at most
\[
2n^2 + n - 4k - 3 - n(2n - 1) + (2k + 1) = 2n - 2k - 2.
\]

In Step 5, we determine the value of \( P_n(x) \) at \( x = 0, -1, \ldots, -n + k + 1 \) (see (5.29)). The corresponding calculations make use of an auxiliary lemma due to Mehta and Wang [27], see Theorem 7 and Corollary 10 in Section 6. By (5.2), this gives us at the same time the value of \( P_n(x) \) at \( x = -2n, -2n + 1, \ldots, -n - k - 1 \). In total, these are \( 2n - 2k \) explicit evaluations of \( P_n(x) \) at special values of \( x \). Given the fact that the degree of \( P_n(x) \) is at most \( 2n - 2k - 2 \), they determine \( P_n(x) \) uniquely, and an explicit expression for \( P_n(x) \) can be written down using Lagrange interpolation. If this is substituted into (5.3), then the evaluation of \( - \text{Pf } M_n(x) \) is complete. After some manipulations, one arrives at the expression in (3.2).

**Step 1.** \( \det M_n(x) = \det M_n(-2n-x) \). We prove this claim by transforming, up to sign, \( M_n(x) \) into \( M_n(-2n-x) \) by a sequence of elementary row and column operations (which, of
course, leave the value of the determinant invariant). To be precise, for \( i = 2n, 2n - 1, \ldots, 2 \) (in this order), we add

\[
\sum_{a=1}^{i-1} \binom{i-1}{a-1} \cdot \text{(row } a) \tag{5.4}
\]

to row \( i \), and then for \( j = 2n, 2n - 1, \ldots, 2 \), we add

\[
\sum_{b=1}^{j-1} \binom{j-1}{b-1} \cdot \text{(column } b) \tag{5.5}
\]

to column \( j \). Let \( M_n^{(1)}(x) \) denote the matrix which arises after these row and column operations. According to (4.9), the \((i, j)\)-entry in \( M_n^{(1)}(x) \) is

\[
\sum_{a=1}^{i} \sum_{b=1}^{j} \binom{i-1}{a-1} \binom{j-1}{b-1} 2^{t+2n} \sum_{t=1}^{t} \left( \binom{t}{a} \binom{t-1}{b-1} - \binom{t-1}{a-1} \binom{t}{b} \right) \tag{5.4}
\]

for \( 1 \leq i, j \leq 2n \). By (4.7) and (4.8), for \( 1 \leq i \leq 2n \) and \( j = 2n + \varepsilon, \varepsilon = 1, 2 \), the \((i, j)\)-entry of \( M_n^{(1)}(x) \) is

\[
\sum_{a=1}^{i} \binom{i-1}{a-1} \binom{x + n - k - 1}{a - 2k - \varepsilon} \tag{5.5}
\]

and, for \( 1 \leq j \leq 2n \) and \( i = 2n + \varepsilon, \varepsilon = 1, 2 \), it is

\[
- \sum_{b=1}^{j} \binom{j-1}{b-1} \binom{x + n - k - 1}{b - 2k - \varepsilon}. \tag{5.6}
\]

By Chu–Vandermonde summation, we have

\[
\sum_{a=1}^{i} \binom{i-1}{a-1} \binom{t + \gamma}{a + \eta} = \sum_{a=1}^{i} \binom{i-1}{i-a} \binom{t + \gamma}{a + \eta} = \binom{t + i + \gamma - 1}{i + \eta},
\]
whence the expression (5.4) simplifies to
\[
\sum_{t=1}^{2x+2n} \left( \binom{t+i-1}{i} \binom{t+j-2}{j-1} - \binom{t+i-2}{i-1} \binom{t+j-1}{j} \right)
\]
\[
= \sum_{t=-2x-2n}^{-1} \left( \binom{-t+i-1}{i} \binom{-t+j-2}{j-1} - \binom{-t+i-2}{i-1} \binom{-t+j-1}{j} \right)
\]
\[
= (-1)^{i+j-1} \sum_{t=-2x-2n}^{-1} \left( \binom{t+1}{i} \binom{t}{j-1} - \binom{t}{i-1} \binom{t+1}{j} \right)
\]
\[
= (-1)^{i+j} \sum_{t=0}^{-2x-2n-1} \left( \binom{t+1}{i} \binom{t}{j-1} - \binom{t}{i-1} \binom{t+1}{j} \right)
\]
\[
= (-1)^{i+j} \sum_{t=1}^{-2x-2n} \left( \binom{i}{i} \binom{t-1}{j-1} - \binom{t-1}{i-1} \binom{t}{j} \right).
\]

Here, we used the identity
\[
\binom{t}{i} \binom{t}{j} - \binom{t}{i-1} \binom{t}{j} = \binom{t}{i} \binom{t}{j-1} - \binom{t}{i-1} \binom{t+1}{j}
\]
\[
= \binom{t+1}{i} \binom{t}{j-1} - \binom{t}{i-1} \binom{t+1}{j}
\]
to obtain (5.7), and our convention (5.1) for sums to obtain (5.8). Comparison with (4.9) shows that this last expression is, up to the sign \((-1)^{i+j}\), exactly \(Q_{i,j}\) with \(x\) replaced by \(-2n-x\). In a similar vein, the expression (5.5) simplifies to
\[
\left( x + n + i - k - 2 \atop i - 2k - \varepsilon \right) = (-1)^{i+\varepsilon} \left( -x - n - k + 1 - \varepsilon \atop i - 2k - \varepsilon \right),
\]
while expression (5.6) simplifies to the same expression with \(i\) replaced by \(j\). Upon setting \(\varepsilon = 2\), this shows that the \((i, 2n+2)\)-entry in \(M_n^{(1)}(x)\) is, up to the sign \((-1)^i\), identical with the \((i, 2n+2)\)-entry in \(M_n(-2n-x)\), with an analogous statement being true for the \((2n+2, j)\)-entry of \(M_n^{(1)}(x)\) and the \((2n+2, j)\)-entry of \(M_n(-2n-x)\).

We do one last row and one last column operation: in \(M_n^{(1)}(x)\), we add the last row to the next-to-last row, and we add the last column to the next-to-last column. Let \(M_n^{(2)}(x)\) denote the resulting matrix. By (5.10), for \(i = 1, 2, \ldots, 2n\), the \((i, 2n+1)\)-entry of \(M_n^{(2)}(x)\) is equal to
\[
(-1)^{i+1} \left( -x - n - k \atop i - 2k - 1 \right) + (-1)^i \left( -x - n - k - 1 \atop i - 2k - 2 \right) = (-1)^{i+1} \left( -x - n - k - 1 \atop i - 2k - 1 \right),
\]

(5.11)
which is, up to the sign \((-1)^{i+1}\), exactly the \((i, 2n+1)\)-entry in \(M_n(-2n-x)\). An analogous statement is true for the \((2n+1, j)\)-entries of \(M_n^{(2)}(x)\) and \(M_n(-2n-x)\).

In summary, as the two by two block in the lower right corner of \(M_n(x)\) consists of zeros, the computations (5.9)–(5.11) show that the \((i, j)\)-entry of \(M_n^{(2)}(x)\) is \((-1)^{i+j}\) times the \((i, j)\)-entry of \(M_n(-2n-x)\). This implies

\[
\det M_n(x) = \det M_n^{(2)}(x) = \det M_n(-2n-x),
\]
as claimed.

**Step 2.** \(\prod_{s=1, \thinspace s \neq n-k}^{n} (x+s)^2\) divides \(\det M_n(x)\). We begin by observing that the product in the claim can be also rewritten as

\[
\prod_{s=1, \thinspace s \neq n-k}^{n} (x+s)^2 = \prod_{s=1}^{n} (x+s)^{2s+2\chi(s<n-k)-2} \prod_{s=n+1}^{2n-1} (x+s)^{4n-2s+2\chi(s>n+k)-2}, \tag{5.12}
\]

where \(\chi(A) = 1\) if \(A\) is true and \(\chi(A) = 0\) otherwise. In view of Step 1, it suffices to establish that

\[
\prod_{s=1}^{n} (x+s)^{2s+2\chi(s<n-k)-2}
\]

divides \(\det M_n(x)\).

Now let \(s, a\) and \(b\) be integers with \(1 \leq s \leq n\) and \(1 \leq a \leq b \leq 2n\). We claim that

\[
\sum_{i=a}^{b} \binom{b-a}{i-a} Q_{i,j} \text{ (row } i \text{ of } M_n(-s)) = 0, \tag{5.13}
\]
as long as

(A) \(a - b \leq 2n - 2s < a\), and

(B) either \(b \leq 2k\), or \(b \geq 2k+3\) and \(a - b + k + 1 \leq n - s < a - k - 1\).

Indeed, if we specialize (5.13) to the \(j\)-th column, where \(j \leq 2n\), we obtain, using the expression (4.10) for \(Q_{i,j}\),

\[
\sum_{i=a}^{b} \binom{b-a}{i-a} Q_{i,j} = \sum_{i=a}^{b} \binom{b-a}{i-a} \sum_{t=1}^{2n-2s} \frac{j-i}{t} \binom{t}{i} \binom{t}{j}
\]

\[
= \sum_{t=1}^{2n-2s} \sum_{i=a}^{b} \binom{b-a}{b-i} \left( \binom{t}{i} \binom{t-1}{j-1} - \binom{t-1}{i-1} \binom{t}{j} \right)
\]

\[
= \sum_{t=1}^{2n-2s} \left( \binom{b-a+t}{b} \binom{t-1}{j-1} - \binom{b-a+t-1}{b-1} \binom{t}{j} \right). \tag{5.14}
\]
Here we used Chu–Vandermonde summation (cf. [16, Sec. 5.1, (5.27)]) in the last line. Since, for \( a - b \leq 2n - 2s < a \) (which is condition (A)), the binomial coefficients containing the parameter \( b \) in expression (5.14) are identically zero throughout the summation range, it is clear that the corresponding sum vanishes.

On the other hand, if we specialize (5.13) to the \((2n + 1)\)-st column, we obtain, again using Chu–Vandermonde summation,

\[
\sum_{i=a}^{b} \binom{b-a}{i-a} H_{i,1} \bigg|_{x=-s} = \sum_{i=a}^{b} \binom{b-a}{b-i} \binom{n-s-k-1}{i-2k-1} = \binom{b-a+n-s-k-1}{b-2k-1},
\]

which vanishes for \( b \leq 2k \), and for \( b \geq 2k + 2 \) and \( 0 \leq b-a+n-s-k-1 < b-2k-1 \), the last inequality being equivalent to \( a-b+k+1 \leq n-s < a-k \), and if we specialize (5.13) to the \((2n + 2)\)-nd column, we obtain

\[
\sum_{i=a}^{b} \binom{b-a}{i-a} H_{i,2} \bigg|_{x=-s} = \sum_{i=a}^{b} \binom{b-a}{b-i} \binom{n-s-k-1}{i-2k-2} = \binom{b-a+n-s-k-1}{b-2k-2},
\]

which vanishes for \( b \leq 2k-1 \), and for \( b \geq 2k+3 \) and \( 0 \leq b-a+n-s-k-1 < b-2k-2 \), the last inequality being equivalent to \( a-b+k+1 \leq n-s < a-k-1 \). This establishes our claim.

In order to prove that \((x+s)^{2s}\) divides \(\det M_n(x)\) for \(1 \leq s < n-k\), we use (5.13) with \(a = 2n - 2s + 1\) and \(2n - 2s + 1 \leq b \leq 2n\). It is not difficult to see that for these choices of \(s\), \(a\) and \(b\) the conditions (A) and (B) are satisfied, so that we obtain \(2s\) linear combinations of the rows that are linearly independent (as, for our choices of \(a\) and \(b\), the coefficients in (5.13) form a triangular array) and vanish when \(x = -s\). This implies divisibility by \((x+s)^{2s}\) (cf. e.g. [22, Lemma in Sec. 2]).

To prove that \((x+s)^{2s-2}\) divides \(\det M_n(x)\) for \(n-k \leq s \leq n\), we use (5.13) with \(a = 2n - 2s + 1\) and \(2n - 2s + 1 \leq b \leq 2k\) on the one hand, and with \(a = n+k-s+2\) and \(2k+3 \leq b \leq 2n\) on the other hand. Again, it is not difficult to see that for both types of choices of \(s\), \(a\) and \(b\) the conditions (A) and (B) are satisfied, so that we obtain \((2k+2s-2n) + (2n-2k-2) = 2s-2\) linear combinations of the rows that are linearly independent and vanish at \(x = -s\). In the same way as before, this implies divisibility by \((x+s)^{2s-2}\).

**Step 3.** \(\prod_{s=1}^{n-1} (x+s+\frac{1}{2})^{2n-2s} \) divides \(\det M_n(x)\). We begin by observing that the product in the claim can be also rewritten as

\[
\prod_{s=1}^{n-1} (x+s+\frac{1}{2})^{2n-2s} = \prod_{s=1}^{n-1} (x+s+\frac{1}{2})^{2s} \prod_{s=n}^{2n-2} (x+s+\frac{1}{2})^{4n-2s-2}.
\]
In view of Step 1, it suffices to establish that
\[
\prod_{s=1}^{n-1} (x + s + \frac{1}{2})^{2s}
\]
divides \( \det M_n(x) \).

In order to prove the claim for \( s < n - k \), we shall show that
\[
(n - s - k) \cdot (\text{row } (2n - 2s + 1) \text{ of } M_n(-s - \frac{1}{2}))
+ \frac{1}{2} (n - s - k) \cdot (\text{row } (2n - 2s) \text{ of } M_n(-s - \frac{1}{2}))
+ \sum_{i=1}^{2n-2s-1} \frac{(-1)^i}{2^{2n-2s-i+2}} (\text{row } i \text{ of } M_n(-s - \frac{1}{2})) = 0,
\]
and that
\[
(\text{row } i \text{ of } M_n(-s - \frac{1}{2})) + \frac{2i + 2s - 2n - 2k - 3}{i - 2k - 1} (\text{row } (i - 1) \text{ of } M_n(-s - \frac{1}{2}))
+ \frac{(2i + 2s - 2n - 2k - 3)(2i + 2s - 2n - 2k - 5)}{4(i - 2k - 1)(i - 2k - 2)} (\text{row } (i - 2) \text{ of } M_n(-s - \frac{1}{2})) = 0
\]
for \( i = 2n - 2s + 2, 2n - 2s + 3, \ldots, 2n \). As these are linearly independent row combinations, the claim will follow.

In order to prove the claim for \( s \geq n - k \), we shall show that
\[
\sum_{i=1}^{2n-2s-1} \frac{(-1)^i}{2^{2n-2s-i+1}} (\text{row } i \text{ of } M_n(-s - \frac{1}{2})) = 0,
\]
that
\[
(\text{row } i \text{ of } M_n(-s - \frac{1}{2})) = 0
\]
for \( i = 2n - 2s, 2n - 2s + 1, \ldots, 2k \), and that
\[
(\text{row } i \text{ of } M_n(-s - \frac{1}{2})) + \frac{2i + 2s - 2n - 2k - 3}{i - 2k - 1} (\text{row } (i - 1) \text{ of } M_n(-s - \frac{1}{2}))
+ \frac{(2i + 2s - 2n - 2k - 3)(2i + 2s - 2n - 2k - 5)}{4(i - 2k - 1)(i - 2k - 2)} (\text{row } (i - 2) \text{ of } M_n(-s - \frac{1}{2})) = 0
\]
for \( i = 2k + 3, 2k + 4, \ldots, 2n \). Again, as these are linearly independent row combinations, the claim will follow.

Let first \( s \geq n - k \). We start with the proof of (5.17). Specializing (5.17) to the \( j \)-th column, \( j = 1, 2, \ldots, 2n \), by (4.9) we see that we must prove the identity
\[
\sum_{i=1}^{2n-2s-1} \frac{(-1)^i}{2^{2n-2s-i+1}} \left( \sum_{t=1}^{2n-2s-1} \binom{t}{i} \binom{t-1}{j-1} - \sum_{t=1}^{2n-2s-1} \binom{t-1}{i-1} \binom{t}{j} \right) = 0.
\]
In order to see that this is indeed true, we first extend the sum over \( i \) to the range \( i = 0, 1, \ldots, 2n - 2s - 1 \), thereby obtaining

\[
\sum_{i=0}^{2n-2s-1} \frac{(-1)^i}{2^{2n-2s-i-1}} \left( \sum_{t=1}^{2n-2s-1} \binom{t}{i} \binom{t-1}{j-1} \right) - \sum_{t=1}^{2n-2s-1} \binom{t-1}{i} \binom{t}{j} - \frac{1}{2^{2n-2s-1}} \sum_{t=1}^{2n-2s-1} \binom{t-1}{j-1}
\]

for the left-hand side of (5.20). Next we interchange the sum over \( i \) with the sums over \( t \), and subsequently we evaluate the (now inner) sums over \( i \) by means of the binomial theorem. In this manner, the left-hand side of (5.20) becomes

\[
\frac{1}{2^{2n-2s-1}} \sum_{t=1}^{2n-2s-1} (1 - 2)^t \binom{t-1}{j-1} + \frac{1}{2^{2n-2s-2}} \sum_{t=1}^{2n-2s-1} (1 - 2)^{t-1} \binom{t}{j} - \frac{1}{2^{2n-2s-1}} \binom{2n-2s-1}{j}
\]

\[
= \sum_{t=1}^{2n-2s-1} (-1)^t \frac{1}{t!} \binom{t}{j} \binom{t}{j} + \frac{1}{2^{2n-2s-1}} \binom{2n-2s-1}{j}
\]

\[
= -\frac{1}{2^{2n-2s-1}} \left( \sum_{t=1}^{2n-2s-1} (-1)^t \left( \binom{t}{j} + \binom{t-1}{j} \right) \right) = 0,
\]

as desired.

On the other hand, specializing (5.17) to the \( j \)-th column, \( j = 2n + 1, 2n + 2 \), by (4.7) and (4.8) we obtain

\[
\sum_{i=1}^{2n-2s-1} \frac{(-1)^i}{2^{2n-2s-i-1}} \binom{n-k-s-\frac{3}{2}}{i-2k-\varepsilon},
\]

where \( \varepsilon = 1, 2 \), which is indeed zero since the binomial coefficient always vanishes because of \( i \leq 2n - 2s - 1 < 2k + \varepsilon \), the last inequality being due to our assumption \( s \geq n - k \).

That (5.18) holds can be easily checked by inspection.

For the proof of (5.19), we observe that we have \( Q_{i,j} \big|_{x=-s-\frac{1}{2}} = 0 \) for all \( i \geq 2n - 2s \), because in this case the appearance of the binomial coefficient \( \binom{t}{i} \) in the sum in formula (4.10) implies that all summands of this sum vanish. In its turn, this entails that the left-hand side of (5.19) specialized to the \( j \)-th column, where \( 1 \leq j \leq 2n \), is trivially zero since

\[
i > i - 1 > i - 2 \geq 2k + 1 \geq 2n - 2s + 1 > 2n - 2s,
\]
by our assumptions. To see that the left-hand side of (5.19) is as well zero when it is specialized to the \((2n + 1)\)-st or \((2n + 2)\)-nd column amounts to a routine verification using the expressions (4.7) and (4.8) for the corresponding matrix entries.

We now assume that \(s < n - k\) and turn our attention to (5.15). The reader should notice that the relations (5.15) and (5.17) are relatively similar, the essential difference being the two extra terms in (5.15) corresponding to the \((2n - 2s)\)-th and the \((2n - 2s + 1)\)-st row, respectively. If \(1 \leq j \leq 2n\), the proof of relation (5.15) specialized to column \(j\) is therefore identical with the proof of relation (5.17) specialized to column \(j\), because the entries in the first \(2n\) columns of the \((2n - 2s)\)-th and the \((2n - 2s + 1)\)-st row evaluated at \(x = -s - \frac{1}{2}\) are all zero. (The reader should recall formula (4.10).) To show the relation (5.15) specialized (cf. [30, (1.7.1.9); Appendix (III.6)]) to \(c_{n}^{s}\) in standard hypergeometric notation

\[
\frac{(n - s - k)(\varepsilon - 2)}{2} \cdot \frac{(-n + s + k + \varepsilon - \frac{1}{2})_{2n - 2s - 2k - \varepsilon}}{(2n - 2s - 2k - \varepsilon + 1)!} \sum_{i=1}^{2n-2s-1} \frac{(-1)^i}{2^{2n-2s-i+2}} \left( \frac{n - s - k - \frac{3}{2}}{i - 2k - \varepsilon} \right) = 0. \tag{5.21}
\]

We reverse the order of summation in the sum over \(i\) (that is, we replace \(i\) by \(2n - 2s - i - 1\), and subsequently we write the (new) sum over \(i\) in standard hypergeometric notation

\[
_{p}F_{q} \left[ \begin{array}{c} a_{1}, \ldots, a_{p} \\ b_{1}, \ldots, b_{q} \end{array} ; z \right] = \sum_{m=0}^{\infty} \frac{(a_{1})_{m} \cdots (a_{p})_{m}}{m! (b_{1})_{m} \cdots (b_{q})_{m}} z^{m}. \tag{5.22}
\]

Thereby we obtain

\[
\frac{(n - s - k)(\varepsilon - 2)}{2} \cdot \frac{(-n + s + k + \varepsilon - \frac{1}{2})_{2n - 2s - 2k - \varepsilon}}{(2n - 2s - 2k - \varepsilon + 1)!} \left( -\frac{(-n + k + s + \varepsilon + \frac{1}{2})_{2n - 2s - 2k - \varepsilon - 1}}{8 (2n - 2s - 2k - \varepsilon - 1)!} \right) _{2}F_{1} \left[ \begin{array}{c} 1, -2n + 2k + 2s + \varepsilon + 1 \\ -n + k + s + \varepsilon + \frac{1}{2} \end{array} ; \frac{1}{2} \right] \tag{5.23}
\]

for the left-hand side of (5.21).

If \(\varepsilon = 2\), then the \(_2F_1\)-series in (5.23) can be evaluated using Gauß' second \(_2F_1\)-summation (cf. [30, (1.7.1.9); Appendix (III.6)])

\[
_{2}F_{1} \left[ \begin{array}{c} a, -N \\ \frac{1}{2} + \frac{a}{2} - \frac{N}{2} \end{array} ; \frac{1}{2} \right] = \left\{ \begin{array}{ll} 0 & \text{if } N \text{ is an odd nonnegative integer,} \\ \left( \frac{1}{2} \right)^{N/2} & \text{if } N \text{ is an even nonnegative integer.} \end{array} \right. \tag{5.24}
\]
As a result, in this case, the expression (5.23) vanishes, whence (5.21) with \( \varepsilon = 2 \) is satisfied, and thus relation (5.15) specialized to the \((2n + 2)\)-nd column.

If \( \varepsilon = 1 \), the \( \mathbf{2}F_{1} \)-series in (5.23) cannot be directly evaluated by means of Gauß’ formula. However, we may in a first stage apply the contiguous relation

\[
\mathbf{2}F_{1}\left[a, b; c; z\right] = \mathbf{2}F_{1}\left[a, b - 1; c; z\right] + \frac{az}{c} \mathbf{2}F_{1}\left[a + 1, b; c + 1; z\right]
\]

to transform (5.23) into

\[
- \frac{(n - s - k)}{2} \cdot \frac{(-n + s + k + \frac{1}{2})_{2n - 2s - 2k - 1}}{(2n - 2s - 2k)!} \cdot \left( \mathbf{2}F_{1}\left[1, -2n + 2k + 2s + 1; 1; \frac{3}{2} - n + k + s\right] - \frac{1}{2n - 2k - 2s - 3} \mathbf{2}F_{1}\left[2, -2n + 2k + 2s + 2; 1; \frac{3}{2} - n + k + s\right] \right).
\]

Both \( \mathbf{2}F_{1} \)-series in the last expression can now be evaluated by means of Gauß’ formula (5.24). The first series simply vanishes, while the second series evaluates to a non-zero expression. If this is substituted, after some simplification we obtain

\[
- \frac{(n - s + k + \frac{1}{2})_{2n - 2s - 2k - 1}}{4 (2n - 2s - 2k - 1)!} - \frac{(-n + k + s + \frac{3}{2})_{2n - 2s - 2k - 2}}{8 (2n - 2s - 2k - 2)!} = 0.
\]

This shows that for \( \varepsilon = 1 \) the expression (5.23) vanishes as well, whence (5.21) with \( \varepsilon = 1 \) is satisfied, and thus also relation (5.15) specialized to the \((2n + 1)\)-st column.

The verification of (5.16) is completely analogous to that of (5.19) and is left to the reader.

**Step 4.** \( \text{Pf} M_{n}(x) \) is a polynomial in \( x \) of degree at most \( 2n^{2} + n - 4k - 3 \). By (4.12), \( Q_{i,j} \) is a polynomial in \( x \) of degree \( i + j \). On the other hand, the degree of \( H_{i,1} \) in \( x \) is clearly \( i - 2k - 1 \), while the degree of \( H_{i,2} \) is \( i - 2k - 2 \). It follows that, in the defining expansion of the determinant \( \det M_{n}(x) \), each nonzero term has degree

\[
\sum_{i=1}^{2n} i + \sum_{j=1}^{2n} j - 2(2k + 1) - 2(2k + 2) = 4n^{2} + 2n - 8k - 6.
\]

The Pfaffian being the square root of the determinant (cf. (4.3)), the claim follows.

**Step 5.** Evaluation of \( P_{n}(x) \) at \( x = 0, -1, \ldots, -n + k + 1 \). The polynomial \( P_{n}(x) \) is defined by means of (5.3). So, what we would like to do is to set \( x = -s \) in (5.3), \( s \) being one of \( 0, 1, \ldots, n - k - 1 \), evaluate \( \text{Pf} M_{n}(-s) \), divide both sides of (5.3) by the products on the right-hand side of (5.3), and get the evaluation of \( P_{n}(x) \) at \( x = -s \). However, the first product on the right-hand side of (5.3) unfortunately is zero for \( x = -s \), \( 1 \leq s \leq n - k - 1 \). (It is not zero for \( s = 0 \).) Therefore we have to find a way around this difficulty.
Fix an \( s \) with \( 1 \leq s \leq n - k - 1 \). Before setting \( x = -s \) in (5.3), we have to cancel \( (x + s)^s \) (see (5.12)) on both sides of (5.3). That is, we should write (5.3) in the form

\[
P_n(x) = -\frac{1}{(x+s)^s} \text{Pf} M_n(x) \times \prod_{\ell=1}^{n-k-1} (x + \ell)^{-\ell} \prod_{\ell=n-k+1}^{n} (x + \ell)^{-\ell+1} \prod_{\ell=n+1}^{2n-1} (x + \ell)^{-2n+\ell-\chi(\ell>n+k)+1} \prod_{\ell=1}^{n} (x + \ell + \frac{1}{2})^{-1}_{2n-2\ell}, \tag{5.25}\]

and subsequently specialize \( x = -s \). However, in order to be able to perform this step, we need to evaluate \(-\left. \frac{1}{(x+s)^s} \text{Pf} M_n(x) \right|_{x=-s} \). In order to accomplish this, we apply Lemma 11 with \( N = 2n + 2, a = 2n - 2s, b = 2n, \) and \( A = M_n(x) \). Indeed, \((x+s)\) is a factor of each entry in the \( i \)-th row in matrix \( M_n(x) \), for \( i = 2n - 2s + 1, 2n - 2s + 2, \ldots, 2n \). We obtain

\[
-\left. \frac{1}{(x+s)^s} \text{Pf} M_n(x) \right|_{x=-s} = -\text{Pf}(\tilde{Q}) \text{Pf}(\Sigma), \tag{5.26}\]

where

\[
\tilde{Q} = \left( \begin{array}{cc} \overline{Q} & \overline{H} \\ -\overline{H} & 0 \end{array} \right), \tag{5.27}\]

with \( \overline{Q} \) being given by

\[
\overline{Q} = \left( Q_{i,j} \big|_{x=-s} \right)_{1 \leq i,j \leq 2n-2s},
\]

and \( \overline{H} \) by

\[
\overline{H} = \left( H_{i,j} \big|_{x=-s} \right)_{1 \leq i \leq 2n-2s, 1 \leq j \leq 2},
\]

and where

\[
\Sigma = \left( \left. \left( \frac{1}{x+s} Q_{i+2n-2s,j+2n-2s} \right) \right|_{x=-s} \right)_{1 \leq i,j \leq 2s}.
\]

We point out that (5.26) also holds for \( s = 0 \) once we interpret the Pfaffian of an empty matrix (namely the Pfaffian of \( S \)) as 1. In particular, under that convention, the arguments below can be used for \( 0 \leq s \leq n - k - 1 \), that is, including \( s = 0 \).

We must now compute \( \text{Pf}(\tilde{Q}) \) and \( \text{Pf}(\Sigma) \). We start with the evaluation of \( \text{Pf}(\Sigma) \). It follows from (4.12) that the \((i,j)\)-entry of \( S \) is given by

\[
S_{i,j} = \sum_{l=0}^{i+2n-2s-1} (-1)^{l+j+1} \frac{j-i}{i+2n-2s} \frac{j+2n-2s-1}{i+2n-2s-l-1} \frac{l+j+2n-2s}{l} \cdot \frac{(2n-2s+1)! (l+j)!}{(l+j+2n-2s+1)!}.
\]
If we write this using hypergeometric notation, we obtain the alternative expression

$$S_{i,j} = \frac{(-1)^{j+1}(j-i)i_{i+2n-2s}}{(2n-2s+j+1)! (j)_{i-j+2n-2s+1}} 3F_2 \left[ \begin{array}{c} 1 - i - 2n + 2s, 1 + j + 2n - 2s, 1 - j, 2 + 2n - 2s \\ 1 - i + j, 2 + j + 2n - 2s \\ \end{array} ; 1 \right].$$

Rewrite this expression as the limit

$$S_{i,j} = \lim_{\varepsilon \to 0} \frac{(-1)^{j+1}(j-i)i_{i+2n-2s}}{(2n-2s+j+1)! (j)_{i-j+2n-2s+1}} 3F_2 \left[ \begin{array}{c} 1 - i - 2n + 2s, 1 + j + 2n - 2s, 1 - j, 2 + 2n - 2s \\ 1 - i + j, 2 + \varepsilon + j + 2n - 2s \\ \end{array} ; 1 \right].$$

Now we apply one of Thomae’s $3F_2$-transformation formulas (cf. [3, Ex. 7, p. 98])

$$3F_2 \left[ \begin{array}{c} a, b, c \\ d, e \\ \end{array} ; 1 \right] = \frac{\Gamma(e) \Gamma(d + e - a - b - c)}{\Gamma(e - a) \Gamma(d + e - b - c)} 3F_2 \left[ \begin{array}{c} a, -b + d, -c + d \\ d, -b - c + d + e \\ \end{array} ; 1 \right].$$

Thus, we obtain

$$S_{i,j} = \lim_{\varepsilon \to 0} \frac{(-1)^{j+1} \Gamma(2n-2s+\varepsilon+1) \Gamma(2n-2s+j+\varepsilon+2) (j-i)i_{i+2n-2s}}{\Gamma(\varepsilon - i + 2) \Gamma(4n - 4s + i + j + \varepsilon + 1) (2n - 2s+j+1)! (j)_{i-j+2n-2s+1}} \times 3F_2 \left[ \begin{array}{c} 1 - i - 2n + 2s, -i - 2n + 2s, 1 - i \\ 1 - i + j, 2 + \varepsilon - i \\ \end{array} ; 1 \right],$$

or, in usual sum notation,

$$S_{i,j} = \lim_{\varepsilon \to 0} \sum_{l=0}^{i-1} \frac{(-1)^{j+1} (j-i) \Gamma(2n-2s+\varepsilon+1) \Gamma(2n-2s+j+\varepsilon+2)}{\Gamma(l - i + \varepsilon + 2) \Gamma(4n - 4s + i + j + \varepsilon + 1) (l-1)! (2n - 2s + i + 1)! (j)_{2n-2s+i-l+1}} \frac{(1-i)_{l-i} (l-i+j+1)_{2n-2s+i-l-1} (2n - 2s + i - l)_{l}}{l! (2n - 2s + j + 1)! (j)_{2n-2s+i-j-l+1}}.$$

Because of the term $\Gamma(l - i + \varepsilon + 2)$ in the denominator, in the limit only the summand for $l = i - 1$ does not vanish. After simplification, this leads to

$$S_{i,j} = \frac{(-1)^{j+i} (j-i) (2n-2s+i-1)! (2n-2s+j-1)!}{(4n - 4s + i + j)! (2n - 2s + 1)!}.$$

We must evaluate the Pfaffian

$$\text{Pf}_{1 \leq i,j \leq 2s} (S_{i,j}).$$

By factoring some terms out of rows and columns, we see that

$$\text{Pf}_{1 \leq i,j \leq 2s} (S_{i,j}) = (-1)^s (2n - 2s + 1)!^{-s} \times \left( \prod_{i=1}^{2s} (2n - 2s + i - 1)! \right)^s \text{Pf}_{1 \leq i,j \leq 2s} \left( \frac{j - i}{(4n - 4s + i + j)!} \right).$$
This Pfaffian can be evaluated in closed form by Corollary 10 in the next section. The result is that

$$\text{Pf}(S) = (-1)^s (2n - 2s + 1)!^{-s} \left( \prod_{i=1}^{2s} (2n - 2s + i - 1)! \right) \left( \prod_{i=0}^{s-1} \frac{(2i + 1)!}{(4n - 2s + 2i + 1)!} \right).$$  \hspace{1cm} (5.28)

We finally turn to the evaluation of $\det(\tilde{Q})$. If we compare (5.27) with (4.6), then we see that $\tilde{Q} = M_{n-s}(0)$. Hence, using Lemma 6 with $n$ replaced by $n - s$ and with $x = 0$, we see that $-\text{Pf}(\tilde{Q})$ is equal to $M(F_{n-s,0} \setminus \triangle_2(k))$. (The reader should recall the definitions of the region $F_{n,x}$ and of the triangular hole $\triangle_2(k)$ given in the introduction, see again Figure 4.) Figure 7.a shows a typical example where $n - s = 5$ and $k = 2$. Since this region is degenerate, there are many forced lozenges, see Figure 7.b. The enumeration problem therefore reduces to the problem of determining the number of symmetric lozenge tilings of a hexagon with side lengths $2k, 2k, 2k, 2k, 2k, 2$. This number is given by formula (3.1) with $n = k$ and $x = 1$. If we substitute this in (5.26), together with the evaluation (5.28), then, after some manipulation, we obtain

$$- \left( \frac{1}{(x+s)^s} \text{Pf} M_n(x) \right)_{x=-s} = (-1)^s \left( \frac{4k + 1}{2k} \right) \left( \frac{(2s)!}{(2n - 2s + 1)!} \right) \left( \frac{2^s s!}{2^s s!} \right) \times \left( \prod_{i=1}^{2s} (2n - 2s + i - 1)! \right) \left( \prod_{i=0}^{s-1} \frac{(2i)!}{(4n - 2s + 2i + 1)!} \right).$$
Hence, by inserting this in (5.25), we have

\[
P_n(-s) = (-1)^s \left( \frac{4k + 1}{2k} \right) \frac{(2s)!}{(2n - 2s + 1)!} \frac{2^s s!}{2^s s!} \times \left( \prod_{i=1}^{2s} (2n - 2s + i - 1)! \right) \left( \prod_{i=0}^{s-1} (2n - 2s + 2i + 1)! \right) \times \prod_{\ell=1}^{n-k-1} (-s + \ell)^{\ell} \prod_{\ell=n-k+1}^{n} (-s + \ell)^{-\ell+1} \prod_{\ell=n+1}^{2n-1} (-s + \ell)^{-2n+\ell - \chi(\ell>n+k)+1} \times \prod_{\ell=1}^{n} (-s + \ell + \frac{1}{2})^{-1} (2n-2\ell). \tag{5.29}
\]

This completes the proof of Theorem 4.

6. An auxiliary determinant evaluation, and an auxiliary Pfaffian factorization

Mehta and Wang proved the following determinant evaluation in [27]. (There is a typo in the formula stated in [27, Eq. (7)] in that the binomial coefficient \( \binom{n}{k} \) is missing there.)

**Theorem 7.** For all real numbers \( a, b \) and positive integers \( n \), we have

\[
\begin{align*}
\det_{0 \leq i,j \leq n-1} & \left( (a + j - i) \Gamma(b+i+j) \right) \\
& = \left( \prod_{i=0}^{n-1} i! \Gamma(b+i) \right) \sum_{k=0}^{n} (-1)^{k} \binom{n}{k} \left( (b-a)/2 \right)^{k} \left( (b+a)/2 \right)^{n-k}, \tag{6.1}
\end{align*}
\]

as long as the arguments occurring in the gamma functions avoid their singularities.

The sum on the right-hand side of (6.1) can be alternatively expressed as the coefficient of \( z^n/n! \) in

\[
(1 + z)^{(a-b)/2}(1 - z)^{(-a-b)/2}.
\]

Therefore, in the case \( a = 0 \) we obtain the following simpler determinant evaluation.

**Corollary 8.** For all real numbers \( b \) and positive integers \( n \), we have

\[
\begin{align*}
\det_{0 \leq i,j \leq n-1} & \left( (j - i) \Gamma(b+i+j) \right) = \chi(n \text{ is even}) \left( \prod_{i=0}^{n-1} i! \Gamma(b+i) \right) \frac{n! \left( (b/2)_{n/2} \right)}{(n/2)!},
\end{align*}
\]

as long as the arguments occurring in the gamma functions avoid their singularities. Here, as before, \( \chi(A) = 1 \) if \( A \) is true and \( \chi(A) = 0 \) otherwise.

One can obtain the following slightly (but, for our purposes, essentially) stronger statement. It is stated as Eq. (4) in [27], with the argument how to obtain it hinted at at the bottom of page 231 of [27]. Since, from there, it is not completely obvious how to actually complete the argument, we provide a proof.
Proposition 9. For all real numbers \( b \) and positive even integers \( n \), we have

\[
Pf_{0 \leq i, j \leq n-1} ((j - i) \Gamma(b + i + j)) = \prod_{i=0}^{\frac{n}{2} - 1} (2i + 1)! \Gamma(b + 2i + 1), \tag{6.2}
\]
as long as the arguments occurring in the gamma functions avoid their singularities.

Proof. Since the Pfaffian of a skew-symmetric matrix equals the square root of its determinant (cf. (4.3)), the formula given by Theorem 8 yields, after a little manipulation, that

\[
Pf_{0 \leq i, j \leq n-1} ((j - i) \Gamma(b + i + j)) = \varepsilon \prod_{i=0}^{\frac{n}{2} - 1} (2i + 1)! \Gamma(b + 2i + 1), \tag{6.3}
\]
where \( \varepsilon = +1 \) or \( \varepsilon = -1 \). In order to determine the sign \( \varepsilon \), we argue by induction on (even) \( n \). Let us suppose that we have already proved (6.2) up to \( n - 2 \). We now multiply both sides of (6.3) by \( b + 1 \) and then let \( b \) tend to \(-1\). Thus, on the right-hand side we obtain the expression

\[
\varepsilon \left( \prod_{i=0}^{\frac{n}{2} - 1} (2i + 1)! \right) \left( \prod_{i=1}^{\frac{n}{2} - 1} \Gamma(2i) \right). \tag{6.4}
\]

On the other hand, by the definition of the Pfaffian, on the left-hand side we obtain

\[
\sum_{\pi \in \mathcal{M}[0, \ldots, n-1]} \text{sgn} \pi \lim_{b \to -1} \left( (b + 1) \prod_{i,j \text{ matched in } \pi} (j - i) \Gamma(b + i + j) \right) \tag{6.5}
\]
(with the obvious meaning of \( \mathcal{M}[0, \ldots, n-1] \); cf. the sentence containing (4.2)). In this sum, matchings \( \pi \) for which all matched pairs \( i, j \) satisfy \( i + j > 1 \) do not contribute, because the corresponding summands vanish. However, there is only one possible pair \( i, j \) with \( 0 \leq i < j \) for which \( i + j \leq 1 \), namely \( (i, j) = (0, 1) \). Therefore, the sum in (6.5) reduces to

\[
\sum_{\pi' \in \mathcal{M}[2, \ldots, n-1]} \text{sgn} \pi' \left( \lim_{b \to -1} (b + 1)(1 - 0) \Gamma(b + 1) \right) \prod_{i,j \text{ matched in } \pi'} (j - i) \Gamma(i + j - 1)
\]

\[= Pf_{2 \leq i, j \leq n-1} ((j - i) \Gamma(i + j - 1)) \]
\[= Pf_{0 \leq i, j \leq n-3} ((j - i) \Gamma(i + j + 3)), \]
where the next-to-last equality holds by the definition (4.2) of the Pfaffian. Now we can use the induction hypothesis to evaluate the last Pfaffian. Comparison with (6.4) yields that \( \varepsilon = +1 \). \( \Box \)

By using the reflection formula (cf. [2, Theorem 1.2.1])

\[
\Gamma(x) \Gamma(1 - x) = \frac{\pi}{\sin \pi x}
\]
for the gamma function, and the substitutions \( i \to n - i - 1 \) and \( j \to n - j - 1 \), it is not difficult to see that Proposition 9 is equivalent to the following.
Corollary 10. For all positive even integers \(n\), we have
\[
\operatorname{Pf}_{0 \leq i, j \leq n-1} \left( \frac{j - i}{\Gamma(b + i + j)} \right) = \prod_{i=0}^{n-1} \frac{(2i + 1)!}{\Gamma(b + n + 2i - 1)}.
\]

We close this section by proving a factorization of a certain specialization of a Pfaffian that we need in Step 5 in Section 5.

Lemma 11. Let \(N, a, b\) be positive integers with \(a < b \leq N\), where \(N\) and \(b - a\) are even. Let \(A = (A_{i,j})_{1 \leq i, j \leq N}\) be a skew-symmetric matrix with the following properties:
1. The entries of \(A\) are polynomials in \(x\).
2. The entries in rows \(a+1, a+2, \ldots, b\) (and, hence, also in the corresponding columns) are divisible by \(x + s\).

Then
\[
\left. \left( \frac{1}{(x + s)^{(b-a)/2}} \operatorname{Pf} A \right) \right|_{x = -s} = \operatorname{Pf} \tilde{A} \cdot \operatorname{Pf} S,
\]
where \(\tilde{A}\) is the matrix which arises from \(A\) by deleting rows and columns \(a+1, a+2, \ldots, b\) and subsequently specializing \(x = -s\), and
\[
S = \left( \left. \left( \frac{1}{x + s} A_{i,j} \right) \right|_{x = -s} \right)_{a+1 \leq i, j \leq b}.
\]

Proof. By the definition (4.2) of the Pfaffian, we have
\[
\left. \left( \frac{1}{(x + s)^{(b-a)/2}} \operatorname{Pf} A \right) \right|_{x = -s} = \left. \left( \frac{1}{(x + s)^{(b-a)/2}} \sum_{\pi \in \mathcal{M}[1, \ldots, N]} \operatorname{sgn} \pi \prod_{i < j} A_{i,j} \right) \right|_{x = -s}.
\]

Let \(\mathcal{M}_1\) denote the subset of \(\mathcal{M}[1, \ldots, N]\) consisting of those matchings that pair all the elements from \(\{a + 1, a + 2, \ldots, b\}\) among themselves (and, hence, all the elements of the complement \(\{1, 2, \ldots, a, b+1, b+2, \ldots, N\}\) among themselves). Let \(\mathcal{M}_2\) be the complement \(\mathcal{M}[1, \ldots, N] \setminus \mathcal{M}_1\). Then
\[
\left. \left( \frac{1}{(x + s)^{(b-a)/2}} \operatorname{Pf} A \right) \right|_{x = -s} = \left. \left( \frac{1}{(x + s)^{(b-a)/2}} \sum_{\pi \in \mathcal{M}_1} \operatorname{sgn} \pi \prod_{i < j} A_{i,j} \right) \right|_{x = -s} + \left. \left( \frac{1}{(x + s)^{(b-a)/2}} \sum_{\pi \in \mathcal{M}_2} \operatorname{sgn} \pi \prod_{i < j} A_{i,j} \right) \right|_{x = -s}.
\]

Each term in the sum in the second line of (6.7) vanishes, since the product contains more than \((b - a)/2\) factors \(A_{i,j}\) that are divisible by \(x + s\). On the other hand, every matching
\( \pi \) in \( \mathcal{M}_1 \) is the disjoint union of a matching \( \pi' \in M[1, 2, \ldots, a, b+1, b+2, \ldots, N] \) and a matching \( \pi'' \in M[a+1, a+2, \ldots, b] \). If we also use the simple fact that \( \text{sgn } \pi = \text{sgn } \pi' \cdot \text{sgn } \pi'' \) (as there are no crossings between paired elements of \( \pi' \) and paired elements of \( \pi'' \)), then we obtain

\[
\left. \left( \frac{1}{(x+s)^{(b-a)/2}} \text{Pf } A \right) \right|_{x=-s} = \left. \left( \frac{1}{(x+s)^{(b-a)/2}} \sum_{\pi' \in M[1, \ldots, a,b+1, \ldots, N]} \sum_{\pi'' \in M[a+1, \ldots, b]} \text{sgn } \pi' \cdot \text{sgn } \pi'' \right) \cdot \left( \prod_{i<j} A_{i,j} \right) \right|_{x=-s}.
\]

By the definition (4.2) of the Pfaffian, the last expression is exactly the right-hand side of (6.6). \( \square \)

7. Proofs of Theorems 1 and 2

In our proofs we make use of the following lemmas.

Lemma 12. Let \( \beta \) be a real number with either \( \beta > 0 \) or \( \beta < -1 \). Then, for all sequences \( (\beta_n)_{n \geq 1} \) with \( \beta_n \to \beta \) as \( n \to \infty \), we have

\[
\lim_{n \to \infty} \frac{1}{\sqrt{n}} \binom{5}{-2n, \frac{1}{2}, -n+k+1, -n+k+1, \beta_n n + 1}{-2n+\frac{1}{2}, -n-k, -n-k, \beta_n n + 1, 1} = \int_{0}^{1} \frac{\sqrt{2} (1-\alpha)^{4k+2}}{(1+\frac{\alpha}{\beta}) \sqrt{\pi \alpha (2-\alpha)}} d\alpha,
\]

where, on the left-hand side, we used again the standard notation (5.22) for hypergeometric series.

Proof. We write the \( \binom{5}{\cdot} \)-series in (7.1) explicitly as a sum over \( l \):

\[
\sum_{l=0}^{n-k-1} \frac{\Gamma(2n+1) \Gamma(l+\frac{1}{2}) \Gamma(2n-l+\frac{1}{2}) \Gamma(n-k)^2 \Gamma(n+k-l+1)^2}{\Gamma(2n-l+1) \Gamma(l+1) \Gamma(2n+\frac{1}{2}) \Gamma(n-k-l)^2 \Gamma(n+k+1)^2} \frac{\beta_n n}{(\beta_n n + l)}.
\]
Let us denote the summand in this sum by $F(n, l)$. We have
\[
\frac{\partial}{\partial l} F(n, l) = F(n, l) \left( \psi(l + \frac{1}{2}) - \psi(l + 1) + \psi(2n - l + 1) - \psi(2n - l + \frac{1}{2}) \\
+ 2\psi(n - k - l) - 2\psi(n + k - l + 1) - \frac{1}{\beta_n n + l} \right),
\]
where $\psi(x) := (\frac{d}{dx} \Gamma(x))/\Gamma(x)$ is the digamma function. Since $\psi(x)$ is a monotone increasing, concave function for $x > 0$ (this follows e.g. from [2, Eq. (1.2.14)]), we have
\[
\psi(l + 1) - \psi(l + \frac{1}{2}) \geq \psi(2n - l + 1) - \psi(2n - l + \frac{1}{2})
\]
for $0 \leq l \leq n$. Moreover, because of the equality $\psi(x + 1) = \psi(x) + \frac{1}{x}$ (cf. [2, Eq. (1.2.15) with $n = 1$]), and since either $\beta > 0$ or $\beta < -1$, for large enough $n$ we have
\[
\psi(n + k - l + 1) \geq \psi(n - k - l) + \frac{1}{n + k - l} > \psi(n - k - l) - \frac{1}{\beta_n n + l}.
\]
Altogether, this implies that $\frac{\partial}{\partial l} F(n, l) < 0$ for $0 \leq l \leq n - k - 1$, that is, for fixed large enough $n$, the summand $F(n, l)$ is monotone decreasing as a function in $l$. In particular, for $0 \leq l \leq n - k - 1$ we have
\[
0 < F(n, l) \leq F(n, 0) = 1.
\]
(7.8)
The sum (7.7) may therefore be approximated by an integral:
\[
\sum_{l=0}^{n-k-1} F(n, l) = \sum_{l=0}^{\lfloor \log n \rfloor - 1} F(n, l) + \sum_{l=\lfloor \log n \rfloor}^{n-k-\lfloor \log n \rfloor - 1} F(n, l) + \sum_{l=n-k-\lfloor \log n \rfloor}^{n-k-1} F(n, l)
= O(\log n) + \int_{\lfloor \log n \rfloor - 1}^{n-k-\lfloor \log n \rfloor - 1} F(n, l) \, dl.
\]
(7.9)
The next step is to apply Stirling’s approximation
\[
\log \Gamma(z) = \left( z - \frac{1}{2} \right) \log(z) - z + \frac{1}{2} \log(2\pi) + O \left( \frac{1}{z} \right)
\]
for the gamma function, in the form
\[
\log \Gamma(an + bl + c) = \left( an + bl + c - \frac{1}{2} \right) \left( \log \left( a + b\frac{l}{n} \right) + \log(n) + \log \left( 1 + \frac{c}{an+bl} \right) \right)
- (an + bl + c) + \frac{1}{2} \log(2\pi) + O \left( \frac{1}{an+bl} \right)
= \left( an + bl + c - \frac{1}{2} \right) \left( \log(a + b\frac{l}{n}) + \log(n) \right)
- (an + bl) + \frac{1}{2} \log(2\pi) + O \left( \frac{1}{an+bl} \right),
\]
where $a, b, c$ are real numbers with $a \geq 0$. If this is used in the defining expression for $F(n, l)$, then after cancellations we obtain

$$
\log F(n, l) = \frac{1}{2} \log(2) + (4k + 2) \log \left(1 - \frac{l}{n}\right) - \frac{1}{2} \log \left(2 - \frac{l}{n}\right) - \frac{1}{2} \log \left(\frac{n}{\beta_n n}\right)
$$

$$
- \frac{1}{2} \log \left(\frac{l}{n}\right) - \frac{1}{2} \log(n) - \frac{1}{2} \log(\pi) - \log \left(1 + \frac{l}{\beta_n n}\right)
$$

$$
+ O\left(\frac{1}{l}\right) + O\left(\frac{1}{n - l}\right) + O\left(\frac{1}{2n - l}\right) + O\left(\frac{1}{n}\right)
$$

$$
= \log \left(\frac{\sqrt{2} (1 - \frac{l}{n})^{4k+2}}{\sqrt{n}\sqrt{1 + \frac{l}{\beta_n n}} \sqrt{\pi\frac{1}{n} (2 - \frac{l}{n})}}\right) + O\left(\frac{1}{\log n}\right)
$$

as long as $\log n \leq l \leq n - k - \log n$. Substitution of this approximation in (7.9) yields

$$
\sum_{l=0}^{n-k-1} F(n, l)
$$

$$
= \left(\int_{[\log n] - 1}^{n-k-[\log n]-1} \frac{\sqrt{2} (1 - \frac{l}{n})^{4k+2}}{\sqrt{n}(1 + \frac{l}{\beta_n n}) \sqrt{\pi\frac{1}{n} (2 - \frac{l}{n})}} dl\right) \left(1 + O\left(\frac{1}{\log n}\right)\right) + O\left(\log n\right),
$$

or, after the substitution $l = \alpha n$,

$$
\sum_{l=0}^{n-k-1} F(n, l)
$$

$$
= \sqrt{n} \int_{([\log n] - 1)/n}^{(n-k-[\log n]-1)/n} \frac{\sqrt{2} (1 - \alpha)^{4k+2}}{(1 + \frac{\alpha}{\beta_n \alpha}) \sqrt{\pi\alpha (2 - \alpha)}} d\alpha \left(1 + O\left(\frac{1}{\log n}\right)\right) + O\left(\log n\right).
$$

The assertion of the lemma follows now immediately. □

With no extra work we can now get an exact formula for a generalization $\omega_f(k; \xi)$ of the correlation $\omega_f(k)$ described in Section 2. For any real number $\xi > 0$, define $\omega_f(k; \xi)$ in analogy to (2.1) by

$$
\omega_f(k; \xi) := \lim_{n \to \infty} \frac{M(F_n, \xi_n n) \setminus \vartriangle_2(k)}{M(F_n, \xi_n n)},
$$

(7.11)

where $(\xi_n)_{n \geq 1}$ is a suitable sequence of rational numbers approaching $\xi$. ("Suitable" here means that we have to choose $\xi_n$ in such a way that $\xi_n n$ is integral.) The number $\omega_f(k; \xi)$ is the correlation of the triangular gap $\vartriangle_2(k)$ with the free boundary, obtained when the large regions used in the definition are the left halves of hexagons that are not necessarily regular, but have their left vertical side $\xi$ times as long as the two oblique sides. Note that, by the results of [9], we should expect distorted dimer statistics around the gap for $\xi \neq 1$. As Theorem 15 shows, the distortion is quite radical: $\omega_f(k; \xi)$ turns out to decay exponentially to 0 or blow up exponentially, according as $\xi > 1$ or $\xi < 1$; see also Remark 1.
Lemma 13. For any $\xi > 0$ and $0 \leq k \in \mathbb{Z}$, we have

$$\omega_f(k; \xi) = \frac{1}{\pi} \left(\frac{4k+1}{2k}\right) \frac{1}{(1+\xi)^{4k+2}/\sqrt{2+\xi}} \times \left( (\xi+2) \int_0^1 \frac{(1-\alpha)^{4k+2}}{(1+\frac{\alpha}{\xi})\sqrt{\alpha(2-\alpha)}} \, d\alpha - \xi \int_0^1 \frac{(1-\alpha)^{4k+2}}{(1-\frac{\alpha}{2+\xi})\sqrt{\alpha(2-\alpha)}} \, d\alpha \right)$$

$$= \frac{1}{\pi} \left(\frac{4k+1}{2k}\right) \frac{1}{(1+\xi)^{4k+2}/\sqrt{2+\xi}} \int_0^1 \frac{2(1-\alpha)^{4k+3}}{(1-\frac{\alpha}{2+\xi})(1-\frac{\alpha}{2+\xi})\sqrt{\alpha(2-\alpha)}} \, d\alpha. \quad (7.12)$$

Proof. By Theorem 4 and formula (3.1), the ratio between $M(F_{n,x} \setminus \mathcal{A}_2(k))$ and $M(F_{n,x})$ is, when written in hypergeometric notation,

$$\frac{1}{2} \frac{(4k+1)}{2k} \frac{(n+k)!}{(n-k+1)_{2k+1}} \frac{(x+1)_{n-k-1}}{(n+k+1)_{n-k}} \frac{(x+n+k+1)}{(n-k-1)! (n+k+1)_{n-k}} \times \left( (x+2n) \binom{4}{2} F_4 \left[ \begin{array}{c} -2n+\frac{1}{2}, -n+k+1, -n+k+1, x \\ -2n+\frac{1}{2}, -n-k, -n-k, x+1 \end{array} ; 1 \right] \right) - x \binom{4}{2} F_4 \left[ \begin{array}{c} -2n+\frac{1}{2}, -n+k+1, -n+k+1, -2n-x \\ -2n+\frac{1}{2}, -n-k, -n-k, -2n-x+1 \end{array} ; 1 \right].$$

We now substitute $x = \xi_n k$ in this expression. Use of Lemma 12 (which applies, as $\xi > 0$), together with Stirling’s formula (7.10), yields the assertion. □

Lemma 14. For any $\beta \neq 0$ we have

$$\int_0^1 \frac{(1-\alpha)^{4k+2}}{(1+\frac{\alpha}{\xi})\sqrt{\alpha(2-\alpha)}} \, d\alpha \sim \sqrt{\frac{\pi}{8k}}, \quad k \to \infty. \quad (7.13)$$

Proof. Let $I_\beta(k)$ be the integral on the left hand side of (7.13). The asymptotics of $I_\beta(k)$ as $k \to \infty$ can be readily found using Laplace’s method as presented for instance in [28]. Conditions (i)-(v) of [28, pp. 121–122] are readily checked. By [28, Theorem 6.1, p. 125], the large $z$ asymptotics of $\int_a^b e^{-pz(t)} q(t) \, dt$ is determined by the quantities $\lambda$, $\mu$, $p_0$ and $q_0$ in the series expansions

$$p(t) - p(a) = p_0(t-a)^\mu + p_1(t-a)^{\mu+1} + \cdots$$

and

$$q(t) = q_0(t-a)^\lambda + q_1(t-a)^{\lambda+1} + \cdots.$$ 

Namely, under the above assumptions one has

$$e^{zp_0/a} \int_a^b e^{-pz(t)} q(t) \, dt = \Gamma \left( \frac{\lambda}{\mu} \right) \frac{q_0/(\mu p_0^{\lambda/\mu})}{z^{\lambda/\mu}} + O \left( \frac{1}{z^{\lambda/\mu+1}} \right). \quad (7.14)$$

In the case of $I_\beta(k)$ we have $p(t) = -\ln(1-t)$, $q(t) = 1/((1-t/\beta)(2-t/\beta))$, $a = 0$, and $b = 1$. These yield parameters $\lambda = 1/2$, $\mu = 1$, $p_0 = 1$, and $q_0 = 1/\sqrt{2}$. In addition, $p(a) = 0$. As in our case $z = 4k+2$, under these specializations (7.14) becomes (7.13). □
**Theorem 15.** As \( k \to \infty \), the correlation \( \omega_f(k; \xi) \) is asymptotically

\[
\omega_f(k; \xi) \sim \frac{1}{\pi (1 + \xi)^2 \sqrt{\xi(2 + \xi)}} \cdot \frac{1}{k} \left( \frac{2}{1 + \xi} \right)^{4k}.
\]

**Proof.** Combine Lemmas 13 and 14 with Stirling’s approximation for the binomial coefficient \( \binom{4k+1}{2k} \) in (7.12). \( \square \)

**Proof of Theorem 1.** Set \( \xi = 1 \) in Theorem 15. \( \square \)

**Proof of Theorem 2.** Set

\[
D_k := 3I_1(k) - I_{-3}(k),
\]

where \( I_\beta(k) \) denotes the integral on the left hand side of (7.13). Recalling that \( \omega_f(k) \) is the \( \xi = 1 \) specialization of \( \omega_f(k; \xi) \), we have by Lemma 13 that

\[
\omega_f(k+1) - \omega_f(k) = \frac{1}{\pi} \frac{1}{2^{4k+2} \sqrt{3}} \left( \frac{4k+1}{2k} \right) \left\{ \left[ \frac{(4k+3)(4k+5)}{4(2k+2)(2k+3)} - 1 \right] D_{k+1} + (D_{k+1} - D_k) \right\},
\]

and thus

\[
\frac{\omega_f(k+1) - \omega_f(k)}{\omega_f(k)} = \left[ \frac{(4k+3)(4k+5)}{4(2k+2)(2k+3)} - 1 \right] \frac{D_{k+1}}{D_k} + \frac{D_{k+1} - D_k}{D_k}.
\] (7.15)

By two applications of Lemma 14 it follows that

\[
D_k \sim \frac{\sqrt{\pi}}{\sqrt{2k}}, \quad k \to \infty.
\] (7.16)

Thus \( D_{k+1}/D_k \to 1 \) as \( k \to \infty \), and elementary arithmetics implies that the first term on the right hand side of (7.15) is asymptotically \(-1/(2k)\) as \( k \to \infty \).

To determine the asymptotics of the second term, write by Lemma 13

\[
D_{k+1} - D_k = 3 \left[ I_1(k+1) - I_1(k) \right] - \left[ I_{-3}(k+1) - I_{-3}(k) \right].
\] (7.17)

As \( I_\beta(k) \) is the integral on the left hand side of (7.13), we have

\[
I_\beta(k+1) - I_\beta(k) = \int_0^1 \frac{(1 - \alpha)^{4k+2}}{\left( 1 + \frac{4}{3} \right) \sqrt{\alpha(2 - \alpha)}} \left[ (1 - \alpha)^4 - 1 \right] d\alpha.
\] (7.18)

The asymptotics of the integral in (7.18) follows by Laplace’s method, in the same manner as the proof of Lemma 14. In this case \( \lambda = 3/2, \mu = 1 \), and equations (7.14) and (7.18) imply that

\[
I_\beta(k+1) - I_\beta(k) \sim \frac{\sqrt{\pi}}{4\sqrt{2k^{3/2}}}, \quad k \to \infty.
\] (7.19)

Equations (7.17) and (7.19) determine the asymptotics of \( D_{k+1} - D_k \), and combining this with the asymptotics of \( D_k \) given by (7.16) we obtain that the second term on the right hand side of (7.15) has asymptotics \(-1/(2k)\) as \( k \to \infty \). The two terms on the right hand side of (7.15) thus have a sum that is asymptotically \(-1/(2k) - 1/(2k) = -1/k\), and Theorem 2 is proved. \( \square \)
