Aim: To investigate the mechanism of chlorogenic acid (CA)-induced anaphylactoid reactions.

Methods: Degranulation of peritoneal mast cells was assayed by using alcian blue staining in guinea pigs, and the degranulation index (DI) was calculated. CA-induced degranulation of RBL-2H3 cells was also observed and assayed using light microscopy, transmission electron microscopy, flow cytometry, and β-hexosaminidase release.

Results: CA 0.2, 1.0, and 5.0 mmol/L was able to promote degranulation of peritoneal mast cells in guinea pigs in vitro, but it did not increase the degranulation of peritoneal mast cells in CA-sensitized guinea pigs compared with control (P>0.05). Treatment with CA 0.2, 1.0, and 5.0 mmol/L for 30, 60, and 120 min induced degranulation in RBL-2H3 cells in a dose- and time-dependent manner (P<0.01). Under transmission electron microscope typical characteristics of degranulation, including migration of granular vesicles toward the plasma membrane and integration combined with exocytosis, were observed, after CA or C48/80 treatment. Fluorescent microscopy and flow cytometric analysis showed that CA induced concentration-dependent translocation of phosphatidylserine in RBL-2H3 cells. β-hexosaminidase release in RBL-2H3 cells was significantly increased after incubation with 1 mmol/L CA for 60 min and 5 mmol/L CA for 30 min (P<0.01).

Conclusion: CA induces degranulation of peritoneal mast cells and RBL-2H3 cells in guinea pigs, which might be one of the mechanisms of the generation of anaphylactoid reactions induced by CA.

Acta Pharmacologica Sinica (2010) 31: 849–854; doi: 10.1038/aps.2010.63; published online 28 June 2010
acclimation period of at least 10 days. All experiments were carried out according to the guidelines of China for the care and use of laboratory animals.

**Cells**

RBL-2H3 cells were obtained from the cell bank of the Chinese Academy of Sciences. Cells were cultured in Dulbecco’s modified Eagle’s medium (Gibco, Grand Island, USA) containing 10% heat-inactivated fetal bovine serum and 40 U/mL gentamicin in a humidified atmosphere of 5% CO₂ at 37 °C.

**Reagents**

A CA standard (in vitro test) was purchased from the National Institute for the Control of Pharmaceutical and Biological Products (Beijing, China). CA (in vivo test, >98%) was purchased from Guanghan Biological Products Co, Ltd (Sichuan, China). Compound 48/80 (C48/80) was purchased from Sigma (St Louis, USA). Trypsin was purchased from Gibco (Grand Island, USA). The annexin-V Fluos staining kit was purchased from Roche (Indianapolis, USA). Percoll and p-nitrophenyl-N-acetyl-β-D-glucosaminide were also purchased from Sigma (St Louis, USA). Alcian blue was purchased from Edward Gurr (London, UK).

**Alcian blue staining and degranulation index (DI) calculation of guinea pig peritoneal mast cells**

Guinea pigs were first pre-sensitized with 2% CA (0.5 mL CA, ip, once every two days for ten days) and, ten days after the last pre-sensitization, peritoneal mast cells were collected. Mast cells were also collected from normal (non-sensitized) guinea pigs as a control. Both control and pre-sensitized guinea pigs were then injected ip with 10 mL calcium-free Tyrode’s solution (4 °C) after the animals were killed by exsanguination under general anesthesia. After kneading the abdomen clockwise for 3–5 min, 5 mL of ascites fluid was collected and added to 30%/80% Percoll gradient centrifugation tubes and centrifuged at 2500 r/min for 15 min. All cells were washed twice in Tyrode’s solution and then transferred to culture tubes after adjusting the cell density. The cells (3.7×10⁵–5.2×10⁵/mL) in each tube were treated with different concentrations of CA (0.2, 1.0, or 5.0 mmol/L) and stained with alcyan blue after 30 min of incubation at 37 °C. Basophils were counted by microscopy, and the DI was calculated relative to negative control tubes. The percentage of degranulation was calculated using the following formula:

\[
\text{DI} = \frac{(\text{number of stained cells in control tube} - \text{number of stained cells in CA treated tube}) \times 100}{\text{number of stained cells in control tube}}
\]

**Evaluation of RBL-2H3 cell exposure to CA**

**Light microscopic observation**

RBL-2H3 cells in the exponential growth phase were incubated with different concentrations of CA (0.2, 1.0, or 5.0 mmol/L) and C48/80 (30 μg/mL), which was used as a positive control, for 30, 60, and 120 min at 37 °C. The reaction was terminated by incubating the tubes in an ice bath for 10 min. Cells were then stained with alcyan blue for 10 min (a final concentration of 1.0×10⁶ cells/mL was in each tube). A basophil count was performed, and the DI was calculated. Stained cell images were captured using a Motic AE30 EF-INV-III Inverted Fluorescence Microscope.

**Transmission electron microscopic observation**

For transmission electron microscopy, RBL-2H3 cells were treated with CA (0.2, 1.0, or 5.0 mmol/L) and C48/80 for 1 h. Then, the cells were fixed in glutaraldehyde-formaldehyde followed by osmium tetroxide, stained en bloc with uranyl acetate, embedded in Araldite and examined with a Hitachi (Tokyo, Japan) 600A electron microscope at 75 kV.

**Fluorescent microscopic observation**

According to the instructions provided with the annexin-V Fluos staining kit, RBL-2H3 cells, which had been treated with different concentrations of CA, were harvested, washed twice with cold PBS and resuspended in binding buffer containing FITC-conjugated annexin-V (5 μL). After 15 min in the dark, cells were mounted on a slide, examined under an Olympus fluorescent microscope and photographed using Kodak Elite II 100 slide film (Eastman Kodak, Rochester, NY).

**Flow cytometric analysis**

Cells were treated as discussed above. After 15 min in the dark with annexin-V, cells were analyzed with a FACScan flow cytometer (Becton Dickinson, San Jose, CA, USA).

**β-Hexosaminidase release**

RBL-2H3 cells (2×10⁵/well) in 24-well plates were washed with PIPES buffered solution. The cells were stimulated by different concentrations of CA at 37 °C under gentle rotation. The supernatants were collected and transferred to a 96-well plate. Subsequently, Triton X-100 solution (0.5%) was added to the cells to quantify the remaining enzyme activity. The extracts were transferred to another 96-well plate. The absorbance at 405 nm (OD) of each well was measured. The percentage of degranulation was calculated using the following formula:

\[
\% \text{β-hexosaminidase release} = \frac{OD_{\text{supernatant}}}{OD_{\text{supernatant} + OD_{\text{Triton X-100}}}} 	imes 100
\]

**Statistical analysis**

All values are reported as means±standard deviation (SD). Statistical significance was analyzed using the Student’s unpaired t-test. Values of *P*<0.05 were considered statistically significant.

**Results**

**CA-induced degranulation in guinea pig peritoneal mast cells**

As shown in Table 1, CA promoted the degranulation of guinea pig peritoneal mast cells in vitro but did not increase the peritoneal mast cell DI in CA-sensitized guinea pigs. These results suggest that CA may cause anaphylactoid reactions rather than anaphylactic reactions.
CA-induced degranulation in RBL-2H3 cells

**Cell morphological changes**

RBL-2H3 cells were adherent in monolayer, and a high degree of intracytoplasmic heterogeneity among particles could be observed with the inverted phase contrast microscope. RBL-2H3 cells appeared round with non-staining nuclei, and were evenly distributed within the light blue particulate after staining with alcian blue. After degranulation, RBL-2H3 cells showed deformation to vary degrees, including sparse intracellular particles, and even vacuolated cytoplasms and faded color. DI was calculated according to the formula shown above by counting the degranulated cells in the visual range after unifying the observation standards and adjusting cell concentrations; results are shown in Table 2. Our results demonstrate that CA can cause RBL-2H3 cell degranulation in a dose- and time-dependent manner.

**Ultrastructural changes**

Using transmission electron microscopy, we found clear nucleoli, cell membranes with many microvilli, cytoplasmic bubble-like particles of different sizes and some intracellular small dense particles in RBL-2H3 cells (culture) (Figure 1A). In cells treated with CA and C48/80, we observed chromatin condensation, dilatation of the endoplasmic reticulum, a decrease in intracellular particulates, sparse cytoplasm and a considerable increase in the number of vesicles and vacuole-like structures. Furthermore, typical characteristics of degranulation, including migration of granular vesicles toward the plasma membrane and integration combined with exocytosis, were observed (Figure 1B–1E). With increased CA concentration, increases in intracellular vacuole-like structures and degranulation effects were seen (Figure 1C–1E).

**Fluorescent microscopy observation**

As shown in Figure 2, in the low CA (0.2 mmol/L) group, only a few cells showed positive staining. As the CA concentration increased, the ratio of positive staining was markedly increased. The majority of cells in the high CA (5.0 mmol/L) group showed positive staining. Thus, CA can induce the concentration-dependent translocation of phosphatidylserine in RBL-2H3 cells.

**Flow cytometric analysis**

The positive staining ratio increased when the CA concentration was increased (Figure 3). This funding suggests that CA could induce the concentration-dependent translocation of phosphatidylserine in RBL-2H3 cells.

**β-Hexosaminidase release**

As shown in Table 3, there was no increase in β-hexosaminidase release in RBL-2H3 cells after incubation with a low concentration of CA (0.2 mmol/L) for 120 min. However, β-hexosaminidase release in RBL-2H3 cells significantly increased after incubation with 1 mmol/L CA for 60 min and 5 mmol/L CA for 30 min. β-Hexosaminidase release was associated with the concentration of CA and the incubation time. This correlation provided indirect proof that CA can induce the degranulation of RBL-2H3 cells.

### Table 1. The effect of CA to the degranulation of guinea pig’s peritoneal mast cells. n=3. Mean±SD. *P>0.05 vs Normal, t-test.

| Concentration (mmol/L) | Normol DI (%) | Sensitized DI (%) |
|------------------------|---------------|------------------|
| 0.2                    | 15.6±12.3     | 13.2±6.8*        |
| 1.0                    | 27.4±6.9      | 26.9±8.7*        |
| 5.0                    | 36.2±9.2      | 35.8±7.9*        |

### Table 2. The effect of CA to the ratio of degranulation of RBL-2H3 cell. n=5. Mean±SD. bP<0.05, cP<0.01 vs Control, t-test.

| Concentration | Ratio of degranulation at different times (%) | 30 min | 60 min | 120 min |
|---------------|-----------------------------------------------|--------|--------|---------|
| Control –     | 6.4±1.61                                      | 5.93±3.25 | 5.85±2.23 |
| CA 0.2 mmol/L | 12.39±5.03*                                  | 15.84±4.52* | 19.13±6.04* |
| CA 1.0 mmol/L | 15.85±4.31*                                  | 23.57±4.63* | 33.02±9.92* |
| CA 5.0 mmol/L | 23.08±7.88*                                  | 35.83±5.07* | 42.43±3.84* |
| C48/80 30 μg/mL | 12.14±4.32*                                    | 19.29±5.01* | 33.57±4.62* |

Discussion

Anaphylaxis and anaphylactoid reactions are clinically indistinguishable but differ in their pathogenic mechanisms. Anaphylaxis is a type I, or immediate, hypersensitivity reaction to an allergen. In this type of reaction, antigen-specific IgE binds to mast cells and basophils and is cross-linked by allergen, which triggers the release of preformed chemical mediators, such as histamine and tryptase, and then results in the multi-organ symptoms of anaphylaxis [5, 6]. Unlike anaphylactic reactions, anaphylactoid reactions are not dependent on drug-specific IgE and do not necessarily require previous exposure to an inciting substance. Many pathways can induce anaphylactoid reactions. Drugs can stimulate mast cells and basophils to release biologically active substances via physical or chemical mechanisms that are non-immune; alternatively, drugs can stimulate cells to release biologically active substances via complement activation (one of the mechanisms of the immune system) or other pathways [7].

Anaphylaxis and anaphylactoid reactions have complex compositions and a large number of excipients. Anaphylactoid reactions may occur if the injections are deliv-
RBL-2H3 cells have been extensively β-chloroethylamine using the limited dilution technique, from leukemic cells iso-
reactions. The continuous rat cell line, RBL-2H3, was cloned, a key element in the study of anaphylaxis and anaphylactoid
Therefore, the degranulation of mast cells and basophils is a mechanism: the degranulation of mast cells or basophils.
pre-sensitization. This result serves as further evidence that the effect of degranulation induced by CA is not related
to sensitization and that the anaphylactoid symptoms (eg, trembling, salivation, tears and vomiting) could be observed
during the first injection of CA in Beagle dogs (results not shown in this paper). In the present study, we find that CA can promote the degranulation of guinea pig peritoneal mast cells, but it does not increase the peritoneal mast cell DI in CA-sensitized guinea pigs. Our findings indicate that the effect of degranulation induced by CA is not related to pre-sensitization. This result serves as further evidence that CA can cause anaphylactoid reactions.
Anaphylaxis and anaphylactoid reactions share a common mechanism: the degranulation of mast cells or basophils. Therefore, the degranulation of mast cells and basophils is a key element in the study of anaphylaxis and anaphylactoid reactions. The continuous rat cell line, RBL-2H3, was cloned, using the limited dilution technique, from leukemic cells isolated from rats after treatment with the chemical carcinogen β-chloroethylamine. RBL-2H3 cells have been extensively used for studying IgE–FcεRI interactions, for studying signaling pathways of degranulation and for testing novel mast cell stabilizers. An advantage of using the RBL-2H3 cell line is that a great number of monoclonal cells can be rapidly obtained by simple cell culture techniques; therefore, it is a useful tool for in vitro study.
Traditional methods of quantitatively measuring mast cell degranulation include calculating the DI (ie, direct observation and counting of cells stained with alcian blue) and observing the histamine release rate (ie, determination of histamine levels by ELISA or fluorospectrophotometry). However, ELISA sensitivity is too low to be useful in microanalysis because of the short half-life of histamine and instability of the fluorescent material. In recent years, the rates of β-hexosaminidase release and annexin-V positive cells have gradually become the preferred indices in degranulation research. β-Hexosaminidase is one of the many acid hydrolases present in mast cell granules and released from the cell membrane. Annexin-V is calcium-dependent and binds to phosphatidyserines exposed on the plasma membrane during apoptosis. With mast cell activation, exogenous annexin-V binds to secretory granules on the cell surface in proportion to the degree of degranulation, as measured by β-hexosaminidase release.
In this study, we demonstrated the direct induction of degranulation by CA in rat RBL-2H3 cells and investigated the cellular mechanisms of CA-induced anaphylactoid reactions. Our results showed that CA is able to induce degranulation in RBL-2H3 cells. Furthermore, dose-dependent and time-dependent translocation of phosphati-
dyserine and release of β-hexosaminidase were found in RBL-2H3 cells following incubation with CA. This evidence demonstrates that CA induces degranulation in RBL-2H3 cells: this process may contribute to anaphylactoid reactions following intravenous injection of CA.
Because anaphylactoid reactions are dose- and concentration-dependent, and this study showed that CA is able to induce degranulation concentration dependently, caution should be exercised when using TCMs containing CA. It is recommended that drug labels should be followed strictly, doses should not be increased casually, and adverse events should be treated rapidly in order to avoid the occurrence of anaphylactoid allergy.
