Introduction

Hoplias malabaricus Bloch, 1794 (Trahira) is widely distributed in South America (Costa et al., 2015), and is abundant in several environments of the Amazon, São Francisco and Paraná hydrographic basins. The dispersion of this piscivorous fish is associated with its capacity to survive for long periods without feeding and to remain in environments with a low concentration of dissolved oxygen (Malabarba, 2006). This Erythrinidae is of considerable economic importance for commercial artisanal fishing in several regions of Brazil (Rodrigues et al., 2017).

A total of 662 species of Trematoda have been found among South American fish, of which 266 species are registered in Brazil (Luque et al., 2017). Among these are the Digenea Ithyoclinostomum dimorphum Diesing, 1850 (Clinostomidae), an endoparasite found during adulthood in the esophagus of birds such as Ardea coo, Nycticorax sp. and Tigrisoma brasiliense. Various species of fish, including H. malabaricus, and mollusks act as intermediate hosts (Dias et al., 2003; Gallio et al., 2007; Benigno et al., 2014). This species of Clinostomidae is the largest worm in this family (Dias et al., 2003), and metacercariae are commonly found in the musculature, gills, pericardium, external wall and esophagus of fish (Gallio et al., 2007; Belei et al., 2013; Benigno et al., 2014). However, there has been no record of ocular infection of fish by this digenea until now. Thus, the objective of this study was to describe the occurrence of I. dimorphum in H. malabaricus and the first record of infection in the eyes of this host from a tributary of the São Francisco River basin (Brazil).

Materials and Methods

In June 2012, twenty-nine specimens of H. malabaricus (19 fema-
les and 10 males) were captured in the upper part of the das Velhas River, a tributary of the São Francisco River, in the state of Minas Gerais, Brazil (44°49'11.20"W, 17°15'8.00"S) (Fig. 1) using gill nets of various mesh sizes. The fish were collected during a survey on the fish and parasitic fauna of the São Francisco River hydrographic basin by the Centro Nacional de Pesquisa e Conservação de Peixes Continentais (CEPTA). Following collection, all fish were weighed (g) and their standard length (SL, cm) was measured. They were then necropsied in loco to collect specimens of the Digenea parasites. All the parasites collected were quantified and stained with carmine acid of Langeron (Amato et al., 1991) and identified in accordance with Travassos et al. (1969).

The permanent slides of the parasites were assembled in Canadian balsam and used to determine the measurements of the reproductive structures in a stereomicroscope (Zeiss model STMI DV 4), with camera and ZEN software. The specimens of *H. malabaricus* were deposited in the fish collection of the Genetics Museum of the Universidade Estadual Paulista (Paulista State University) (UNESP), Botucatu, São Paulo. The ecological terms were those proposed by Bush et al. (1997). Specimens of *I. dimorphum* deposited on fixed glass slides were deposited at the "Adão José Cardoso" Zoology Museum, University of Campinas (UNICAMP), São Paulo, Brazil (N°. ZUEC PLA 155 - *I. dimorphum* in eyes; N°. ZUEC PLA 156 - *I. dimorphum* in intestine and N°. ZUEC PLA 157 - *I. dimorphum* in muscles).

The body weight (g) and total length (cm) data were used to calculate the relative condition factor (Kn) of the parasitized and non-parasitized fish, which was compared using the Mann-Whitney U-test (Zar, 2010). In addition, weight and length data were used to calculate the length-to-weight ratio \( W = aL^b \) of parasitized and non-parasitic fish, after logarithmic transformation of length and weight, and later adjustment along two straight lines, thus obtaining \( \ln y = \ln A + B\ln x \) (Le Cren, 1951).

**Ethical Approval and/or Informed Consent**

The study was carried out in accordance with the principles adopted by the Colégio Brasileiro de Experimento Animal (the Brazilian College of Animal Experimentation) (COBEA). All the fish were collected pursuant to a collection authorization granted by IBAMA/ICMBio - Nº 27447-1/2011.

**Results**

Of the twenty-nine specimens of *H. malabaricus* examined, the eyes (Fig. 2A and B), gut and muscles of 34.5 % (n=10) of the fish were infected by *I. dimorphum* (Fig. 2C), with a mean intensity of 1.1 and mean abundance of 0.4 per host. The prevalence in the intestine was 31.0 % (n=9), with mean intensity of 1.1 and mean abundance of 0.3 per host. In the eyes of the hosts, the prevalence was 3.4 % (n=1), with a mean intensity of 1.0 and a mean abundance of 1.0 per host.

In the right eyeball the metacercaria of *I. dimorphum* was lodged between the cornea and the iris, occupying an area of 0.4 cm², corresponding to 78.0 % of the total organ (Fig. 2C and D).

In *H. malabaricus* analyzed, we found only one *I. dimorphum* infected one eye. Only this *I. dimorphum* we will describe:

*Ithyoclinostominae Yamaguti, 1958*

![Fig. 1. Geographical location of the *Hoplias malabaricus* collection site in a tributary of the São Francisco River, Minas Gerais (Brazil).](image-url)
Ithyoclinostomum Witenberg, 1925

Ithyoclinostomum dimorphum (Diesing, 1850) Witenberg, 1926 (Fig. 3a, b)

General description
Body elongated, flattened (Fig. 3a). Body surface with rounded sensory papillae, furrows and rings forming superficial annulations, dorsal and ventral. Oral sucker, terminal, triangular aperture, surrounded by an expansion of the body wall such as collar-like and radial furrows in the surface (Fig. 3a); pharynx present. Caeca simple, long, without lateral branches or diverticula. Ventral sucker, near anterior extremity of body, close to oral sucker, subtriangular aperture (Figs. 3a). Testes lobed, medians, intercaecals, in the posterior half of body; cirrus-sac, destro anterolateral to anterior testis, intercaecal, internal seminal vesicle coiled (Fig. 3a, b). Genital pore, ventral to cirrus-sac, slightly prominent, surrounded by tegumental rugosities and papillae (Fig. 3b). Ovary, intertesticular (Fig. 3a, b). Uterus, intercecal, originating from the Mehlis’ gland, ascending sinistral to anterior testis reaching uterine sac (Fig. 3a-b). Uterine sac elongated, median, intercaecal. Metraterm, ventro-lateral to cirrus-sac, converging in a genital atrium (Fig. 3b). Vitelline follicles, caecals, extending from hindbody to the end of the first third of body, below cecal bifurcation, confluent on posterior end; vitelloduct anterior to ovary; considerable space free of internal organs between ventral sucker and anterior limit of vitellarium (Fig. 3a). Mehlis’ gland larger than ovary, median, between testis, latero-dorsal to ovary (Fig. 3a, b).
Fig. 3. Metacercaria of *Ithyoclinostomum dimorphum* from *Hoplias malabaricus* from a tributary of the São Franciscos River, Minas Gerais, Brazil. a. Total, ventral view, oral sucker (OS), pharynx (PH), ventral sucker (VS) and intestinal cecum (IC). b. Detail of genital organs, anterior testis (AT), ovary (OV), Mehlis’ gland (MG), uterine sac (US), metraterm (MT), cirrus-sac (CS) and posterior testis (PT). Scale bars in a = 5.0 mm and b = 0.5 mm.
Measurements
Of one specimen from *H. malabaricus* in eye: Body 33.42 long, 3.01 maximum width. Oral sucker 0.62 long, 0.48 wide; Pharynx 0.48 long, 0.42 wide. Ventral sucker 1.34 long, 1.28 wide. Uterine sac 0.23 long, 0.18 wide. Anterior testicle 0.32 long, 0.48 wide. Posterior testicle 0.48 long, 0.63 wide. Ovary 0.30 long, 0.12 wide.

**Taxonomic Summary**
Hosts: *Hoplias malabaricus*.
Locality: São Francisco River in the state of Minas Gerais, Brazil.
Site of infection: Eye of *H. malabaricus*.
Numbers of collected specimens: 1 *I. dimorphum* from *H. malabaricus* in eye.

Table 1. Morphometry (mm) of reproductive structures of metacercariae of *Ithyoclinostomum dimorphum* of the intestine, muscles and right eye of *Hoplias malabaricus* from the tributary of the São Francisco River, Minas Gerais (Brazil).

| Measured structures          | Das Velhas River | Arari Lack, Pará* |
|------------------------------|------------------|-------------------|
|                              | Cavity parasites | Eye parasite      | Cavity parasites |
|                              | (n = 4)          | (n = 1)           | (n = 1)          |
| Mean (range) (mm)            |                  |                   |
| Width of uterine sac         | 0.30 (0.24 – 0.37) | 0.18 | 0.25 |
| Length of uterine sac        | –                | –                 | 2.5              |

| Cirrus sac width             | 0.48 (0.43 – 0.52) | 0.38 | 0.27 |
| Length of cirrus sac         | 0.83 (0.71 – 1.10) | 0.66 | 0.45 |
| Width of anterior testicle   | 0.76 (0.50 – 0.95) | 0.48 | 0.34 |
| Length of anterior testicle  | 0.69 (0.45 – 1.00) | 0.32 | 0.47 |
| Width of posterior testicle  | 0.74 (0.55 – 0.91) | 0.63 | 0.23 |
| Length of posterior testicle | 0.47 (0.34 – 0.56) | 0.48 | 0.45 |
| Width of ovary               | 0.18 (0.15 – 0.25) | 0.12 | 0.12 |
| Ovary length                 | 0.36 (0.27 – 0.45) | 0.30 | 0.18 |
| Width of Mehlis Gland        | 0.59 (0.48 – 0.67) | 0.22 | - |
| Length of Mehlis Gland       | 0.53 (0.44 – 0.69) | 0.41 | - |

* Benigno et al. (2014)
Prevalence: 3.4 %
Abundance: 0.3 per host
Material deposited: From *H. malabaricus* N°. ZUEC PLA 155 - *I. dimorphum* in eye.
The Kn of fish with eyes, intestine and muscles parasitized with *I. dimorphum* (Kn = 0.99) did not differ (U = 86.0, p = 0.68) from that of the non-parasitized fish (Kn = 1.00). The growth of parasitized and non-parasite hosts was allometrically positive (Fig. 4). For the morphometric study of metacercariae of *I. dimorphum* the internal reproductive structures were measured (Fig. 2E). Measurements were taken in mm based on parasites of the eyeball (length 28.43 mm, width 2.54 mm), intestine and muscles (mean length 48.91 mm, mean width 3.35 mm) of the host (Table 1).

**Discussion**

In *H. malabaricus* from the upper das Velhas River, the total prevalence of *I. dimorphum* was similar to that reported for the same host (30.8 %) from the Lagos Reservoir in the state of Rio de Janeiro (Paraguassu & Luque, 2007). However, it was higher than that reported for *H. malabaricus* from the São Francisco River (10.6 %) infected by *Itlycinostomum* sp. (Costa et al., 2015) and from the Arari Lake, in the Ilha do Marajó in the state of Pará (0.9 %), infected by *I. dimorphum* (Benigno et al., 2014). However, these last two studies examined a greater number of *H. malabaricus* specimens than the present study. Poulin (1993) reported that higher prevalence values are related to a more uniform distribution of parasites among hosts, as there is increasing exploitation of the available hosts.

While infection of *H. malabaricus* by metacercariae of *I. dimorphum* has been described in several regions of Brazil, this is the first report of this endoparasite in the ocular region of this host. As the presence of metacercariae of *I. dimorphum* was reported only in the mesentery, musculature, heart, esophagus, cloaca, gills and operculums of host fish (Belei et al., 2013), eyeball parasitism is not fully known. This new site of infection may be due to the sporadic occurrence or behavior of this parasite. Due to the low parasitism of *I. dimorphum*, which occupied almost all of the eyeball, no damage to the prey capturing performance by the host was observed, and the body characteristics of the examined host population were not affected. However, when migrating to the host fish eyes other metacercariae may cause exophthalmos, retinal detachment, cataracts and blindness or even death (Zago et al., 2013; Belei et al., 2013; Ramos et al., 2016) when at high levels of abundance.

The condition factor is based on the relationship between the individual’s weight and length and is an important indicator of fish health, reflecting recent nutritional conditions and interactions between the fish and the biotic and abiotic factors (Le Cren, 1951; Zago et al., 2013). No difference was observed in the Kn of *H. malabaricus* parasitized by *I. dimorphum* and non-parasitized fish due to the low parasite infection in the intestine, eyes and muscles.

Similarly, other studies have also shown that low parasitism by the metacercariae of digeneas did not affect the host condition factor (Paes et al., 2010; Ramos et al., 2016). On the other hand, an increased abundance of metacercariae of *Sphincterodiplostomum musculosum* in *Steindacherina insculpta* caused a reduction in the condition factor of the hosts (Zago et al., 2013), because digenea larvae can be highly pathogenic.

Metacercariae of *I. dimorphum* of the *H. malabaricus* musculature and intestine, the width of the uterine sac, the width and length of the cirrus sac, the anterior and posterior testis length were similar to those described by Benigno et al. (2014); while the values of the width of the anterior and posterior testes were lower. However, the metacercariae of *I. dimorphum* of the ocular region of *H. malabaricus* had smaller measurements to the specimens collected here in the intestine and muscles, as well as in relation to the measurements of the uterine sac and the testis length of the specimens reported by Benigno et al., (2014); while the cirrus sac and width of the anterior and posterior testes had higher values, although the width of the ovary was similar. Such differences may be due to the different methods and measurement tools used in these studies, as well as the methodologies of the treatment of metacercariae for identification. Therefore, standardization of preparation techniques and morphometric measurements in morphometric studies of *metacercariae of I. dimorphum* is required, as this parasite has high body plasticity.

**Conflict of Interest**

Authors state no conflict of interest.
