EQUIVARIANT COBORDISMS BETWEEN FREELY-PERIODIC KNOTS
KEEGAN BOYLE AND JEFFREY MUSYT

ABSTRACT. We consider free symmetries on cobordisms between knots. We classify which freely periodic knots bound equivariant surfaces in the 4-ball in terms of corresponding homology classes in lens spaces. A key tool is the homology cobordism classification of lens spaces using d-invariants. We give a numerical condition determining the free periods for which torus knots bound equivariant surfaces in the 4-ball.

1. Introduction

A knot $K \subset S^3$ is freely $(p, q)$-periodic if there is a free $\mathbb{Z}/p\mathbb{Z}$-action on $S^3$ with quotient $L(p, q)$ which leaves $K$ invariant. An example is shown in Figure 1. Thinking of $S^3$ as the unit sphere in $\mathbb{C}^2$, this symmetry is conjugate to $(z, w) \mapsto (\alpha z, \alpha^q w)$, where $\alpha = e^{2\pi i/p}$.

The goal of this paper is to understand when a freely periodic knot bounds an equivariant orientable surface in $B^4$.

Definition 1. A freely $(p, q)$-periodic knot $K$ is an equivariant boundary if there is a smooth order $p$ extension $\rho : B^4 \to B^4$ of the $\mathbb{Z}/p\mathbb{Z}$ symmetry on $S^3$ and an orientable surface $S$ properly smoothly embedded in $B^4$ with $\rho(S) = S$ and $\partial S = K$.

It is interesting to compare the case of periodic and strongly invertible knots, which always equivariantly bound an orientable surface in $S^3$ (and hence in $B^4$), see for example [BI21, Proposition 1]. On the other hand, freely periodic knots never bound equivariant orientable surfaces in $S^3$, since they would necessarily contain a fixed point by the Lefschetz fixed-point theorem, but the symmetry acts freely on $S^3$.

In this paper we characterize which freely periodic knots equivariantly bound in $B^4$.

Figure 1. A freely $(3, 1)$-periodic diagram for $T(2, 7)$. This diagram consists of three identical tangles and one full twist.
Theorem 1. Let $K \subset S^3$ be a freely $(p, q)$-periodic knot and $\pi : S^3 \to L(p, q)$ be the quotient map. Then $K$ is an equivariant boundary if and only if $\pi(K)$ represents a simple homology class (see Definition 2) in $H_1(L(p, q); \mathbb{Z})$.

Furthermore, we prove that a simple count of strands in a freely periodic diagram determines if the knot equivariantly bounds.

Theorem 2. Let $D$ be an oriented freely $(p, q)$-periodic diagram (see Definition 4) for a knot $K$. Let $m$ be the signed count of strands in $D$. Then $K$ represents a simple homology class in the quotient $L(p, q)$ if and only if $m \equiv \pm 1$ or $m \equiv \pm q^{-1} \pmod{p}$.

In the case of torus knots, this reduces to a numerical condition on the torus knot parameters and the order of the symmetry.

Corollary 1 (Corollary of Theorem 2). A freely $(p, q)$-periodic symmetry of $T(r, s)$ equivariantly bounds if and only if $p$ is a divisor of $r + 1, r - 1, s + 1$, or $s - 1$.

Throughout the paper, all statements are in the smooth category and all surfaces are orientable.

1.1. Acknowledgments. We would like to thank Ahmad Issa for some helpful conversations and Robert Lipshitz for helpful comments on an earlier draft.

2. Freely-periodic knots

Our results are based on considering the homology class which a freely periodic knot represents in the quotient lens space $L(p, q)$. We begin by distinguishing some elements of $H_1(L(p, q))$.

Definition 2. A simple homology class in $H_1(L(p, q); \mathbb{Z})$ is one which is represented by the core of a handlebody in a genus 1 Heegaard splitting.

In fact there is a unique genus 1 Heegaard splitting for $L(p, q)$, see [Bon83], so that there are at most 4 simple homology classes in $H_1(L(p, q))$ coming from the two orientations on the cores of the two handlebodies.

The following proposition is a restatement of [BE12, Lemma 5.2], noting that the lift in $S^3$ of a knot $K$ in $L(p, q)$ is an unknot if and only if $K$ is a rational unknot.

Proposition 1. [BE12, Lemma 5.2] Let $U$ be a freely $(p, q)$-periodic unknot. Then the quotient $\overline{U}$ represents a simple homology class in $H_1(L(p, q))$. Conversely, every simple homology class is represented by the quotient of an unknot.

We now define our main object of study: equivariant cobordisms between freely periodic knots. As we will see in Lemma 2, studying equivariant cobordisms from $K$ to the unknot is equivalent to studying equivariant surfaces with boundary $K$.

Definition 3. An equivariant cobordism $(S^3 \times I, S, \overline{\rho})$ between a freely $(p, q)$-periodic knot $(K, \rho)$ and a freely $(p, q')$-periodic knot $(K', \rho')$ is a proper smooth embedding of a surface $S \to S^3 \times I$ such that $S \cap (S^3 \times \{0\}) = K$ and $S \cap (S^3 \times \{1\}) = K'$, along with a free smooth $\mathbb{Z}/p\mathbb{Z}$ action $\overline{\rho}$ on $S^3 \times I$ which restricts to the freely periodic symmetries $\rho$ on $S^3 \times \{0\}$ and $\rho'$ on $S^3 \times \{1\}$, and leaves $S$ invariant.

To study these cobordisms, it will be convenient to first take the quotient by the free symmetry.
Lemma 1. Let $W = S^3 \times I$, let $\rho$ be a finite order diffeomorphism acting freely on $W$, and let $\overline{\rho}|_{S^3 \times \{0\}} = \rho$ and $\overline{\rho}|_{S^3 \times \{1\}} = \rho'$; for example an equivariant cobordism between freely periodic knots. Then the quotient $\overline{W} = W/\overline{\rho}$ is a homology cobordism between lens spaces.

Proof. Since $S^3 \times I$ is simply connected, $\pi_1(\overline{W}) = \mathbb{Z}/p\mathbb{Z} = H_1(\overline{W})$, and the maps

$$H_1(S^3/\rho) \rightarrow H_1(\overline{W}) \text{ and } H_1(S^3/\rho') \rightarrow H_1(\overline{W})$$

induced by inclusion are isomorphisms. Since $W$ is connected, the same is true for $H_0$ so that $\overline{W}$ is a homology cobordism.

We are interested in the maps induced on homology from these homology cobordisms. The following theorem, which follows from an analysis of the $d$-invariants of lens spaces, is not stated explicitly in [DW15], but follows immediately from their main theorem and [DW15, Lemma 3].

Theorem 3. [DW15] Let $\overline{W} : L(p,q) \rightarrow L(p,q')$ be a homology cobordism. Then $L(p,q)$ is homeomorphic to $L(p,q')$ and $\overline{W}$ induces $\pm \text{Id}$ on $H_1(L(p,q);\mathbb{Z})$.

Corollary 1. Let $K$ be a freely $(p,q)$-periodic knot and $K'$ be a freely $(p,q')$-periodic knot. If there is an equivariant cobordism between $K$ and $K'$, then $q' = \pm q' = \pm q \pm 1 \in \mathbb{Z}/p\mathbb{Z}$. In particular, $K'$ is a freely $(p,q)$-periodic knot.

Proof. Apply Theorem 3 to the quotient of the equivariant cobordism, and use the homeomorphism classification of lens spaces [Bro60].

We now relate equivariant cobordisms to equivariant surfaces for freely periodic knots.

Lemma 2. A freely $(p,q)$-periodic knot $K$ is an equivariant boundary if and only if there is an equivariant cobordism between $K$ and a freely $(p,q)$-periodic unknot.

Proof. Let $S$ be an equivariant surface for $K$ with respect to an order $p$ diffeomorphism $\rho : B^4 \rightarrow B^4$. By classical Smith theory [Smi41], $\rho$ has a contractible fixed-point set $F$. Furthermore, since the fixed set of a self-diffeomorphism is a submanifold, $F$ is a single point. Similarly, the fixed-point set of $\rho|_S$ is also the single point $F$. Removing an equivariant neighborhood $N(F)$ from $B^4$ leaves an $S^3$ boundary component containing an unknot $U$. Hence we have $(S - N(F)) \subset S^3 \times I$ which is preserved by the free $\mathbb{Z}/p\mathbb{Z}$ action and $\partial(S - N(F)) = K \cup U$. That is an equivariant cobordism between $K$ and $U$. By Corollary 1, $U$ comes with a freely $(p,q)$-periodic symmetry.

On the other hand, suppose that we have an equivariant cobordism between $K$ and $U$. By Proposition 1, $U$ can be taken to be the lift of a core of a handlebody in a genus 1 Heegaard decomposition of $L(p,q)$, and in particular the cone of $(S^3,U)$ is a smooth equivariant disk in $B^4$. Gluing this to the cobordism gives an equivariant surface for $K$.

We have all of the tools we need in order to classify which freely periodic knots bound equivariant surfaces in $B^4$.

Theorem 1. Let $K \subset S^3$ be a freely $(p,q)$-periodic knot and $\pi : S^3 \rightarrow L(p,q)$ be the quotient map. Then $K$ is an equivariant boundary if and only if $\pi(K)$ represents a simple homology class (see Definition 2) in $H_1(L(p,q);\mathbb{Z})$.

Proof. Suppose $K \subset S^3$ is a freely $(p,q)$-periodic knot which bounds a surface $S \subset B^4$ which is invariant under an order $p$ diffeomorphism $\rho : B^4 \rightarrow B^4$ with $\rho|_{S^3}$ the free $\mathbb{Z}/p\mathbb{Z}$ action
preserving $K$. Then by Lemma 2 there is an equivariant cobordism from $K$ to a freely $(p,q)$-periodic unknot $U_{p,q}$. By Lemma 1, the quotient of this cobordism is a cobordism of the quotient knots $\overline{K}$ and $\overline{U}_{p,q}$ in a homology cobordism of lens spaces. In particular, there is a map $f : H_1(L(p,q)) \to H_1(L(p,q))$ with $[f(\overline{K})] = [\overline{U}_{p,q}]$ which is induced by a homology cobordism of lens spaces. By Theorem 3, $f = \pm\text{Id}$. Hence $\overline{K}$ represents the same class as an unknot in $H_1(L(p,q))$. Then by Proposition 1, we have that $[\overline{K}]$ is simple.

On the other hand, suppose that $[\overline{K}]$ is simple. Then by Proposition 1, $\overline{K}$ is in the same homology class as the core $\overline{U}$ of a handlebody in the genus 1 Heegaard decomposition of $L(p,q)$, which lifts to a freely periodic unknot $U$. Hence there is a surface $\overline{S}$ in $L(p,q)$ with boundary $\overline{K} \cup \overline{U}$, and lifting $\overline{S}$ to $S^3$ gives us an equivariant surface $S$ with boundary $K \cup U$. We can then take the cone of $(S^3, U)$ with the free symmetry to obtain a smooth equivariant disk in $B^4$. Gluing this to $S$ gives us an equivariant surface for $K$.

We now turn to checking this condition in practice by considering freely periodic knot diagrams, the standard way in which we expect to present a freely periodic knot.

**Definition 4.** A freely $(p,q)$-periodic diagram is the closure of a tangle consisting of the concatenation of $p$ identical tangles and $q$ full twists. See Figures 1, 2, and 3 for examples.

**Theorem 4.** [Chb97, Theorem 1] Every freely $(p,q)$-periodic knot has a freely $(p,q)$-periodic diagram.

From a freely periodic diagram, it is extremely simple to check if the knot is an equivariant boundary.

**Theorem 2.** Let $D$ be an oriented freely $(p,q)$-periodic diagram (see Definition 4) for a knot $K$. Let $m$ be the signed count of strands in $D$. Then $K$ represents a simple homology class in the quotient $L(p,q)$ if and only if $m \equiv \pm 1$ or $m \equiv \pm q^{-1} \pmod p$.

**Proof.** It is clear that a tangle with one strand is homologous to the core $c$ of a genus 1 Heegaard splitting for $L(p,q)$. It follows immediately from the definition of a lens space that the other core is $q^{-1} \cdot c \in H_1(L(p,q))$ so that a diagram with $q^{-1}$ strands is homologous to the other core. \qed

**Remark 1.** Theorem 2 depends on our convention for freely $(p,q)$-periodic diagrams. We could instead switch the role of the two cores in our diagrams so that a freely $(p,q)$-periodic diagram would have $q^{-1}$ full twists. In this case the simple homology classes would be represented by diagrams with $\pm 1$ or $\pm q$ strands.

**Remark 2.** If we instead consider surfaces which need not be orientable, then a version of Theorem 1 using homology with $\mathbb{Z}/2\mathbb{Z}$ coefficients implies that every freely periodic knot bounds a smooth equivariant surface in $B^4$.

We are also interested in the special case of torus knots. We first describe their free symmetries.

**Theorem 5.** There is a freely $(p,q)$-periodic symmetry of $T(r,s)$ if and only if $\gcd(p,rs) = 1$, and $\pm q^{-1} \equiv sr^{-1} \pmod p$. With respect to this symmetry, there is a freely $(p,q)$-periodic diagram on $r$ strands if and only if $\pm q \equiv sr^{-1} \pmod p$. Finally, if $\rho$ and $\rho'$ are two free periods of the same order, then the subgroups of the orientation-preserving diffeomorphism group of the exterior of $T(r,s)$ generated by $\rho$ and $\rho'$ are conjugate.
Proof. By [MS86, Theorem 2.2] and [Sch24] (see also [Kaw96, Exercise 10.6.4]), the freely periodic symmetry preserves a Seifert fibered structure on the exterior of $T(r, s)$, which is a circle bundle over $D(r, s)$, the disk with cone points of orders $r$ and $s$. For $p > 2$, this orbifold has no order $p$ symmetries. For the involution reflecting across an arc containing the two cone points, we must also reflect the fibers to get an orientation-preserving symmetry of the exterior of $T(r, s)$, but this has global fixed points. Thus our free symmetry acts as identity on the base orbifold, and therefore as a rotation on the fibers. In particular, there is a unique symmetry for each $p$.

When $p$ has a common factor with $r$ or $s$, then the order gcd($p, rs$) subgroup has a fixed circle in $S^3$, and so there is no free symmetry of order $p$. On the other hand, the symmetry is free when gcd($p, rs$) = 1. We will describe these free symmetries explicitly. Consider the standard tangle diagram for $T(r, s)$ with $r$ strands. Then there are $s$ total twists, which can be grouped as $\pm q$ full twists and $p$ concatenated tangles of $n$ twists each (see Figure 2 for an example). Hence $s = \pm q \cdot r + n \cdot p$ from which we deduce that $\pm q \equiv sr^{-1} \pmod{p}$. However, a free $(p, q)$-symmetry can also be regarded as a free $(p, q^{-1})$-symmetry (c.f. the homeomorphism classification of lens spaces). In particular the diagram with $s$ strands has $\pm q \equiv rs^{-1} \pmod{p}$. □

Theorem 2 gives us the following entirely numerical corollary when considering torus knots.

**Corollary 1** (Corollary of Theorem 2). A freely $(p, q)$-periodic symmetry of $T(r, s)$ equivariantly bounds if and only if $p$ is a divisor of $r + 1, r - 1, s + 1,$ or $s - 1$.

Proof. Consider the freely $(p, q)$-periodic diagram for $T(r, s)$ with $r$ strands which consists of $s$ total twists: $\pm q$ full twists and $p$ tangles of $n$ twists each. By Theorem 1 and Theorem 2, $T(r, s)$ is an equivariant boundary if and only if $r \equiv \pm 1$ or $r \equiv \pm q^{-1} \pmod{p}$. By Theorem 5, $\pm q \equiv sr^{-1} \pmod{p}$ so that $p$ is a divisor of $r - 1, r + 1, s - 1,$ or $s + 1$. □

**Remark 3.** Note that a freely $(2, q)$ or $(3, q)$-periodic knot is always an equivariant boundary by Theorem 2.

Our final result is the observation that the genus of an equivariant surface for a freely periodic knot must be a multiple of $p$.

**Theorem 6.** Let $S$ be an equivariant surface for a freely $(p, q)$-periodic knot. Then the genus of $S$ is a multiple of $p$.

Proof. Let $n$ be the genus of $S$ so that $\chi(S) = 1 - 2n$. Since $S$ has exactly one fixed point $F$ (see the proof of Lemma 2), $\chi(S - F) = -2n$. Quotienting $S - F$ by the free $\mathbb{Z}/p\mathbb{Z}$ action leaves a surface $\overline{S}$ with $\chi(\overline{S}) = -2n/p$. But since $\overline{S}$ has exactly two boundary components, it must have an even Euler characteristic and so $p|n$. □

### 3. Examples and Questions

We conclude with some examples and questions.

**Example 1.** Consider the torus knot $T(2, 7)$. It has a unique free period of order 3 which is shown in Figure 2. By Corollary 1, $T(2, 7)$ bounds an invariant surface in $B^4$ with respect to its free $(3, 2)$-period. This surface can be seen directly from Figure 1, where changing the sign of the crossing in the bottom of each of the 3 tangle boxes gives an equivariant genus 3 cobordism to the unknot, which then bounds an equivariant disk in $B^4$. Note that by Theorem 6, this is the minimum possible genus for such a surface, since $T(2, 7)$ is not slice.
Example 2. Consider the torus knot $T(2, 3)$. Since there are no primes which divide 1, 3, 2, or 4 and are relatively prime to 2 and 3, Corollary 1 implies that $T(2, 3)$ does not equivariantly bound with respect to any of its infinitely many free symmetries.

Example 3. Consider the freely $(5,1)$-periodic knot $K$ shown in Figure 3. It has a signed count of 2 strands, so by Theorem 1 and Theorem 2, $K$ does not bound an equivariant surface in $B^4$.

In principle one could use Theorem 1 and Theorem 2 to show that some freely-periodic slice knots do not bound equivariant surfaces (let alone disks). However, every freely-periodic slice knot we know of represents a simple homology class in the quotient lens space.

Question 1. What tools can give a lower bound on the genus of an equivariant surface for a freely-periodic knot? Does there exist a freely-periodic slice knot which does not bound any equivariant disk?

Our main result requires methods relying on smooth topology. However, we do not know of a freely $(p,q)$-periodic knot which does not represent a simple homology class in $L(p,q)$, but which is an equivariant boundary in the topologically locally flat category.

Question 2. Does Theorem 1 hold in the topological category?
