Recently a mechanism to generate mass from gravitational interaction, based on Mach principle, according to which the inertia of a body is a property of matter as well as of the background provided by the rest-of-the-universe was presented in [1] [2]. In these papers such an idea was realized for scalar and spinor fields treating the rest-of-the-universe in its vacuum state. In the present paper, using an extended version of Mach principle, the same strategy will be applied to show how the Heisenberg-Nambu-Jona-Lasinio non-linear equation for fermions $\Psi$ arises as a consequence of the gravitational interaction of $\Psi$ with the rest-of-the-universe.

PACS numbers:

I. INTRODUCTION

Although the theory of General Relativity may be understood as completely independent from the Machian idea that inertia of a body $\Lambda$ is related to the global distribution of energy of all particles existing in the universe, we must recognize its historical value in the making the ideology that enabled Einstein to start his journey toward the construction of a theory of gravitation [3] [4].

During the 20th century, the idea of associating the dependence of local characteristics of matter with the global state of the universe came up now and then but without producing any reliable mechanism that could support such proposal.

Even the concept of mass – that pervades all gravitational processes – did not find a realization of such dependence on global structure of the universe. On the contrary, the most efficient mechanism and one that has performed an important role in the field of micro-physics came from elsewhere, namely the attempt to unify forces of a non-gravitational character, such as long-range electrodynamics with decaying phenomena described by weak interaction. Indeed, the Higgs model produced an efficient scenario for generating mass to the gauge fields.

For our purpose here it is enough to analyze the non-linear equation of motion that they used in their original paper as the basis of their theory which is

$$i\gamma^\mu \nabla_\mu \Psi - 2s(\Lambda + i B \gamma^5)\Psi = 0$$

This equation, as remarked by these authors, was proposed earlier by Heisenberg [8] although in a quite different context. We will not enter in the analysis of the theory that follows from this dynamics. Our question here is just this: is it possible to produce a model such...
that HNJL (Heisenberg-Nambu-Jona-Lasinio) equation for spinor field becomes a consequence of the gravitational interaction of a free massless Dirac field with the rest-of-the-universe? I claim that the answer is yes. This article was written to prove this.

II. THE COSMOLOGICAL INFLUENCE ON THE MICROPHYSICAL WORLD: THE CASE OF CHIRAL-INvariant HEISENBERG-NAMBU-JONA-LASINIO DYNAMICS

We take Mach’s principle as the statement according to which the inertial properties of a body \( \mathcal{A} \) are determined by the energy-momentum throughout all space. The description of such universal state that takes into account the whole contribution of the rest-of-the-universe onto \( \mathcal{A} \) is the most homogeneous one and is related to what Einstein attributed to the cosmological constant or, in modern language, the vacuum of all remaining bodies. We follow a similar procedure here and will consider that the Extended Mach Principle (EMP) means that the influence of the rest-of-the-universe on any elementary field in microphysics can be described through the identification of the energy-momentum distribution of all remaining bodies under the form

\[
T_{\mu\nu}^U = \Lambda g_{\mu\nu}
\]

A. Non minimal coupling with gravity

In the framework of General Relativity we set the dynamics of a fermion field \( \Psi \) coupled non-minimally with gravity to be given by the Lagrangian (we are using units were \( \hbar = c = 1 \))

\[
L = L_D + \frac{1}{\kappa} R + V(X) R - \frac{1}{\kappa} \Lambda + L_{CT}
\]

where

\[
L_D \equiv \frac{i}{2} \bar{\Psi} \gamma^\mu \nabla_\mu \Psi - \frac{i}{2} \nabla_\mu \bar{\Psi} \gamma^\mu \Psi
\]

The non-minimal coupling of the spinor field with gravity is contained in the term \( V(X) \) and depends on the scalar \( X \) defined by

\[
X = A^2 + B^2
\]

where \( A = \bar{\Psi} \) and \( B = i \bar{\Psi} \gamma^5 \). We note that we can write, in an equivalent way,

\[
X = J_\mu J^\mu
\]

where \( J^\mu = \bar{\Psi} \gamma^\mu \Psi \). This quantity \( X \) is chiral invariant, once it is invariant under the map

\[
\Psi' = \gamma^5 \Psi.
\]

Indeed, from this \( \gamma^5 \) transformation, it follows

\[
A' = -A, \; B' = -B; \; \text{then}, \; X' = X.
\]

The case in which the theory breaks chiral invariance the potential \( V \) depends only on the invariant \( A \) – and it is the road to the appearance of a mass. Here we start from the beginning with a chiral invariant theory. For the time being the dependence of \( V \) on \( X \) is not fixed. We have added \( L_{CT} \) to counter-balance the terms of the form \( \partial_\lambda X \partial^\lambda X \) and \( \Box X \) that appear due to the gravitational interaction. The most general form of this counter-term is

\[
L_{CT} = H(X) \partial_\mu X \partial^\mu X
\]

We shall see that \( H \) depends on \( V \) and if we set \( V = 0 \) then \( H \) vanishes. This dynamics represents a massless spinor field coupled non-minimally with gravity. The cosmological constant is added by the reasons presented above and as we shall see it represents the influence of the rest-of-the-universe on \( \Psi \).

Independent variation of \( \Psi \) and \( g_{\mu\nu} \) yields

\[
i \gamma^\mu \nabla_\mu \Psi + \Omega \left( A + i B \gamma^5 \right) \Psi = 0
\]

where

\[
\Omega \equiv 2 R V' - 2 H' \partial_\mu X \partial^\mu X - 4 H \Box X
\]

\[
\alpha_0 \left( R_{\mu\nu} - \frac{1}{2} R g_{\mu\nu} \right) = -T_{\mu\nu}
\]

where we set \( \alpha_0 \equiv 2/\kappa \) and \( V' \equiv \partial V/\partial X \). The energy-momentum tensor defined by

\[
T_{\mu\nu} = \frac{2}{\sqrt{-g}} \frac{\delta (\sqrt{-g} L)}{\delta g^{\mu\nu}}
\]

is given by

\[
T_{\mu\nu} = \frac{i}{4} \bar{\Psi} \gamma_{(\mu} \nabla_{\nu)} \Psi - \frac{i}{4} \nabla_{(\mu} \bar{\Psi} \gamma_{\nu)} \Psi
\]

\[
+ 2 V (R_{\mu\nu} - \frac{1}{2} R g_{\mu\nu}) \nabla_\mu V - 2 \Box V g_{\mu\nu}
\]

\[
+ 2 H \partial_\mu X \partial_\nu X - H \partial_\lambda \partial^\lambda X g_{\mu\nu} + \frac{\alpha_0}{2} \Lambda g_{\mu\nu}
\]

Taking the trace of equation (6), after some simplification and using

\[
\Box V = V' \Box X + V'' \partial_\mu X \partial^\mu X
\]

it follows

\[
(\alpha_0 + 2 V + 2 V' X) R = (4 H X - 6 V') \Box X
\]

\[
+ (2 H' X - 6 V'' - 2 H) \partial_\alpha X \partial^\alpha X
\]

\[
+ 2 \alpha_0 \Lambda
\]
Then
\[
\Omega = (M \Box X + N \partial_\mu X \partial^\mu X) + \frac{4 \alpha_0 \Lambda V'}{\alpha_0 + 2V + 2V' X} \tag{9}
\]
where
\[
M = \frac{2V'(4HX - 6V')}{\alpha_0 + 2V + 2V' X} - 4H
\]
\[
N = \frac{2V'(2XH' - 6V'' - 2H)}{\alpha_0 + 2V + 2V' X} - 2H'
\]

Defining \(\Delta = \alpha_0 + 2V + 2V' X\) we re-write \(M\) and \(N\) as
\[
M = -\frac{4}{\Delta} (3V'^2 + H (\alpha_0 + 2V))
\]
\[
N = -\frac{2}{\Delta} (3V'^2 + H (\alpha_0 + 2V))'
\]

Inserting this result on the equation (11) yields
\[
i\gamma^\mu \nabla_\mu \Psi + (M \Box X + N \partial_\lambda X \partial^\lambda X) \Psi + Z (A + iB \gamma^5) \Psi = 0 \tag{10}
\]
where
\[
Z = \frac{4 \alpha_0 \Lambda V'}{\alpha_0 + 2V + 2V' X}
\]

At this stage it is worth to select among all possible candidates of \(V\) and \(H\) particular ones that makes the factor on the gradient and on \(\Box\) of the field to disappear from equation (10).

The simplest way is to set \(M = N = 0\), which is satisfied if
\[
H = -\frac{3 V'^2}{\alpha_0 + 2V}
\]

Imposing that \(Z\) must reduce to a constant we obtain
\[
V = \frac{1}{\kappa} \left[ \frac{1}{1 + \beta X} - 1 \right]. \tag{11}
\]

As a consequence of this,
\[
H = -\frac{3 \beta^2}{2\kappa} \frac{1}{(1 + \beta X)^3} \tag{12}
\]

where \(\beta\) is a constant. Note that \(V\) vanishes when \(\beta = 0\), and as a consequence, \(H\) vanishes too.

The equation for the spinor becomes
\[
i\gamma^\mu \nabla_\mu \Psi - 2s (A + iB \gamma^5) \Psi = 0 \tag{13}
\]

where
\[
s = \frac{2 \beta \Lambda}{\kappa (\hbar c)}, \tag{14}
\]

Thus as a result of the above process the field satisfies Heisenberg-Nambu-Jona-Lasinio equation of motion. This is possible due to the influence of the rest-of-the-Universe on \(\Psi\). If \(\Lambda\) vanishes then the constant of the self-interaction of \(\Psi\) vanishes. This is precisely what we envisaged to obtain: the net effect of the non-minimal coupling of gravity with the spinor field corresponds to a specific self-interaction. The HNJL equation of motion appears only if we take into account the existence of all remaining bodies in the universe — represented by the cosmological constant — in the state in which all existing matter is on the corresponding vacuum.

The various steps of our mechanism can be synthesized as follows:

- The dynamics of a massless spinor field \(\Psi\) is described by the Lagrangian
  \[
  L_D = \frac{i}{2} \bar{\Psi} \gamma^\mu \nabla_\mu \Psi - \frac{i}{2} \nabla_\mu \bar{\Psi} \gamma^\mu \Psi;
  \]
- Gravity is described in General Relativity by the scalar of curvature
  \[
  L_E = R;
  \]
- The field interacts with gravity in a non-minimal way described by the term
  \[
  L_{int} = V(X) R
  \]
  where \(X = A^2 + B^2\) and \(A = \bar{\Psi} \Psi\) and \(B = i\bar{\Psi} \gamma^5 \Psi\)
- The action of the rest-of-the-universe on the spinor field, through the gravitational intermediary, is contained in the form of an additional constant term on the Lagrangian noted as \(A\):
- A counter-term depending on the invariant \(X\) is introduced to kill extra terms coming from gravitational interaction;
- As a result of this process, after choosing \(V\) and \(H\) the field acquires a self-interaction term and its equation of motion is precisely Heisenberg-Nambu-Jona-Lasinio described as
  \[
  i\gamma^\mu \nabla_\mu \Psi - 2s (A + iB \gamma^5) \Psi = 0
  \]
  where \(s\) is given by equation (14) and is zero only if the cosmological constant vanishes.

It is not hard to envisage others situations in which the above mechanism can be further applied. Then the question appears: how far one can extend this argument? We will come back to this in a future work.
III. CONCLUSION

In this paper we considered the influence of all the material content of the universe on a fermionic field when this content is in two possible states: in one case its energy distribution is zero; in another case it is in a vacuum state represented by the homogeneous distribution $T_{\mu\nu} = \Lambda g_{\mu\nu}$. In the first case the dynamics of the field is independent of the global properties of the universe and is described by the massless Dirac equation

$$i\gamma^\mu \nabla_\mu \Psi = 0$$

In the second case, the rest-of-the-universe induces on field $\Psi$ the Heisenberg-Nambu-Jona-Lasinio non-linear dynamics

$$i\gamma^\mu \nabla_\mu \Psi - 2s (A + iB\gamma^5) \Psi = 0.$$

Thus, the scenario presented in this paper led us to consider the idea that microphysics can depend strongly on the global structure of the universe.

IV. ACKNOWLEDGEMENTS

I would like to thank FINEP, CNPq and FAPERJ for financial support. I thank Ugo Moschella for conversations on the Nambu-Jona-Lasinio paper.
