The calibration process aims to guarantee that a measurement device is to follow the established standards. The purpose of this study is to design an automatic leak test for digital pressure meter in which the function of this device is to measure pressure on the sphygmomanometer and suction pump or other devices that use pressure parameters for measurement. This study used the Arduino as a control system, and to process the analog data into digital. Signal conditioning, based on the amplifier circuit, was also applied for the MPX5050GP and MPXV4115VC6U sensor. The proposed design used a 4x20 liquid crystal display to show the parameters in this design were also equipped with a selector of mmHg or kPa units. The result shows that the fluctuating resolution is 0.25 mmHg. In this design, an automatic leak feature was also equipped for the sphygmomanometer. The results obtained an average error of 7.3 mmHg for sphygmomanometers. On the other hand, the suction pumps have an accuracy of less than 1.5 kPa. From these results, it was concluded that this design could be used for the measurement of devices that use positive pressure and negative pressure.

I. INTRODUCTION

Sphygmomanometers have several observer error variables and devices used, which make measurement error problems and become a discussion during public health [1]. Discussions such as the correct method, the most common errors, the size, and the proportion of fixed cuffs in the search for more reliable measuring devices that show patients' true blood pressure [2]. The results of blood pressure measurements carried out with mercury are different from the results of measurements made with a digital sphygmomanometer. With differences in measurement results, it is necessary to identify blood pressure gauges. The results of blood pressure measurements must be done correctly, this is because of health concerns and patient safety. Errors in blood pressure measurement can be caused by human error or the function of the device itself whose accuracy has exceeded the allowable threshold (Standard error of up to 3 mmHg) [3]. The maximum error permitted for blood pressure measurements anywhere on the scale range should be ± 0.4 kPa (± 3 mmHg) in the case of first time verification and ± 0.5 kPa (± 4 mmHg) for the sphygmomanometer used [4].

The design of this DPM has been carried out by several previous researchers, Junia Dyah Pernata Wibisono in 2017 made this module but only with one mode, namely vacuum pressure [5]. Then in 2018 Yosep Kurniawan made a two-mode DPM module but the weakness of this module lies in the measurement unit only one parameter, the use of the same negative sensor MPXV4115 but the difference in positive pressure [6]. Then in 2019 there were two people who made the DPM module namely Ryan Nur Rokhman and Abdul Cholid who made the same DPM in two modes and still used one measurement parameter, mmHg [7] [8]. Inadequate sphygmomanometer treatment and calibration are common causes of systematic errors in blood pressure measurement. The only way to reduce systematic errors is to use correct measurement techniques and instruments that are well maintained and calibrated [9]. Suction Pump is a medical...
device that functions to suck out liquids that are not needed by the body in the operation process, such as blood, stomach contents, and so on. Then the liquid that is sucked is collected in a container. The working principle of the Suction Pump is that the motor will rotate along with the suction fan so that it can suck the fluid in the patient's body through the suction hose which is connected through a tube and filter [10].

Based on what has been described, the researcher will add the measurement unit parameters into two, mmHg and Kpa, and will add a leakage test automatically, because tensimeter calibration requires a leak test because it is very important to know whether tensimeter is still feasible or not. In addition to the leak test, there are 2 measurement times, namely 60 seconds and 5 minutes, this refers to Permenkes.

II. MATERIALS AND METHODS

A. Experimental Setup

This study uses a sphygmomanometer and suction pump subject that has been calibrated and the data is taken once

B. Materials and Device

In this study using MPX5050GP sensor made by Freescale semiconductor in Texas America for positive pressure reading while for negative pressure reading using MPXV4115VC6U sensor made by Motorola Semiconductor product in America, In both sensors an appropriate capacitor was added with the datasheet on the sensor. In processing the output of the sensor using ARDUINO NANO ATmega 328 on pins A1 and A2, before processing the output first goes to the buffer circuit, for the power supply in this module uses 2 lithium polymer batteries, and all results will be displayed on a 4x20 character LCD.

C. Experiment

In this study, researchers conducted a calibration of the sphygmomanometer and suction pump using a module that has been made, namely two-mode DPM with 2 units of measurement, namely mmHg and Kpa

![Flowchart](image)

**Fig 1. The diagram block of the Pulse Oximetry**

**Fig 2. The Flowchart of the Arduino Program**

There is also a selection of leak tests for the sphygmomanometer after the selection is complete and push-button enter is pressed then the sensor will start reading. The following is a flowchart of the module (Fig. 2).
F. Circuit

1) Circuit of minimum system

Analog data from the sensor is converted to digital data by Arduino via PIN A0 (for positive pressure) and PIN A1 (for negative pressure). The 4x20 LCD is used to display the pressure data that has been taken. UP and DOWN selection buttons are used to select the desired pressure positive or negative pressure besides this button is also used for the selection of mmHg or Kpa units. When logic is high, the program will detect the presence of input on a digital pin and then the program will run a reading mechanism on the input pin variable which is processed in such a way that the equation is obtained so that a positive or negative pressure reading occurs (Fig. 3).

2) Circuit of MPX5050GP

Input in the sensor circuit is pressure, the pressure captured by the sensor will be converted to a voltage (Fig. 4). In this type of sensor, the results of the ratio of pressure and voltage are directly proportional so that the resulting value is higher the pressure the higher the output results.

3) Circuit of MPXV4115VC6U

Input in the sensor circuit is pressure, the pressure captured by the sensor will be converted to a voltage (Fig. 5). In this type of sensor, the results of the ratio of pressure and voltage are directly proportional so that the resulting value is higher the pressure the higher the output results.

III. RESULTS

In this study using a sphygmomanometer and suction pump as a comparison and module parameters, and the units taken in this study are mmHg and KPa for positive or negative pressure.

A. Results of DPM Design

A sphygmomanometer design was shown in Fig. 6. It is equipped with LCD 4 x 16 character and four button for user interaction.
B. Program listing for positive pressure sensor readings

```
LOOP:
total = total - readings[readIndex];
readings[readIndex] = analogRead(A2);
total = total + readings[readIndex];
readIndex = readIndex + 1;
IF (readIndex >= numReadings) THEN
    readIndex = 0;
ENDIF
average = total / numReadings;
int sensorValue = average;
int sensorValue = average;
voltage=(sensorValue*(voltageMax/sensorMax));
p=((voltage)/0.09) - nkp;
mmHg1=(average*0.3723+9.6355) - nul;
pp=mmHg1;
ENDLOOP
```

The above program functions as initialization of a positive pressure reading on the MPX5050GP sensor from the microcontroller and also as an ADC smoothing program on the sensor with evenly distributed 10 ADC reading data.

C. Program listing for negative pressure sensor readings

```
LOOP:
int sensorValue2 = analogRead(A0);
voltage2=(sensorValue2*(voltageMax/sensorMax));
p2=(((voltage2-5.1)/0.039)-10)-nkp2;
mmHg2=(p2*7.50062)-nul2;
np=mmHg2;
ENDLOOP
```

The above program is a program for TFT LCD and sensor initialize MAX30102 to be able to communicate with the microcontroller. TFT LCD with 9600 baud rate and sensor using a baud rate 115200.

D. Listing program for Display Menu

```
WHILE (1)
lcd.setCursor(7, 0); //pengaturan tampilan
lcd.print("MENU");
lcd.setCursor(4, 1);
lcd.print(">PENGUKURAN<");
lcd.setCursor(5, 2);
lcd.print("KEBOCORAN");
```

```
sensor();
waktu(),
delay(200);
enter=digitalRead(2);
up=digitalRead(4);
down=digitalRead(6);
IF (enter==HIGH) THEN
    delay(200);
lcd.clear();
goto menupmp;
ENDIF
IF (up==HIGH) THEN
    delay(200);
lcd.clear();
goto menukc;
ENDIF
IF (down==HIGH) THEN
    delay(200);
lcd.clear();
goto menukc;
ENDIF
ENDWHILE
```

The menu program above there are various kinds according to needs and in the program created there are menus for each mode, namely a menu for measuring positive, negative, mmHg, kPa, and leak tests.

E. Listing program for Timer

```
LOOP:
IF (state==1) THEN
    unsigned long waktu = millis();
ENDIF
IF (waktu - waktusekarang > 1000)
    waktusekarang = millis();
detik++;
ENDIF
IF (detik > 59) THEN
    menit++;
detik = 0;
ENDIF
IF (menit > 59) THEN
    menit = 0;
ENDIF
```

The menu program above there are various kinds according to needs and in the program created there are menus for each mode, namely a menu for measuring positive, negative, mmHg, kPa, and leak tests.

Journal homepage: http://jeeemi.org/index.php/jeeemi/index
A timer program using the system counter on millis (). With millions of reading for 1000 times, a value of 1 second will be obtained and a reading of more than 60 seconds will produce 1 minute. The conditions in the last line are used to stop the timer.

F. Measurement results chart

The device was calibrated using standard pressure meter to show the accuracy of the machine. The measurement was performed for positive, negative and difference unit (kPa) as shown in Fig 7, Fig. 8 and Fig. 9, respectively.

| -12             | -12.2              | 0.2          |
| -14             | -14.1              | 0.1          |
| -16             | -15.9              | 0.1          |

IV. DISCUSSION

In the DPM module that is made using positive and negative pressure measurements, this module has 2 units of measurement namely mmHg and kPa for the measurement of the sphygmomanometer and suction pump, the disadvantage of the module being made is that the power in the battery runs out quickly.

V. CONCLUSION

Overall this study can conclude that for positive pressure data taken only once and can be seen error values if averaged each measurement obtained a value of 7.3 mmHg. And for negative pressure with mmHg units the higher the value taken; the error generated on the device is also greater. Whereas at the negative pressure the kPa unit the higher the value has taken the smaller the error produced.
